**Important Notices and Disclaimers:** Publication of this handbook is for the purpose of circulating information and opinion among those concerned for fire and electrical safety and related subjects. While every effort has been made to achieve a work of high quality, neither the NFPA® nor the contributors to this handbook guarantee or warrant the accuracy or completeness of or assume any liability in connection with the information and opinions contained in this handbook. The NFPA and the contributors shall in no event be liable for any personal injury, property, or other damages of any nature whatsoever, whether special, indirect, consequential, or compensatory, directly or indirectly resulting from the publication, use of, or reliance upon this handbook.

This handbook is published with the understanding that the NFPA and the contributors to this handbook are supplying information and opinion but are not attempting to render engineering or other professional services. If such services are required, the assistance of an appropriate professional should be sought.

NFPA 101®, *Life Safety Code*® (“NFPA 101”), is, like all NFPA codes, standards, recommended practices, and guides (“NFPA Standards”), made available for use subject to Important Notices and Legal Disclaimers, which appear at the end of this handbook and can also be viewed at [www.nfpa.org/disclaimers](http://www.nfpa.org/disclaimers).

**Notice Concerning Code Interpretations:** This thirteenth edition of the *Life Safety Code*® Handbook is based on the 2015 edition of NFPA 101. All NFPA codes, standards, recommended practices, and guides (“NFPA Standards”) are developed in accordance with the published procedures of the NFPA by technical committees comprised of volunteers drawn from a broad array of relevant interests. The handbook contains the complete text of NFPA 101 and any applicable Formal Interpretations issued by the NFPA at the time of publication. This NFPA Standard is accompanied by explanatory commentary and other supplementary materials.

The commentary and supplementary materials in this handbook are not a part of the NFPA Standard and do not constitute Formal Interpretations of the NFPA (which can be obtained only through requests processed by the responsible technical committees in accordance with the published procedures of the NFPA). The commentary and supplementary materials, therefore, solely reflect the personal opinions of the editor or other contributors and do not necessarily represent the official position of the NFPA or its technical committees.

#### REMINDER: UPDATING OF NFPA STANDARDS

NFPA 101, *Life Safety Code*, like all NFPA codes, standards, recommended practices, and guides (“NFPA Standards”), may be amended from time to time through the issuance of Tentative Interim Amendments or corrected by Errata. An official NFPA Standard at any point in time consists of the current edition of the document together with any Tentative Interim Amendment and any Errata then in effect. In order to determine whether an NFPA Standard has been amended through the issuance of Tentative Interim Amendments or corrected by Errata, visit the Document Information Pages on NFPA’s website. The Document Information Pages provide up-to-date, document specific information including any issued Tentative Interim Amendments and Errata. To access the Document Information Page for a specific NFPA Standard go to <http://www.nfpa.org/document> for a list of NFPA Standards, and click on the appropriate Standard number (e.g., NFPA 101). In addition to posting all existing Tentative Interim Amendments and Errata, the Document Information Page also includes the option to sign-up for an “Alert” feature to receive an email notification when new updates and other information are posted regarding the document.

## Using Basic Search, Advanced Search, and Find

### **Basic Search**

Search across all content. Open the search window in one of three ways:

1. Select "search" under the Edit menu *or*
2. With the Acrobat toolbar displayed at the top of the screen, click the drop-down arrow to the right of the Find box in the Acrobat toolbar and select "open full Acrobat search" from the list that drops down (you can toggle basic search criteria on and off in this menu, too) *or*
3. Use the keyboard shortcut SHIFT + CTRL + F.

Enter your search term in the box provided. Basic Search includes checkbox options for "whole words only" and "case-sensitive" searches. Be sure the radio button specifies "in the current PDF document" (this is the default selection for the radio button). A list of search results displays in its own resizable window. Clicking on a list item makes the text (where the term was found) appear in the PDF window.

### **Advanced Search**

From the bottom of the basic search window, choose "use advanced search options" to narrow the search using additional criteria. Options in the advanced search window include matching the exact word or phrase, matching only some of the words, and stemming (see below).

**Stemming** finds words that contain part (the stem) of a specified search word. For example, a search for *opening* would find instances of *open*, *opened*, *opens*, and *openly*. Wildcard characters (\* or ?) are not permitted in stemming searches. Stemming isn't available if either "whole words only" or "case-sensitive" is selected.

*Note: While this PDF allows searching across all codes at once, you can customize your search to favor only one document. Before beginning a search, navigate to the desired document or section so it is displayed in the PDF window. The search will begin at the document or section that appears in the PDF window and display the results found in that document at the top of the list.*

### **Find**

Find a word or term in the codes in one of two ways:

1. Select "find" under the Edit menu (the checkboxes for "whole words only" and "case-sensitive" are the same as in Basic Search above) *or*
2. With the Acrobat toolbar displayed at the top of the screen, place the cursor in the Find box in the Acrobat toolbar and type a word or term in that box. To specify "whole words only" or "case-sensitive," use the drop-down arrow to the right of the Find box and toggle these criteria on or off in the list there.

The found term will be highlighted in the text. To go to other occurrences of the term, use the "find previous" and "find next" icons that appear beside the Find box in the Acrobat toolbar.

About the Editors ix

## PART 1

*Life Safety Code*® and Commentary 1

### 1 Administration 3

- 1.1 Scope 3
- 1.2 Purpose 7
- 1.3 Application 8
- 1.4 Equivalency 8
- 1.5 Units and Formulas 10
- 1.6 Enforcement 11

### 2 Referenced Publications 13

- 2.1 General 13
- 2.2 NFPA Publications 14
- 2.3 Other Publications 15
- 2.4 References for Extracts in Mandatory Sections 18

### 3 Definitions 19

- 3.1 General 19
- 3.2 NFPA Official Definitions 19
- 3.3 General Definitions 20

### 4 General 55

- 4.1 Goals 55
- 4.2 Objectives 56
- 4.3 Assumptions 57
- 4.4 Life Safety Compliance Options 57
- 4.5 Fundamental Requirements 59
- 4.6 General Requirements 60
- 4.7 Fire Drills 69
- 4.8 Emergency Action Plan 70

### 5 Performance-Based Option 75

- 5.1 General Requirements 76
- 5.2 Performance Criteria 79
- 5.3 Retained Prescriptive Requirements 81

- 5.4 Design Specifications and Other Conditions 81
- 5.5 Design Fire Scenarios 93
- 5.6 Evaluation of Proposed Designs 100
- 5.7 Safety Factors 104
- 5.8 Documentation Requirements 105

### 6 Classification of Occupancy and Hazard of Contents 107

- 6.1 Classification of Occupancy 107
- 6.2 Hazard of Contents 125

### 7 Means of Egress 129

- 7.1 General 130
- 7.2 Means of Egress Components 148
- 7.3 Capacity of Means of Egress 257
- 7.4 Number of Means of Egress 270
- 7.5 Arrangement of Means of Egress 273
- 7.6 Measurement of Travel Distance to Exits 285
- 7.7 Discharge from Exits 290
- 7.8 Illumination of Means of Egress 293
- 7.9 Emergency Lighting 296
- 7.10 Marking of Means of Egress 299
- 7.11 Special Provisions for Occupancies with High Hazard Contents 308
- 7.12 Mechanical Equipment Rooms, Boiler Rooms, and Furnace Rooms 309
- 7.13 Normally Unoccupied Building Service Equipment Support Areas 310
- 7.14 Occupant Evacuation Elevators 311

### 8 Features of Fire Protection 321

- 8.1 General 321
- 8.2 Construction and Compartmentation 321
- 8.3 Fire Barriers 328
- 8.4 Smoke Partitions 339
- 8.5 Smoke Barriers 340
- 8.6 Vertical Openings 345
- 8.7 Special Hazard Protection 366
- 8.8 Inspection and Testing of Door Assemblies 369

## 9 Building Service and Fire Protection Equipment 373

- 9.1 Utilities 373
- 9.2 Heating, Ventilating, and Air-Conditioning 374
- 9.3 Smoke Control 375
- 9.4 Elevators, Escalators, and Conveyors 376
- 9.5 Waste Chutes, Incinerators, and Laundry Chutes 380
- 9.6 Fire Detection, Alarm, and Communications Systems 381
- 9.7 Automatic Sprinklers 398
- 9.8 Other Automatic Extinguishing Equipment 401
- 9.9 Portable Fire Extinguishers 402
- 9.10 Standpipe Systems 402
- 9.11 Fire Protection System Operating Features 403
- 9.12 Carbon Monoxide (CO) Detection and Warning Equipment 403
- 9.13 Special Inspections and Tests 404

## 10 Interior Finish, Contents, and Furnishings 407

- 10.1 General 407
- 10.2 Interior Finish 409
- 10.3 Contents and Furnishings 429

## 11 Special Structures and High-Rise Buildings 437

- 11.1 General Requirements 438
- 11.2 Open Structures 438
- 11.3 Towers 439
- 11.4 Water-Surrounded Structures 443
- 11.5 Piers 443
- 11.6 Vehicles and Vessels 444
- 11.7 Underground and Limited Access Structures 444
- 11.8 High-Rise Buildings 446
- 11.9 Permanent Membrane Structures 450
- 11.10 Temporary Membrane Structures 452
- 11.11 Tents 454

## 12/13 New and Existing Assembly Occupancies 457

- 12.1/13.1 General Requirements 460
- 12.2/13.2 Means of Egress Requirements 475

- 12.3/13.3 Protection 523
- 12.4/13.4 Special Provisions 534
- 12.5/13.5 Building Services 570
- 12.6/13.6 Reserved 571
- 12.7/13.7 Operating Features 571

## 14/15 New and Existing Educational Occupancies 589

- 14.1/15.1 General Requirements 589
- 14.2/15.2 Means of Egress Requirements 594
- 14.3/15.3 Protection 610
- 14.4/15.4 Special Provisions 622
- 14.5/15.5 Building Services 624
- 14.6/15.6 Reserved 626
- 14.7/15.7 Operating Features 626

## 16/17 New and Existing Day-Care Occupancies 631

- 16.1/17.1 General Requirements 631
- 16.2/17.2 Means of Egress Requirements 642
- 16.3/17.3 Protection 652
- 16.4/17.4 Special Provisions 659
- 16.5/17.5 Building Services 661
- 16.6/17.6 Day-Care Homes 661
- 16.7/17.7 Operating Features 668

## 18/19 New and Existing Health Care Occupancies 675

- 18.1/19.1 General Requirements 676
- 18.2/19.2 Means of Egress Requirements 695
- 18.3/19.3 Protection 739
- 18.4/19.4 Special Provisions 784
- 18.5/19.5 Building Services 792
- 18.6/19.6 Reserved 795
- 18.7/19.7 Operating Features 796

## 20/21 New and Existing Ambulatory Health Care Occupancies 807

- 20.1/21.1 General Requirements 808
- 20.2/21.2 Means of Egress Requirements 817
- 20.3/21.3 Protection 828
- 20.4/21.4 Special Provisions 837
- 20.5/21.5 Building Services 841
- 20.6/21.6 Reserved 842

# Preface

For almost 90 years, the National Fire Protection Association has been the developer and publisher of the *Life Safety Code*<sup>®</sup>. Formerly known as the *Building Exits Code*, the *Code* is prepared by the NFPA Committees on Safety to Life — 14 of the nearly 300 technical committees operating within the framework of NFPA's consensus standards-development system. The members of the Committees on Safety to Life bring to the committee deliberations their knowledge and competence in the design and construction of buildings and structures, in the manufacture and testing of building components and accessories, in the life safety-related abilities and needs of occupants of all occupancy types, and in the enforcement of regulations pertaining to life safety from fire and other related hazards encountered in buildings and structures. The committee members also participate in the development of *NFPA 5000*<sup>®</sup>, *Building Construction and Safety Code*<sup>®</sup>, which is processed in the same revision cycle as *NFPA 101*<sup>®</sup>. There are many similarities between the two codes, especially within the occupancy chapters.

The *Life Safety Code* is a unique document; its contents address specific requirements that have a direct influence on safety to life in both new construction and existing buildings — not new construction alone. Moreover, although the *Code*'s paramount concern is life safety and not protection of property per se, there are also — by observance of the *Code*'s requirements — ancillary benefits to mission continuity and property protection.

The impact that application of the *Code* can have on saving lives is difficult to measure; however, it is reasonable to assume that its influence is extremely significant. For example, of the many fatal public building fires investigated by NFPA, invariably one or more of the building features contributing to loss of life from fire were in violation of the requirements of the *Code*.

NFPA recognizes that a code suitable for enforcement must, by the nature of its purpose, be concise and without explanatory text. In addition, a code cannot be written to cover every situation that will be encountered; thus, it must be applied with judgment and used with good sense and with an awareness of the rationale

for the requirements to be enforced. A little help and counsel along the way can make the job a lot easier; hence, NFPA has also developed this *Life Safety Code Handbook*.

This handbook gives users of the *Life Safety Code* background information on the reasons for certain *Code* provisions. It also provides some suggestions, through its text, illustrations, and photos, on how some *Code* requirements can be implemented effectively. This kind of information is intended to provide users of the *Code* with a better understanding of, and appreciation for, the requirements contained in the *Code*. The net result should be the better design, operation, and evaluation of buildings and structures that are increasingly more fire safe. The reader is cautioned, however, to look upon the commentary that appears in the handbook as the views of the editors and — where commentary reads relatively the same as in earlier editions — the contributors to earlier editions of the handbook. The commentary does not necessarily reflect the official position of NFPA.

Where a pair of occupancy chapters addresses a given occupancy (for example, **Chapter 12** for new assembly occupancies and **Chapter 13** for existing assembly occupancies), the *Code* text for both chapters is presented in side-by-side columns to permit easy comparison. Further, the accompanying commentary points out differences between the provisions applicable to new construction and to existing buildings.

For this edition of the handbook, Gregory Harrington revised the commentary for **Chapters 8 through 11, 24, 26, 28 through 33, 36 through 40, and 42**; Ron Coté revised the commentary for **Chapters 1 through 7, 12 through 23, and 43, and Annex B**.

NFPA

# About the Editors

## **Ron Coté, P.E.**

Ron Coté, P.E., is the principal life safety engineer in the Building Fire Protection and Life Safety group at NFPA. He joined the NFPA staff in 1981 and serves as staff liaison and secretary to several Safety to Life and Building Code technical committees. Prior to his employment with NFPA, Ron worked for seven years as a fire protection engineer for Factory Mutual Research Corporation. Ron is a registered Professional Engineer in the discipline of Fire Protection in the Commonwealth of Massachusetts.

## **Gregory E. Harrington, P.E.**

Gregory E. Harrington, P.E., is a principal fire protection engineer in the NFPA Building Fire Protection and Life Safety group. He serves as staff liaison and secretary to several Safety to Life and Building Code technical committees, as well as staff liaison to the NFPA 1, *Fire Code*, technical committee. Prior to joining the NFPA staff in 1996, Greg worked as a fire protection engineer with the San Antonio, Texas, Fire Department and as a consulting engineer with Schirmer Engineering Corporation (now Aon Fire Protection Engineering). He holds the degree of Master of Science in Fire Protection Engineering from Worcester Polytechnic Institute and is a registered Professional Engineer in the discipline of Fire Protection in the State of Connecticut.

## In Memoriam

Dr. John L. Bryan

As we finalized this edition of the handbook, we learned that Dr. John L. Bryan, Professor Emeritus at the University of Maryland's Department of Fire Protection Engineering, died on October 13, 2014 at the age of 87. Dr. Bryan, known as Prof to the many engineers who graduated from the fire protection engineering program that he started at the University, was an active, life-long member of NFPA. He served more than 40 years on the Technical Committee on Means of Egress and the Correlating Committee on Safety to Life, including its predecessor — the Technical Committee on Safety to Life. Dr. Bryan chaired the NFPA Standards Council and its Board of Directors.

In 1986, he received NFPA's Paul C. Lamb Award, established to honor members whose service to NFPA characterizes the height of volunteer spirit and deed, and in 2005, received NFPA's Standards Medal, the highest award given by the Standards Council, which recognizes outstanding contributions to fire safety in the development of codes and standards. He also received the Society of Fire Protection Engineer's "Fire Protection Man of the Year" honor in 1977.

I had the pleasure of instructing *Life Safety Code*<sup>®</sup> seminars with John Bryan. In the 1980s and early 1990s we teamed up each year, typically in November, to present the seminar in Denver. John's wife Sarah usually made the trip as their daughter Joan was living in the Denver area. I looked forward to the group dinners. One night we arrived at a restaurant only to learn that it was Election Day and that cocktails could not be served until the polls closed. The group took tacit direction from John and did not order food until we were able to toast the day's events with a drink. The hour wait, replete with servers refilling water glasses and offering more bread, passed quickly. I will miss you, John.

*Ron Coté*

*October 16, 2014*

# *Life Safety Code*<sup>®</sup> and Commentary

Part One of this handbook includes the complete text of the 2015 *Life Safety Code*<sup>®</sup>, which is made up of mandatory chapters (**Chapters 1** through **43**) and nonmandatory annex material. The 14 committees on safety to life prepared the mandatory provisions found in **Chapters 1** through **43** within the framework of NFPA's consensus standards–development system. Because these provisions are designed to be suitable for adoption into law, or for reference by other codes and standards, the text is concise, without extended explanation.

The committees on safety to life also developed the material found in Annex A, and **Annex B** of the *Code*. The material in Annex A is designed to assist users in interpreting the mandatory *Code* provisions. It is not considered to be part of the requirements of the *Code*; it is advisory or informational. An asterisk (\*) following a *Code* paragraph number indicates that nonmandatory material pertaining to that paragraph appears in Annex A. For readers' convenience, in this handbook, Annex A material has been interspersed to appear immediately following its base paragraph in the body of the mandatory *Code* text. The material in **Annex B** is written in mandatory language, but applies only where specifically adopted.

The handbook editors — Ron Coté, P.E., and Gregory Harrington, P.E. — prepared the explanatory commentary that accompanies the *Code* and **Annex B**. The commentary follows the *Code* text it discusses and is easily identified by blue type. Designed to help users understand and apply *Code* provisions, the commentary gives detailed explanations of the reasoning behind *Code* requirements, examples of calculations, applications of requirements, and tables of useful information. More than 750 drawings and photographs show practical applications of specific *Code* provisions. Used together with the *Code*, the commentary provides a rich resource for assessing the level of life safety from fires in buildings.

# Administration

NFPA 101®, *Life Safety Code*®, is an occupancy-based document that is written and formatted so the user may go directly to the applicable occupancy chapter (i.e., Chapters 12 through 42), provided that the user is familiar enough with the occupancy classification criteria of Section 6.1 to classify the occupancy correctly. The applicable occupancy chapter provides a complete road map to direct the user to all needed portions of the core chapters, which develop the basic life safety concepts and offer a host of protection tools, systems, and features. The core chapters are positioned at the front of the *Code* in Chapters 1 through 11 and in Chapter 43 on building rehabilitation. A student of the *Code* might read and study the *Code* in chapter order, but the average user will typically consult an occupancy chapter first and then reference only those portions of the core chapters that apply to the project at hand, as directed by the occupancy chapter.

The basic philosophy and core requirements of the *Code* are presented in Chapters 1 through 11 and Chapter 43. The scope, purpose, and application of the *Code* are positioned in Chapter 1 to allow the building blocks or fundamentals of the *Code* to be described, understood, and correctly applied.

Although any part of this handbook might be relevant and directly applicable to a specific type of structure or occupancy, the user is encouraged to develop a sound understanding of the rudimentary concepts of occupant life safety. Such understanding includes recognizing where the *Code* applies and the extent to which the designer, authority having jurisdiction (AHJ), or both, should apply the *Code* requirements for new versus existing buildings. See, for example, 1.3.1 and its associated annex material.

The long-standing recognition of “equivalency” (see Section 1.4) is also an important concept, not only in NFPA 101 but also in the NFPA codes and standards used in combination with NFPA 101. The equivalency concept allows for innovative approaches to life safety and fire safety. Although the *Code* is a comprehensive document, it is conceivable that a situation that the *Code* does not contemplate might arise. Equivalency considerations allow for such a situation to be evaluated and for a mutually agreeable solution to be developed that would provide the same or better level of life safety than that which would result from strict compliance with the prescriptive requirements.

## 1.1\* Scope

Annex A is not a part of the requirements of this NFPA document but is included for informational purposes only. This annex

contains explanatory material, numbered to correspond with the applicable text paragraphs.

**A.1.1** The following is a suggested procedure for determining the *Code* requirements for a building or structure:

- (1) Determine the occupancy classification by referring to the occupancy definitions in Chapter 6 and the occupancy Chapters 12 through 42. (See 6.1.14 for buildings with more than one use.)
- (2) Determine if the building or structure is new or existing. (See the definitions in Chapter 3.)
- (3) Determine the occupant load. (See 7.3.1.)
- (4) Determine the hazard of contents. (See Section 6.2.)
- (5) Refer to the applicable occupancy chapter of the *Code*, Chapters 12 through 42. [See Chapters 1 through 4 and Chapters 6 through 11, as needed, for general information (such as definitions) or as directed by the occupancy chapter.]
- (6) Determine the occupancy subclassification or special use condition, if any, by referring to Chapters 16 and 17, day-care occupancies; Chapters 18 and 19, health care occupancies; Chapters 22 and 23, detention and correctional occupancies; Chapters 28 and 29, hotels and dormitories; Chapters 32 and 33, residential board and care occupancies; Chapters 36 and 37, mercantile occupancies; and Chapter 40, industrial occupancies, which contain subclassifications or special use definitions.
- (7) Proceed through the applicable occupancy chapter to verify compliance with each referenced section, subsection, paragraph, subparagraph, and referenced codes, standards, and other documents.
- (8) Where two or more requirements apply, refer to the occupancy chapter, which generally takes precedence over the base Chapters 1 through 4 and Chapters 6 through 11.
- (9) Where two or more occupancy chapters apply, such as in a mixed occupancy (see 6.1.14), apply the most restrictive requirements.

The steps outlined in A.1.1 were developed to help the user determine which *Code* requirements might apply to a given building if the more prevalent, prescriptive, specification-based life safety systems option is used. If the performance-based option is used, see 4.4.3.

Because specific occupancy requirements are detailed in separate chapters, the *Code* user should first identify the proper occupancy classification for a building. Guidance on classifying occupancy is presented in Section 6.1. The *Code*

user will then be able to determine the appropriate chapter(s) for that occupancy.

### Example 1: Determining Code Requirements

A jewelry retail sales operation (i.e., a jewelry store) occupying all of the twelfth floor of a multitenant building uses 5000 ft<sup>2</sup> (465 m<sup>2</sup>), or 95 percent, of the floor area for sales purposes. Using the occupancy classification criteria and definitions found in Section 6.1, the jewelry store should be classified as a mercantile occupancy (see 6.1.10.1). In determining that the floor is a mercantile occupancy, the Code user narrows the range of choice of applicable occupancy chapters from Chapters 12 through 42 to the two that specifically address mercantile occupancies — Chapters 36 and 37.

Using the definition of *existing building* found in 3.3.36.5, the user can determine whether the building is subject to the requirements for new construction or for existing buildings. If the jewelry store used in this example was occupied subsequent to the adoption of the Code currently being enforced, the user determines that the life safety features required are those that apply to new construction. Thus, the user could narrow the applicable occupancy requirements to those for new mercantile occupancies as detailed in Chapter 36.

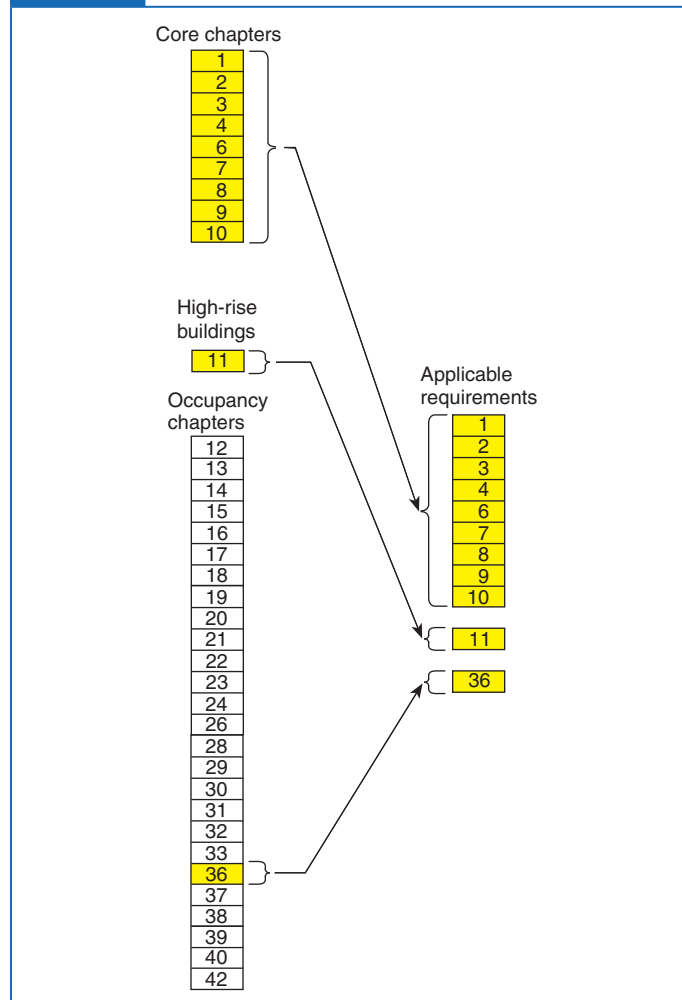

The Code user next identifies the subclassification of the mercantile occupancy (see 36.1.2.2) as Class A, Class B, or Class C on the basis of the 5000 ft<sup>2</sup> (465 m<sup>2</sup>) floor area used for sales purposes. Because the jewelry store occupies more than 3000 ft<sup>2</sup> (280 m<sup>2</sup>), but less than 30,000 ft<sup>2</sup> (2800 m<sup>2</sup>), it is classified as a Class B mercantile occupancy. The user then locates the requirements of Chapter 36 that specifically apply to Class B mercantile occupancies and those requirements that apply across all subclassifications of mercantile occupancies. The user notes that Chapter 36 does not repeat the requirements found in Chapters 1 through 4 and Chapters 6 through 10, because the Code mandatorily references the use of those chapters. Because the jewelry store is located in the high-rise portion of the building, 36.4.2 requires compliance with the high-rise building requirements of Section 11.8.

In this example, the Code user recognizes that the requirements of Chapters 1 through 4, Chapters 6 through 10, a portion of Chapter 11, and Chapter 36 apply and are required to be met. This selection process is outlined in Exhibit 1.1.

### Example 2: Determining Code Requirements

Consider a two-story mall building where two tenant spaces formerly occupied by a shoe store and a children's clothing store [each with 5000 ft<sup>2</sup> (465 m<sup>2</sup>) of floor area for sales purposes] are to be gutted, combined in area, and outfitted for a new tenant that will sell sporting goods. The new tenant will occupy 10,000 ft<sup>2</sup> (929 m<sup>2</sup>) of floor area for sales purposes. The Code user first identifies that the rehabilitation work will require compliance with the provisions of Chapter 43, Building Rehabilitation, and that such work falls into the rehabilitation category of

Exhibit 1.1

Selecting specification-based code requirements that apply to a given occupancy; in this case, a new mercantile occupancy on the twelfth floor of a multitenant building.

modification, as explained further in this example (see 43.2.2.1.3 and Section 43.5). The user also notes that the occupancy involved is mercantile.

Next, the Code user consults the mercantile occupancy subclassification criteria of 36.1.2.2 or 37.1.2.2. The previous tenants were both Class B mercantile occupancies. The new tenant that will occupy the combined spaces of the previous tenants will be a Class B mercantile occupancy. The modification does not involve a change in mercantile subclassification, so the provisions of 36.1.1.6 and 37.1.1.6 do not mandate compliance with the requirements for new construction.

Chapter 43 is consulted to learn whether Chapter 36 for new mercantile occupancies or Chapter 37 for existing mercantile occupancies is to be used. Per 43.1.1, the rehabilitation to be performed must be classified as repair, renovation, modification, or reconstruction work. The reconfiguration of the space leads to classifying the work as a modification (see 43.2.2.1.3).

Per 43.1.2.1(1), for a modification, the requirements of the applicable existing occupancy chapter must be met. Thus, the provisions of Chapter 37 for existing mercantile occupancies are required as the base requirements for starting the rehabilitation of the tenant space.

Per 43.5.1.3, newly constructed elements, components, and systems must comply with the requirements of other sections of the Code applicable to new construction; therefore, portions of Chapter 36 for new mercantile occupancies also will apply.

As explained in Example 1, the requirements of Chapters 1 through 4 and Chapters 6 through 10 must be met.

In Example 2, the Code user recognizes that the requirements of Chapters 1 through 4, Chapters 6 through 10, some portions of Chapter 36, Chapter 37, and some portions of Chapter 43 apply and are required to be met. This selection process is outlined in Exhibit 1.2.

**1.1.1 Title.** NFPA 101, *Life Safety Code*, shall be known as the *Life Safety Code*<sup>®</sup>, is cited as such, and shall be referred to herein as “this Code” or “the Code.”

The title of the Code was changed from *Building Exits Code to Code for Safety to Life from Fire in Buildings and Structures* in 1966. The change in title expanded the scope of the Code from a specification-based code for stairs, doors, and fire escapes to a performance- and specification-based code that addresses the myriad factors that affect life safety in the event of fire.

From 1966 through 2002, the Code was referred to by its shortened name, *Life Safety Code*<sup>®</sup>. In 2003, the Code was officially renamed *Life Safety Code*.

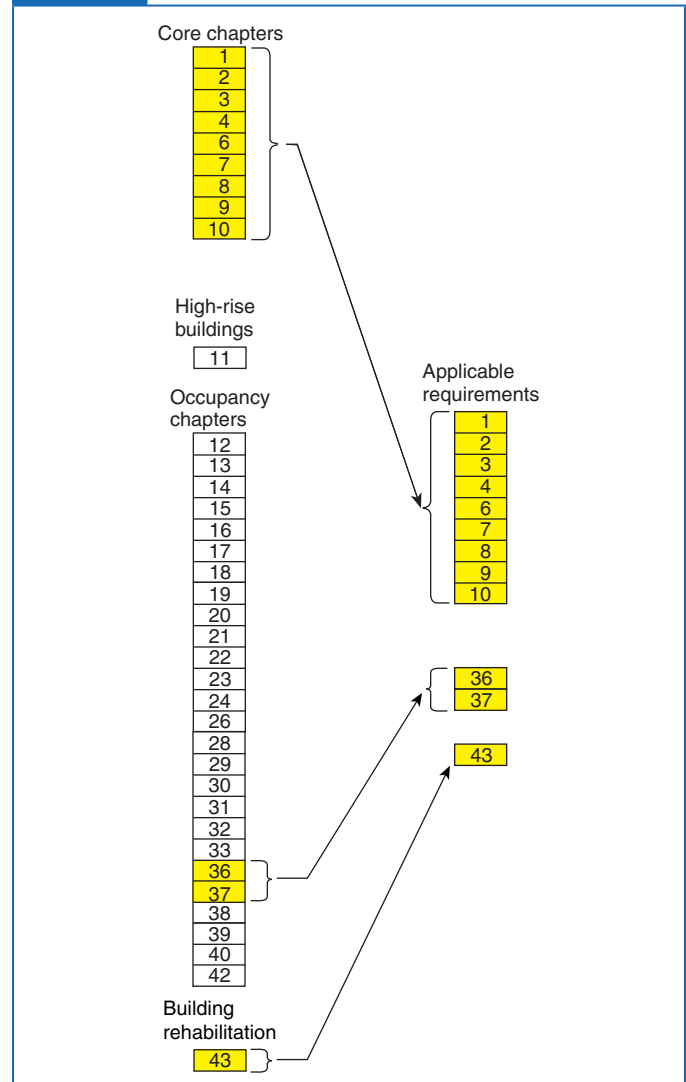

The change in title reflects the Code’s ever-changing content. In some cases, the Code addresses non-fire, day-to-day, building occupant use issues. For example, in 12.2.5.4.3 and 13.2.5.4.3, which apply to assembly occupancies, access and egress routes are required to be maintained so that crowd management, security, and emergency medical personnel are able to reach any individual at any time without undue hindrance.

**1.1.2 Danger to Life from Fire.** The Code addresses those construction, protection, and occupancy features necessary to minimize danger to life from the effects of fire, including smoke, heat, and toxic gases created during a fire.

Subsection 1.1.2 does not list panic as a danger arising from the effects of a fire that needs to be addressed specifically via Code requirements. Panic is not a typical reaction of occupants in a burning building that at least comes close to being Code compliant. Studies of building fires indicate that occupants typically exhibit altruistic behavior toward others. Human response to a threatening situation might follow one of a variety of behaviors. Individuals might choose to investigate, sound an alarm, assist with rescue, seek help, or flee. Such actions constitute normal behavior, even when taken collectively. Most people avoid direct contact with a fire while undertaking another action.

In February of 2003, a fire at The Station nightclub in West Warwick, Rhode Island, claimed 100 patrons’ lives. The fire began

**Exhibit 1.2**

Selecting specification-based Code requirements that apply to a given occupancy; in this case, a new mercantile tenant fit-out in a mall building space formerly occupied by two mercantile tenants.

when pyrotechnics ignited the exposed, acoustical foamed plastic panels that lined the walls and ceiling of a platform serving as a stage for a musical group performing to a capacity crowd. Patrons died as the fire spread faster than they could egress the building. More than 30 bodies were found blocking the main entrance/exit. Some reviewers of the disaster might judge the patrons as having panicked, while others might say the patrons behaved rationally in trying to move toward the exits but were hindered when their actions created a crowd crush. Patron behavior was not the problem. The problem stemmed from the facility being far from Code compliant. The pyrotechnic devices (gerbs) used were designed for a venue with a much higher ceiling. The exposed foamed plastic panels lining the walls and ceiling of the performers’ platform were a prohibited material and

noted as a distinct hazard by existing *Code* requirements applicable to interior wall and ceiling finish.

Crowd behavior in large assembly occupancy venues is difficult to predict and manage. The life safety evaluation required of large assembly occupancies by the provisions of [Chapters 12 and 13](#) deals not only with fire but also with storm, collapse, crowd behavior, and other related factors, a list of which is provided in [A.12.4.1.3](#) and [A.13.4.1.3](#). Crowd managers are required in all assembly occupancies by the provisions of [12.7.6](#) and [13.7.6](#).

**1.1.3 Egress Facilities.** The *Code* establishes minimum criteria for the design of egress facilities so as to allow prompt escape of occupants from buildings or, where desirable, into safe areas within buildings.

Relocating building occupants to safe areas within a building might include moving them as follows:

1. Into an area of refuge
2. Through doors in a horizontal exit that lead into another fire compartment
3. Through doors in a smoke barrier that lead into another smoke compartment

In some cases, an egress system that relies on total evacuation to the exterior is not practical. For example, in a health care occupancy, building evacuation might expose patients to conditions more dangerous than those encountered in relocating the patients from a fire compartment to a safe smoke compartment on the same floor. For most occupancies, the *Code* provisions permit the designer to choose whether the egress system relies on full evacuation. For occupancies such as health care, a protect-in-place strategy is used that requires the subdivision of floors into two or more smoke compartments, regardless of the presence of fire exit stairs.

For high-rise buildings, egress systems have traditionally been implemented so as to rely on partial building evacuation/relocation. Occupants on the fire floor and the floors immediately above and below the fire floor are asked to relocate to floors a few levels below the fire floor. This procedure is intended to preclude having to direct all building occupants to evacuate immediately to ground level until the fire conditions dictate such action. Following the September 11, 2001, collapse of the World Trade Center towers in New York City, occupants of high-rise buildings have reported a reluctance to stay behind at the first hint of a fire or similar problem. Building managers and code consultants need to re-evaluate high-rise building emergency plans that rely on partial evacuation or relocation. See [A.4.8.2.1\(3\)](#) for detailed guidance on occupant evacuation strategies.

**1.1.4 Other Fire-Related Considerations.** The *Code* addresses other considerations that are essential to life safety in recognition of the fact that life safety is more than a matter of egress. The *Code* also addresses protective features and systems, building services, operating features, maintenance activities, and other provisions in recognition of the fact that achieving an

acceptable degree of life safety depends on additional safeguards to provide adequate egress time or protection for people exposed to fire.

**1.1.5\* Considerations Not Related to Fire.** The *Code* also addresses other considerations that, while important in fire conditions, provide an ongoing benefit in other conditions of use, including non-fire emergencies.

**A.1.1.5** Life safety in buildings includes more than safety from fire. Although fire safety has been the long-standing focus of NFPA *101*, its widely known title, *Life Safety Code*, and its technical requirements respond to a wider range of concerns, including, for example, crowd safety. *Code* requirements that contribute to the safe movement of people during fire emergencies might also assist in responding to many other hazards that require decisions about where people can be safely located.

Numerous elements affect the overall level of life safety. The *Code* addresses many of these factors, including combustibility of interior finishes and the evacuation preparedness of occupants. However, other areas are not addressed, such as the influence of public education on fire safety. See [1.1.6](#) and related commentary for more information on factors not covered by the *Code*.

**1.1.6 Areas Not Addressed.** The *Code* does not address the following:

- (1)\* General fire prevention or building construction features that are normally a function of fire prevention codes and building codes
- (2) Prevention of injury incurred by an individual due to that individual's failure to use reasonable care
- (3) Preservation of property from loss by fire

**A.1.1.6(1)** This *Code* is intended to be adopted and used as part of a comprehensive program of building regulations that include building, mechanical, plumbing, electrical, fuel gas, fire prevention, and land use regulations.

The *Code* is not intended to be either a building code or a fire prevention code. However, in the interest of public safety, the *Code* does contain provisions typically associated with a building code or fire prevention code. For example, although construction requirements are typically considered the domain of a building code, [Chapters 18 and 19](#) provide minimum, fire-rated construction requirements for buildings housing health care occupancies. The construction requirements are provided to ensure the structural integrity of the building so that occupants can be protected in-place, following relocation within the building, for a period well into a fire incident. Where building evacuation becomes necessary, the construction requirements help to maintain structural integrity for what can be expected to be a very lengthy period of time required for staff to evacuate those occupants incapable of self-preservation.

Similarly, the provisions of [Chapters 12 and 13](#) — for assembly occupancies — require fire-rated building construction,

depending on the number of occupants and the levels of the building occupied as assembly occupancies. The requirement recognizes the lengthy time periods necessary to evacuate large numbers of persons, especially from floors above the level of exit discharge. Thus, fire-rated building construction is intended to ensure the structural integrity of the building for the period of time required for occupants to evacuate.

Although preventative measures are typically associated with a fire prevention code, the operating features sections located at the end of most of the occupancy chapters contain requirements that do the following:

1. Limit the flammability of contents introduced into certain occupancies
2. Require the training of facility employees in emergency duties
3. Require occupants to practice emergency egress and relocation

These operational requirements, when combined with egress and other specific occupancy chapter requirements, provide an appropriate life safety package.

The *Code* intentionally excludes traditional building code topics such as wind loads, seismic considerations, and exterior exposure protection.

Although the *Code* requirements were developed to provide life safety from fire, adherence to its requirements might assist in property conservation and prevention of personal injuries. For example, the automatic sprinkler systems required for life safety purposes provide substantial property protection benefits as well.

## 1.2\* Purpose

The purpose of this *Code* is to provide minimum requirements, with due regard to function, for the design, operation, and maintenance of buildings and structures for safety to life from fire. Its provisions will also aid life safety in similar emergencies.

This *Code* specifies the minimum requirements that collectively help to ensure safety to occupants from fires and similar emergencies to the degree specified by the objectives stated in [Section 4.2](#). However, it is not the *Code's* intent to prevent the user from exceeding the specified minimum requirements. See also [4.6.8](#).

**A.1.2** The *Code* endeavors to avoid requirements that might involve unreasonable hardships or unnecessary inconvenience or interference with the normal use and occupancy of a building but provides for fire safety consistent with the public interest.

Protection of occupants is achieved by the combination of prevention, protection, egress, and other features, with due regard to the capabilities and reliability of the features involved. The

level of life safety from fire is defined through requirements directed at the following:

- (1) Prevention of ignition
- (2) Detection of fire
- (3) Control of fire development
- (4) Confinement of the effects of fire
- (5) Extinguishment of fire
- (6) Provision of refuge or evacuation facilities, or both
- (7) Staff reaction
- (8) Provision of fire safety information to occupants

Buildings are normally designed to accommodate a specific functional need. The *Code* considers the normal occupancy of a building and attempts not to interfere with its regular use or to set requirements that cause unreasonable hardship or unnecessary inconvenience to its normal functioning. For example, although self-closing devices on doors help to ensure continuous fire and smoke compartmentation, the health care occupancy provisions of this *Code* do not require self-closing devices on patient room doors because of the day-to-day functional need for staff to monitor conditions, which necessitates that doors remain open. The health care occupancy chapters achieve the intended minimum level of life safety, without unduly interfering with normal operation of the facility, by combining other features and protection schemes. For example, [18.7.2](#) and [19.7.2](#), which apply to new and existing health care occupancies, respectively, require that staff establish procedures to be followed in case of fire, including closing doors to isolate the fire area and confine the effects of the fire.

In addressing life safety from fire and similar emergencies, the *Code* focuses on the movement of people in an emergency. However, many of the building features that assist with the safe movement of people in an emergency also provide increased safety during normal building use. For example, new stairs are not permitted to have a riser height that exceeds 7 in. (180 mm) or to provide a tread depth less than 11 in. (280 mm) to reduce the potential to trip under emergency egress use. This safe stair geometry also reduces the potential of tripping whenever the stair is used.

The occupancy chapters make varying use of any or all of the protection features in [A.1.2\(1\)](#) through [\(8\)](#). A business occupancy located in a single-story building uses fewer of the protection features to accomplish the intended minimum level of life safety than does a health care occupancy. A health care occupancy accomplishes its minimum level of life safety by extensively applying the features of [A.1.2\(1\)](#) through [\(7\)](#) using a defend-in-place strategy. This strategy recognizes that some occupants of a health care occupancy are both incapable of self-preservation and difficult to move, particularly to other floors or to the exterior of the building. The provision of [A.1.2\(8\)](#) for providing safety information to occupants is not an important requirement for a health care occupancy, because it is expected that staff will direct any needed relocation or evacuation so as to relieve the patients from having to know how to relocate or evacuate by themselves.

## 1.3 Application

**1.3.1\* New and Existing Buildings and Structures.** The *Code* shall apply to both new construction and existing buildings and existing structures.

**A.1.3.1** Various chapters contain specific provisions for existing buildings and structures that might differ from those for new construction.

In order to provide a minimum level of life safety to all occupancies in all structures, the *Code* applies to both new construction and existing buildings. **Exhibit 1.3** depicts new construction. **Exhibit 1.4** depicts an existing building. Provisions exist throughout the *Code* that apply specifically to existing buildings. Such provisions should be thought of as applying to existing conditions. Also, the *Code* contains requirements for new construction that have been modified to apply to existing buildings. The modifications were made to limit the resulting disruption and financial impact on existing buildings while providing the intended minimum level of life safety. The requirements applicable to new construction are often more stringent than those for existing buildings, because providing appropriate life safety requirements is considered less disruptive and more cost-effective during construction. If no modification for existing buildings appears within a *Code* requirement, the same provision applies for new construction and existing buildings (i.e., existing situations).

See also **4.6.5**, **4.6.6**, and **4.6.9** and the definitions of *existing* and *existing building* in **3.3.81** and **3.3.36.5**, respectively.

**Exhibit 1.3**

*New construction (East Tower of Rush University Medical Center in Chicago, IL). (Courtesy of Leo T. Garcia, Rush Photo Group)*

**1.3.2 Vehicles and Vessels.** The *Code* shall apply to vehicles, vessels, or other similar conveyances, as specified in **Section 11.6**, in which case such vehicles and vessels shall be treated as buildings.

**Exhibit 1.4**

*Existing building. (Courtesy of Brown Palace Hotel, Denver, CO)*

## 1.4\* Equivalency

Nothing in this *Code* is intended to prevent the use of systems, methods, or devices of equivalent or superior quality, strength, fire resistance, effectiveness, durability, and safety over those prescribed by this *Code*.

**A.1.4** Before a particular mathematical fire model or evaluation system is used, its purpose and limitations need to be known. The technical documentation should clearly identify any assumptions included in the evaluation. Also, it is the intent of the Committee on Safety to Life to recognize that future editions of this *Code* are a further refinement of this edition and earlier editions. The changes in future editions will reflect the continuing input of the fire protection/life safety community in its attempt to meet the purpose stated in this *Code*.

**Section 1.4**, Equivalency, presents a powerful design alternative that permits individual and multiple specification-based requirements to be satisfied by components and systems that the authority having jurisdiction is convinced meet the goals, objectives, and intended level of life safety of the *Code*. Where all life safety systems, rather than individual and multiple specification-based systems, are engineered to meet the goals and objectives of the *Code*, true performance-based design is permitted in accordance with **Chapter 5**. In other words, equivalency deals with discrete, manageable pieces of the overall life safety

system; performance-based design treats the system as a whole. See [Section 4.4](#).

With each new edition, the *Code* continues its evolution from a specification-based code to a performance-oriented code. [Section 4.4](#) permits a complete performance-based design approach in accordance with [Chapter 5](#). However, the traditional, widely accepted, specification-based approach is maintained as an option. The vast majority of building projects will continue to use this traditional approach. The performance-based design approach is complex and expensive and, therefore, feasible for megasized developments.

[Section 1.4](#) recognizes that, although the majority of the *Code* uses specification language as the basis for enforcement, it should not inhibit the use of alternate or equivalent systems or design approaches to comply with *Code*-specified performance criteria. It is stipulated, however, that equivalency must be demonstrated by appropriate technical documentation. The evaluation and approval of such systems and approaches is the responsibility of the authority having jurisdiction.

[Exhibit 1.5](#) depicts the atrium at the Brown Palace Hotel in Denver, Colorado. The atrium was built as part of the original hotel in 1892. Building and life safety codes in the United States addressed atrium buildings for the first time in approximately 1980. An atrium constructed prior to 1980 might have utilized the equivalency concept to overcome what otherwise would

have been an unprotected vertical opening that could spread the effects of fire from floor to floor.

The *Code* contemplates the several forms of equivalency that follow.

**1. Code-specified alternative.** In some instances, the *Code* presents a written requirement and then provides an alternate method of obtaining the desired level of protection, usually via an exemption. For example, for new educational occupancies, [14.3.6](#) requires that interior corridors be constructed of 1-hour fire resistance-rated assemblies. However, [14.3.6\(2\)](#) allows the 1-hour rating requirement to be reduced to that of a nonrated smoke partition if the building is protected throughout by an approved, supervised automatic sprinkler system. Thus, the *Code* specifies that the combination of smoke partitions and sprinkler protection is the equivalent of 1-hour fire resistance-rated corridor walls for new educational occupancies.

**2. NFPA 101A equivalency methods.** NFPA 101A, *Guide on Alternative Approaches to Life Safety*,<sup>1</sup> provides a set of equivalency methods that can be used to assess equivalency for health care occupancies, detention and correctional occupancies, board and care occupancies, business occupancies, and educational occupancies. Each of the formalized equivalency methods in NFPA 101A is named a Fire Safety Evaluation System, or FSES. Each system awards high point values for providing a building with strong life safety and fire protection features and assesses low point values for unsafe conditions. Factors are weighted with respect to their impact on life safety principles. High point values are used to offset low point values. The completed evaluations are presented to the authority having jurisdiction for review and approval. Examples of FSESs performed on a sample health care occupancy building can be found in the *NFPA 101A Handbook — Guide on Alternative Approaches to Life Safety*.<sup>2</sup>

In addition to the fire safety evaluation systems, NFPA 101A contains a procedure for determining the evacuation capability for residents of existing residential board and care occupancies. Use of this method is also subject to the review and approval of the authority having jurisdiction. The requirements of [Chapter 33](#), applicable to existing residential board and care occupancies, vary depending on the evacuation capability of the residents and staff working together as a group. Examples of evacuation capability determination performed for residents of a sample residential board care occupancy can be found in the *NFPA 101A Handbook — Guide on Alternative Approaches to Life Safety*.

**3. More recent edition of the Code.** As explained in [A.1.4](#), future editions of the *Code* are considered refinements of earlier editions because they clarify intent with respect to the revised topics. Use of a newer edition in its entirety should be considered as equivalent to use of an earlier edition.

Caution must be exercised when applying the concept of equivalency via use of a newer edition. It is important to recognize that specific provisions are part of a carefully crafted set of

**Exhibit 1.5**

Atrium (Brown Palace Hotel, Denver, CO). (Courtesy of Brown Palace Hotel, Denver, CO)

requirements that result in a desired level of life safety. A revision to one portion of the *Code* might be a part of, or the result of, changes to other parts of the *Code*. Therefore, it would be inappropriate to refer only to a specific section of a more recent edition of the *Code* that reflects a less stringent requirement than previous editions without taking into account any associated provisions that may have become more stringent to compensate for that more relaxed provision.

It is not the intent of the *Code* to limit the user to the three specified forms of equivalency. It is the intent to allow emerging technology to be used to satisfy the prescribed performance requirements. Fire modeling (see the definition of *fire model* in 3.3.101) has developed to the stage that authorities having jurisdiction are routinely approving equivalency on the basis of such technology. Additionally, the results of fire tests and other documented forms of engineering analysis have prompted the approval of authorities having jurisdiction.

**1.4.1 Technical Documentation.** Technical documentation shall be submitted to the authority having jurisdiction to demonstrate equivalency.

**1.4.2 Approval.** The system, method, or device shall be approved for the intended purpose by the authority having jurisdiction.

**1.4.3\* Equivalent Compliance.** Alternative systems, methods, or devices approved as equivalent by the authority having jurisdiction shall be recognized as being in compliance with this *Code*.

**A.1.4.3** An equivalent method of protection provides an equal or greater level of safety. It is not a waiver or deletion of a *Code* requirement.

The prescriptive provisions of this *Code* provide specific requirements for broad classifications of buildings and structures. These requirements are stated in terms of fixed values, such as maximum travel distance, minimum fire resistance ratings, and minimum features of required systems, such as detection, alarm, suppression, and ventilation, and not in terms of overall building or system performance.

However, the equivalency clause in 1.4.3 permits the use of alternative systems, methods, or devices to meet the intent of the prescribed code provisions where approved as being equivalent. Through the rigor of a performance-based design, it can be demonstrated whether a building design is satisfactory and complies with the implicit or explicit intent of the applicable code requirement.

When employing the equivalency clause, it is important to clearly identify the prescriptive-based code provision being addressed (scope), to provide an interpretation of the intent of the provision (goals and objectives), to provide an alternative approach (proposed design), and to provide appropriate support for the suggested alternative (evaluation of proposed designs).

Performance resulting from proposed designs can be compared to the performance of the design features required by this *Code*. Using prescribed features as a baseline for comparison, it can then be demonstrated in the evaluation whether a proposed design offers the intended level of performance. A comparison of safety provided can be used as the basis for establishing equivalency.

Subsection 1.4.3 emphasizes that there is more than one way to achieve *Code* compliance. A building either follows the specification criteria, achieves equivalency, or meets the requirements that apply to a full performance-based design. Where the equivalency option is used and the authority having jurisdiction has judged the alternative approach to life safety as providing equivalency to the *Code* requirements, a building is considered to be *Code* compliant. Compliance through equivalency does not differ from compliance through strict adherence to the specification-based requirements; however, compliance through equivalency does differ from a waiver that permits continued use of a noncomplying building. The *Code* provisions do not recognize the concept of waivers, but instead require that a level of safety is provided that is equivalent to that required by the prescriptive-based provisions.

---

## 1.5 Units and Formulas

**1.5.1 SI Units.** Metric units of measurement in this *Code* are in accordance with the modernized metric system known as the International System of Units (SI).

**1.5.2 Primary Values.** The inch-pound value for a measurement, and the SI value given in parentheses, shall each be acceptable for use as primary units for satisfying the requirements of this *Code*.

In the *Code*, inch-pound values for measurements appear first, and metric (SI) values are given within parentheses, as permitted by the *NFPA Manual of Style for NFPA Technical Committee Documents*.<sup>3</sup> The 2003 edition of the *Code* experimented with presenting SI units first and following with inch-pound values within parentheses in an attempt to give the *Code* more international appeal. As a result, well-established criteria changed in format. For example, the requirement for new hospital and nursing home corridors to be a minimum of 8 ft (2440 mm) wide was changed to express that width as 2440 mm (96 in.). The average user could not readily comprehend the large inch specifications, which required the conversion of 96 in. to 8 ft. The experiment with the change in units failed. The 2006 edition returned the formatting to that used in earlier editions of the *Code*.

As permitted by 1.5.2, the inch-pound value and the SI value are each acceptable for use as primary values for satisfying

the requirements of this *Code*. The metric values are calculated by taking the inch-pound values, applying conversion factors, and rounding to a specified number of significant digits. Thus, the SI values might not represent the nominal dimensions to which products are manufactured for use in countries using SI units.

---

## 1.6 Enforcement

This *Code* shall be administered and enforced by the authority having jurisdiction designated by the governing authority.

NFPA publishes **Chapters 1** through **43** of the *Code* using mandatory language suitable for adoption for regulatory purposes. **Section 1.6** establishes the authority having jurisdiction (see definition in **3.2.2**) as the entity responsible for administering and enforcing the *Code*. The role of the AHJ is further defined in **4.6.1**.

## References Cited in Commentary

1. NFPA 101A, *Guide on Alternative Approaches to Life Safety*, 2013 edition, National Fire Protection Association, Quincy, MA. (Note: The 2013 edition of NFPA 101A is calibrated to measure equivalency against the requirements of the 2012 edition of the *Code*. The 2016 edition of NFPA 101A will measure equivalency against the requirements of the 2015 edition of the *Code*. NFPA 101A is published one year after its companion edition of the *Code*, since it is necessary to have the *Code* revisions finalized before calibrating the NFPA 101A fire safety evaluation systems.)
2. *NFPA 101A Handbook — Guide on Alternative Approaches to Life Safety*, 2013 edition, National Fire Protection Association, Quincy, MA. (Note: The 2013 Handbook is the first. It is expected that a 2016 edition will be published. See Reference 1 above.)

# Referenced Publications

## 2.1 General

The documents referenced in this chapter, or portions of such documents, are referenced within this *Code*, shall be considered part of the requirements of this *Code*, and the following shall also apply:

- (1)\* Documents referenced in this chapter, or portion of such documents, shall only be applicable to the extent called for within other chapters of this *Code*.
- (2) Where the requirements of a referenced code or standard differ from the requirements of this *Code*, the requirements of this *Code* shall govern.
- (3)\* Existing buildings or installations that do not comply with the provisions of the codes or standards referenced in this chapter shall be permitted to be continued in service, provided that the lack of conformity with these documents does not present a serious hazard to the occupants as determined by the authority having jurisdiction.

**A.2.1(1)** For example, NFPA 10, *Standard for Portable Fire Extinguishers*, is referenced in **Chapter 2**. This does not mean that all buildings must have portable fire extinguishers. Portable fire extinguishers are mandatory only to the extent called for elsewhere in the *Code*.

**A.2.1(3)** The Committee on Safety to Life recognizes that it is impractical to continually upgrade existing buildings or installations to comply with all the requirements of the referenced publications included in **Chapter 2**.

The provisions of **Section 2.1** deviate from the boilerplate text or template used at the beginning of **Chapter 2** of most NFPA codes and standards. The standard template did not provide the information needed for the user to understand to what degree the referenced publications are to be followed and whether it is intended that existing systems be upgraded to the requirements of the edition of the document cited. The revised provisions of **Section 2.1** include **2.1(3)**, which in earlier editions had been relegated to, and lost within, the general provisions of **Chapter 4**. All text relevant to mandatory referenced publications resides in one place at the beginning of **Chapter 2**.

**Chapter 2** lists mandatory referenced publications. It provides the full title and edition year for documents referenced mandatorily by other *Code* sections. The references interspersed throughout the *Code* might include only an identifier, for example NFPA 13, without providing a title. The *Code* user is presented

with a complete list of publications needed for effective use of the *Code*. The provisions of the publications that are mandated by the *Code* are also requirements in the same way, for example, that the provisions of **Chapter 7**, Means of Egress, are mandated. Regardless of whether a requirement actually resides within the *Code* or is mandatorily referenced and appears only in the referenced publication, the requirement must be met to achieve compliance with the *Code*. **Annex C** lists the nonmandatory referenced publications that appear in the advisory text of Annex A.

The reasons for locating all mandatory references in a single chapter are, first, to simplify use of the *Code* and, second, to make it easier for adopting jurisdictions to update the references in only one location rather than throughout the *Code*. The editions of the referenced publications listed in **Chapter 2** are legally referenced editions, unless the jurisdiction, when adopting the *Code*, has updated the list of codes and standards.

The *Life Safety Code* achieves its intended level of occupant safety by mandating the installation of various building features and systems. Where specific equipment and systems are required, their proper installation and maintenance are important. Rather than develop its own installation criteria, the *Code* mandates the use of expert documents. The referenced document becomes a legally enforceable part of NFPA 101.

The *Code* user is cautioned not to browse **Chapter 2** for purposes of identifying which documents must be used for complying with the *Code*. Instead, the user should locate the applicable *Code* provision that mandates the use of a particular publication in order to understand the extent to which the referenced publication must be followed.

The level of reference to a particular document varies. For example, although NFPA 72®, *National Fire Alarm and Signaling Code*,<sup>1</sup> permits numerous occupant notification measures, NFPA 101 might limit the options that can be used for an occupancy. **Paragraphs 14.3.4.3.1.3** and **15.3.4.3.1.3** permit positive alarm sequence notification for new and existing educational occupancies; however, rather than specifying the role of positive alarm sequence, those paragraphs refer to **9.6.3.4**. **Paragraph 9.6.3.4** points the user to NFPA 72 for the detailed criteria applicable to positive alarm sequence, provided that the occupancy chapter permits its use.

Another occupant notification method, the presignal system, as described in NFPA 72, is addressed by the *Code*. Once again, however, an occupancy chapter must permit the presignal system as detailed in **9.6.3.3**. A presignal system is not permitted for use in educational occupancies. Therefore, even though it is recognized in NFPA 72, this occupant notification

method is not permitted for schools. Thus, not all of the options offered by a referenced document can be used. The user of the Code must be aware of the reference and of any limitations or caveats on use of the referenced document.

NFPA 101, like other NFPA codes and standards, can mandate the use of a referenced document only if that document is an existing, ANSI-accredited, consensus-based code or standard. NFPA policy does not permit mandating the use of a referenced document that has not been developed under consensus procedures, nor does it permit reference to those documents developed by committees whose membership is not balanced with respect to user interests. A code or standard written by a committee dominated by an interest group has too great a potential for bias.

The documents listed in Chapter 2 are mandatory only to the extent called for in the Code. For example, the inclusion of NFPA 13, *Standard for the Installation of Sprinkler Systems*,<sup>2</sup> does not mean that all buildings must be sprinklered. Rather, where the Code requires buildings, other than small residential occupancies, to be sprinklered, NFPA 13 is to be used for sprinkler installation. See 9.7.1.1 as an example of Code language that mandatorily references the use of other NFPA documents.

Some of the referenced documents listed in Chapter 2 have very limited application. For example, NFPA 241, *Standard for Safeguarding Construction, Alteration, and Demolition Operations*,<sup>3</sup> is listed among the NFPA publications in Section 2.2. Its use is mandated only for construction and rehabilitation in health care occupancies and ambulatory health care occupancies. See 18.7.9.2, 19.7.9.2, 20.7.9.2, and 21.7.9.2.

The Code recognizes that existing installations are not required to be continuously upgraded as new editions of the referenced standards are adopted. This is specified in 2.1(3).

Section 2.2 was revised by a tentative interim amendment (TIA).

## 2.2\* NFPA Publications

National Fire Protection Association, 1 Batterymarch Park, Quincy, MA 02169-7471.

It is NFPA policy that the edition of the NFPA publications referenced be the most current at the time the Code is issued. The life safety technical committees do not have to act to update the edition of referenced NFPA publications. The updating occurs editorially by policy of the NFPA Standards Council.

The publications by organizations other than NFPA, listed in Section 2.3, carry an edition date adopted by the life safety technical committees via the normal revision process involving public inputs, first revisions, public comments, and second revisions. This means the technical committees must take deliberate action to adopt a specific edition of a publication by an

organization other than NFPA. This is done to ensure that the provisions of such documents, mandated for use with the Code, are appropriate.

NFPA 10, *Standard for Portable Fire Extinguishers*, 2013 edition.

NFPA 11, *Standard for Low-, Medium-, and High-Expansion Foam*, 2010 edition.

NFPA 12, *Standard on Carbon Dioxide Extinguishing Systems*, 2011 edition.

NFPA 12A, *Standard on Halon 1301 Fire Extinguishing Systems*, 2009 edition.

NFPA 13, *Standard for the Installation of Sprinkler Systems*, 2013 edition.

NFPA 13D, *Standard for the Installation of Sprinkler Systems in One- and Two-Family Dwellings and Manufactured Homes*, 2013 edition.

NFPA 13R, *Standard for the Installation of Sprinkler Systems in Low-Rise Residential Occupancies*, 2013 edition.

NFPA 14, *Standard for the Installation of Standpipe and Hose Systems*, 2013 edition.

NFPA 15, *Standard for Water Spray Fixed Systems for Fire Protection*, 2012 edition.

NFPA 16, *Standard for the Installation of Foam-Water Sprinkler and Foam-Water Spray Systems*, 2011 edition.

NFPA 17, *Standard for Dry Chemical Extinguishing Systems*, 2013 edition.

NFPA 17A, *Standard for Wet Chemical Extinguishing Systems*, 2013 edition.

NFPA 45, *Standard on Fire Protection for Laboratories Using Chemicals*, 2011 edition.

NFPA 54, *National Fuel Gas Code*, 2015 edition.

NFPA 58, *Liquefied Petroleum Gas Code*, 2014 edition.

NFPA 70®, *National Electrical Code*®, 2014 edition.

NFPA 72®, *National Fire Alarm and Signaling Code*, 2013 edition.

NFPA 80, *Standard for Fire Doors and Other Opening Protectives*, 2013 edition.

NFPA 82, *Standard on Incinerators and Waste and Linen Handling Systems and Equipment*, 2014 edition.

NFPA 88A, *Standard for Parking Structures*, 2015 edition.

NFPA 90A, *Standard for the Installation of Air-Conditioning and Ventilating Systems*, 2015 edition.

NFPA 90B, *Standard for the Installation of Warm Air Heating and Air-Conditioning Systems*, 2015 edition.

NFPA 91, *Standard for Exhaust Systems for Air Conveying of Vapors, Gases, Mists, and Noncombustible Particulate Solids*, 2010 edition.

NFPA 92, *Standard for Smoke Control Systems*, 2012 edition.

NFPA 96, *Standard for Ventilation Control and Fire Protection of Commercial Cooking Operations*, 2014 edition.

NFPA 99, *Health Care Facilities Code*, 2015 edition.

NFPA 101A, *Guide on Alternative Approaches to Life Safety*, 2013 edition.

NFPA 105, *Standard for Smoke Door Assemblies and Other Opening Protectives*, 2013 edition.

NFPA 110, *Standard for Emergency and Standby Power Systems*, 2013 edition.

NFPA 111, *Standard on Stored Electrical Energy Emergency and Standby Power Systems*, 2013 edition.

NFPA 160, *Standard for the Use of Flame Effects Before an Audience*, 2011 edition.

NFPA 170, *Standard for Fire Safety and Emergency Symbols*, 2012 edition.

NFPA 204, *Standard for Smoke and Heat Venting*, 2012 edition.

NFPA 211, *Standard for Chimneys, Fireplaces, Vents, and Solid Fuel-Burning Appliances*, 2013 edition.

NFPA 220, *Standard on Types of Building Construction*, 2015 edition.

NFPA 221, *Standard for High Challenge Fire Walls, Fire Walls, and Fire Barrier Walls*, 2015 edition.

NFPA 241, *Standard for Safeguarding Construction, Alteration, and Demolition Operations*, 2013 edition.

NFPA 252, *Standard Methods of Fire Tests of Door Assemblies*, 2012 edition.

NFPA 253, *Standard Method of Test for Critical Radiant Flux of Floor Covering Systems Using a Radiant Heat Energy Source*, 2011 edition.

NFPA 257, *Standard on Fire Test for Window and Glass Block Assemblies*, 2012 edition.

NFPA 259, *Standard Test Method for Potential Heat of Building Materials*, 2013 edition.

NFPA 260, *Standard Methods of Tests and Classification System for Cigarette Ignition Resistance of Components of Upholstered Furniture*, 2013 edition.

NFPA 261, *Standard Method of Test for Determining Resistance of Mock-Up Upholstered Furniture Material Assemblies to Ignition by Smoldering Cigarettes*, 2013 edition.

NFPA 265, *Standard Methods of Fire Tests for Evaluating Room Fire Growth Contribution of Textile or Expanded Vinyl Wall Coverings on Full Height Panels and Walls*, 2011 edition.

NFPA 286, *Standard Methods of Fire Tests for Evaluating Contribution of Wall and Ceiling Interior Finish to Room Fire Growth*, 2011 edition.

NFPA 288, *Standard Methods of Fire Tests of Horizontal Fire Door Assemblies Installed in Horizontal Fire Resistance-Rated Assemblies*, 2012 edition.

NFPA 289, *Standard Method of Fire Test for Individual Fuel Packages*, 2013 edition.

NFPA 400, *Hazardous Materials Code*, 2013 edition.

NFPA 415, *Standard on Airport Terminal Buildings, Fueling Ramp Drainage, and Loading Walkways*, 2013 edition.

NFPA 418, *Standard for Heliports*, 2011 edition.

NFPA 701, *Standard Methods of Fire Tests for Flame Propagation of Textiles and Films*, 2010 edition.

NFPA 703, *Standard for Fire Retardant-Treated Wood and Fire-Retardant Coatings for Building Materials*, 2015 edition.

NFPA 720, *Standard for the Installation of Carbon Monoxide (CO) Detection and Warning Equipment*, 2015 edition.

NFPA 731, *Standard for the Installation of Electronic Premises Security Systems*, 2015 edition.

NFPA 750, *Standard on Water Mist Fire Protection Systems*, 2015 edition.

NFPA 914, *Code for Fire Protection of Historic Structures*, 2010 edition.

NFPA 1126, *Standard for the Use of Pyrotechnics Before a Proximate Audience*, 2011 edition.

NFPA 2001, *Standard on Clean Agent Fire Extinguishing Systems*, 2012 edition.

**A.2.2** It is possible that governing authorities have adopted a code or standard other than one that is listed in **Chapter 2**. Where such is the case, and where a provision of a code or standard is referenced by this *Code* but the text of the requirement is not extracted into this *Code*, the code or standard adopted by the governing authority is permitted to be utilized where it is deemed by the authority having jurisdiction to adequately address the issue or condition of concern. Where the adopted code or standard does not address the issue, the requirement from the referenced code or standard should be applied by the authority having jurisdiction, unless the governing authority has established other procedures, policies, or guidelines. Where the text of a requirement is extracted from another NFPA code or standard and appears in this *Code*, it is the intent that the requirement be met as if it had originated in this *Code*, regardless of whether the governing authority has adopted the code or standard from which the text is extracted.

ASCE/SEI 7, *Minimum Design Loads for Buildings and Other Structures*, 2010.

An extract is a requirement taken from another NFPA code or standard. A reference in brackets [ ] following Code text indicates the source of the extracted material. As an aid to the user, the complete title and edition of the source documents for extracts in mandatory sections of the Code are given in Section 2.4, and those for extracts in informational annexes are given in Annex C. Extracted text may be edited for consistency and style and may include the revision of internal paragraph references and other references as appropriate, but it is otherwise technically consistent with that of the source document. For example, see 42.8.3.1.1.1 through 42.8.3.1.1.5, where the provisions for the protection of vertical openings in enclosed parking structures are extracted from NFPA 88A, *Standard for Parking Structures*.<sup>6</sup>

# Definitions

Anyone who has ever participated in a code-development process — whether it be NFPA's or that of another organization — knows of the many hours spent deliberating whether the language is clear and easily understood and whether it expresses the committee's intent. Establishing the requirements for a code is not an easy task. During committee meetings, the question is usually asked regarding whether everyone will understand the limits or application of a particular rule. Invariably, the same questions are asked about select words or terms.

When words or terms used in the *Code* fall outside of generally accepted meanings or dictionary definitions — or otherwise require a clarification — they are defined in [Chapter 3](#). When a word is not defined, the *Code* intends for the user to employ the dictionary definition — in this case, *Merriam-Webster's Collegiate Dictionary*.<sup>1</sup> See [Section 3.1](#).

For example, the word *exit* has numerous meanings in the dictionary. Included is the definition “goes off the stage,” used as a stage direction for a specified actor to leave the stage. Another definition includes the following three meanings:

1. “The act of going out or going away”
2. “Death”
3. “A passage” or “a way out”

To the layperson, “a passage” or “a way out” is probably what is understood when hearing the term *exit* used or seeing an exit sign. The NFPA 101 definition, however, is somewhat more detailed and is used to set limits on what actually constitutes an exit. The NFPA 101 definition in [3.3.83](#) reads as follows:

**Exit.** That portion of a means of egress that is separated from all other spaces of a building or structure by construction, location, or equipment as required to provide a protected way of travel to the exit discharge.

*Exit* is but one of the more than 270 terms defined in [Chapter 3](#) of the *Code*. The definitions for occupancy classifications (e.g., assembly occupancy, mercantile occupancy, industrial occupancy) appear in [Chapter 3](#), are presented alphabetically under the heading *Occupancy* (see [3.3.190](#)), and are repeated in their entirety in [Chapter 6](#), where they are arranged in the order in which the occupancy chapters are presented (see [6.1.2](#) through [6.1.13](#)) to assist the user of the *Code* in properly classifying an occupancy. The definitions for rehabilitation work categories (e.g., repair, renovation, modification, reconstruction) appear in [Chapter 3](#) — where they are interspersed alphabetically among unrelated terms — and in [Chapter 43](#), where they are presented in order of increasing complexity of rehabilitation

type (see [43.2.2.1](#)) for coordination with the order in which the requirements for the rehabilitation work categories are presented in the chapter.

Defined terms in NFPA documents should not contain requirements. To the extent possible, defined terms provide only the meaning of a term within the context of the *Code* requirements. Therefore, the terms *noncombustible (material)* and *limited-combustible (material)*, which formerly appeared in [Chapter 3](#) and included requirements, now appear in [4.6.13](#) and [4.6.14](#), respectively. The material addressing each term has been expanded into numbered paragraphs that contain criteria in excess of what should be contained within a defined term. See [3.3.171.2](#) for a cross-reference to [4.6.14](#) and [3.3.171.4](#) for a cross-reference to [4.6.13](#). The cross-references were added to direct the user, who might have become accustomed to finding the definitions for *limited-combustible (material)* and *noncombustible (material)* in [Chapter 3](#) of earlier editions, to the detailed criteria in [Chapter 4](#).

---

## 3.1 General

The definitions contained in this chapter shall apply to the terms used in this *Code*. Where terms are not defined in this chapter or within another chapter, they shall be defined using their ordinarily accepted meanings within the context in which they are used. *Merriam-Webster's Collegiate Dictionary*, 11th edition, shall be the source for the ordinarily accepted meaning.

---

## 3.2 NFPA Official Definitions

[Section 3.2](#), NFPA Official Definitions, contains NFPA definitions, for seven terms, that are not subject to change by the technical committees responsible for the *Code*. The official definitions are provided for terms that are common among the NFPA codes and standards and for which multiple definitions would confuse users. See [Section 3.3](#), General Definitions, for terms that are specifically defined for use with the provisions of this *Code*.

**3.2.1\* Approved.** Acceptable to the authority having jurisdiction.

**A.3.2.1 Approved.** The National Fire Protection Association does not approve, inspect, or certify any installations, procedures, equipment, or materials; nor does it approve or evaluate testing

laboratories. In determining the acceptability of installations, procedures, equipment, or materials, the authority having jurisdiction may base acceptance on compliance with NFPA or other appropriate standards. In the absence of such standards, said authority may require evidence of proper installation, procedure, or use. The authority having jurisdiction may also refer to the listings or labeling practices of an organization that is concerned with product evaluations and is thus in a position to determine compliance with appropriate standards for the current production of listed items.

**3.2.2\* Authority Having Jurisdiction (AHJ).** An organization, office, or individual responsible for enforcing the requirements of a code or standard, or for approving equipment, materials, an installation, or a procedure.

**A.3.2.2 Authority Having Jurisdiction (AHJ).** The phrase “authority having jurisdiction,” or its acronym AHJ, is used in NFPA documents in a broad manner, since jurisdictions and approval agencies vary, as do their responsibilities. Where public safety is primary, the authority having jurisdiction may be a federal, state, local, or other regional department or individual such as a fire chief; fire marshal; chief of a fire prevention bureau, labor department, or health department; building official; electrical inspector; or others having statutory authority. For insurance purposes, an insurance inspection department, rating bureau, or other insurance company representative may be the authority having jurisdiction. In many circumstances, the property owner or his or her designated agent assumes the role of the authority having jurisdiction; at government installations, the commanding officer or departmental official may be the authority having jurisdiction.

**3.2.3\* Code.** A standard that is an extensive compilation of provisions covering broad subject matter or that is suitable for adoption into law independently of other codes and standards.

**A.3.2.3 Code.** The decision to designate a standard as a “code” is based on such factors as the size and scope of the document, its intended use and form of adoption, and whether it contains substantial enforcement and administrative provisions.

**3.2.4 Labeled.** Equipment or materials to which has been attached a label, symbol, or other identifying mark of an organization that is acceptable to the authority having jurisdiction and concerned with product evaluation, that maintains periodic inspection of production of labeled equipment or materials, and by whose labeling the manufacturer indicates compliance with appropriate standards or performance in a specified manner.

**3.2.5\* Listed.** Equipment, materials, or services included in a list published by an organization that is acceptable to the authority having jurisdiction and concerned with evaluation of products or services, that maintains periodic inspection of production of listed equipment or materials or periodic evaluation of services,

and whose listing states that either the equipment, material, or service meets appropriate designated standards or has been tested and found suitable for a specified purpose.

**A.3.2.5 Listed.** The means for identifying listed equipment may vary for each organization concerned with product evaluation; some organizations do not recognize equipment as listed unless it is also labeled. The authority having jurisdiction should utilize the system employed by the listing organization to identify a listed product.

**3.2.6 Shall.** Indicates a mandatory requirement.

**3.2.7 Should.** Indicates a recommendation or that which is advised but not required.

---

## 3.3 General Definitions

During each revision cycle, the technical committees responsible for the *Code* work to reduce the number of definitions in [Section 3.3](#) that differ from the definitions identified as “preferred” terms in the *NFPA Glossary of Terms*.<sup>2</sup> A secondary definition that differs from the glossary’s preferred definition is permitted where the preferred definition does not meet the needs of the *Code*. For example, the Technical Committee on Means of Egress was asked to adopt the definition of *fire exit hardware* that is identified as preferred in the glossary and that appears in *NFPA 80, Standard for Fire Doors and Other Opening Protectives*.<sup>3</sup> The definition from NFPA 80 reads as follows:

**Fire Exit Hardware.** Labeled devices for swinging fire doors installed to facilitate safe egress of persons and generally consisting of a crossbar and various types of latch mechanisms that cannot hold the latch in a retracted locked position. [80, 2013]

The Technical Committee on Means of Egress acted to retain its secondary definition in *NFPA 101*, which reads as follows:

**Fire Exit Hardware.** A type of panic hardware that additionally provides fire protection where used as part of a fire door assembly.

In rejecting the definition that appears in *NFPA 80*, the committee explained that the proposed definition does not meet the needs of *NFPA 101*. For example, the preferred definition is too constricting in that it mentions a crossbar, but not a push pad; yet much of such hardware includes a push pad. *NFPA 101* has an adequate definition of *panic hardware*, and fire exit hardware is nothing more than a type of panic hardware that additionally provides fire protection where used as part of a fire door assembly.

**3.3.1 Accessible Area of Refuge.** See [3.3.22.1](#).

**3.3.2 Accessible Means of Egress.** See [3.3.172.1](#).

**3.3.3 Accessible Route.** A continuous unobstructed path that complies with this *Code* and ICC/ANSI A117.1, *American National Standard for Accessible and Usable Buildings and Facilities* (SAF-MEA).

**3.3.4\* Actuating Member or Bar.** The activating mechanism of a panic hardware or fire exit hardware device located on the egress side of a door. (SAF-MEA)

**A.3.3.4 Actuating Member or Bar.** The active surface of the actuating bar needs to be visually and physically distinct from the rest of the device. The actuating bar is also called a cross bar or push pad.

**Exhibit 3.1** illustrates the actuating member, in the form of a bar, for release of the door latch on a fire-rated door. The actuating member, or bar in this case, is *fire exit hardware* as it is listed for use on a fire-rated door assembly. See 3.3.135.1. **Exhibit 3.2** illustrates the actuating member, in the form of a push pad, for release of the door latch on a fire-rated door. The actuating member, or push pad in this case, is *fire exit hardware* as it, too, is listed for use on a fire-rated door assembly. Panic hardware is similar hardware that has not been tested and listed for use on a fire-rated door. The actuating member for panic hardware can take the form of a bar or a push pad. See 3.3.135.2.

**Exhibit 3.1**

*Latch release actuating member in the form of a bar.*

**3.3.5 Addition.** An increase in building area, aggregate floor area, building height, or number of stories of a structure. (SAF-FUN)

**3.3.6 Air Traffic Control Tower.** See 3.3.281.1.

**3.3.7 Aircraft Loading Walkway.** An aboveground device through which passengers move between a point in an airport terminal building and an aircraft. Included in this category are walkways that are essentially fixed and permanently placed, or

**Exhibit 3.2**

*Latch release actuating member in the form of a push pad.*

walkways that are essentially mobile in nature and that fold, telescope, or pivot from a fixed point at the airport terminal building. [415, 2013] (SAF-AXM)

**3.3.8 Air-Inflated Structure.** See 3.3.272.1.

**3.3.9 Airport Terminal Building.** See 3.3.36.1.

**3.3.10 Air-Supported Structure.** See 3.3.272.2.

**3.3.11\* Aisle Accessway.** The initial portion of an exit access that leads to an aisle. (SAF-AXM)

**A.3.3.11 Aisle Accessway.** *Aisle accessway* is the term used for the previously unnamed means of egress component leading to an aisle or other means of egress. For example, circulation space between parallel rows of seats having a width of 12 in. to 24 in. (305 mm to 610 mm) and a length not exceeding 100 ft (30 m) is an aisle accessway. Some of the circulation space between tables or seats in restaurants might be considered aisle accessway.

Depending on the width of aisle accessway, which is influenced by its length and expected utilization, the movement of a person through the aisle accessway might require others to change their individual speed of movement, alter their postures, move their chairs out of the way, or proceed ahead of the person.

The term *aisle accessway* in 3.3.11 would more accurately be shown if formatted to read as *Aisle Accessway (Assembly Occupancies)* in the same manner that the definition in 3.3.273.5 is shown as *Patient Care Suite (Health Care Occupancies)*. Aisle accessways occur in assembly seating areas. **Exhibit 3.3** illustrates an assembly seating area comprised of rows of chairs where the walking space in the seating rows constitutes the aisle

**Exhibit 3.3**

Walking space in the seating rows constitutes the aisle accessway.

accessway. The occupant moves from a seat to an aisle by traversing the aisle accessway. **Exhibit 3.4** illustrates an assembly seating area comprised of tables and chairs where the walking space behind the chairs constitutes the aisle accessway.

**Exhibit 3.4**

Walking space behind each chair constitutes the aisle accessway.

**3.3.12 Aisle Ramp.** See 3.3.221.1.

**3.3.13 Aisle Stair.** See 3.3.265.1.

**3.3.14 Alarm.**

**3.3.14.1 Single Station Alarm.** A detector comprising an assembly that incorporates a sensor, control components, and an alarm notification appliance in one unit operated from a

power source either located in the unit or obtained at the point of installation. [72, 2013] (SAF-BSF)

**3.3.14.2 Smoke Alarm.** A single or multiple-station alarm responsive to smoke. [72, 2013] (SAF-BSF)

**3.3.15 Alternative Calculation Procedure.** A calculation procedure that differs from the procedure originally employed by the design team but that provides predictions for the same variables of interest. (SAF-FUN)

**3.3.16 Ambulatory Health Care Occupancy.** See 3.3.190.1.

**3.3.17 Analysis.**

**3.3.17.1 Sensitivity Analysis.** An analysis performed to determine the degree to which a predicted output will vary given a specified change in an input parameter, usually in relation to models. (SAF-FUN)

**3.3.17.2 Uncertainty Analysis.** An analysis performed to determine the degree to which a predicted value will vary. (SAF-FUN)

**3.3.18 Anchor Building.** See 3.3.36.2.

**3.3.19 Apartment Building.** See 3.3.36.3.

**3.3.20 Approved Existing.** See 3.3.81.1.

**3.3.21 Area.**

**3.3.21.1 Detention and Correctional Residential Housing Area.** Sleeping areas and any contiguous day room, group activity space, or other common space for customary access of residents. (SAF-DET)

**3.3.21.2 Floor Area.**

**3.3.21.2.1\* Gross Floor Area.** The floor area within the inside perimeter of the outside walls of the building under consideration with no deductions for hallways, stairs, closets, thickness of interior walls, columns, elevator and building services shafts, or other features, but excluding floor openings associated with atriums and communicating spaces. (SAF-MEA)

**A.3.3.21.2.1 Gross Floor Area.** Where the term *floor area* is used, it should be understood to be gross floor area, unless otherwise specified.

The definition of the term *gross floor area* was revised for the 2015 edition of the *Code* to clarify that large vertical openings, such as atria and other convenience openings (see 8.6.6, 8.6.7, and 8.6.9), where occupants cannot walk because there is no floor, are permitted to be excluded from the gross area calculation. It is not the intent to permit the space occupied by stairwells, elevator shafts, or HVAC shafts to be omitted from the gross area calculation.

**3.3.21.2.2 Net Floor Area.** The floor area within the inside perimeter of the outside walls, or the outside walls and fire

walls of a building, or outside and/or inside walls that bound an occupancy or incidental use area requiring the occupant load to be calculated using net floor area under consideration with deductions for hallways, stairs, closets, thickness of interior walls, columns, or other features. (SAF-MEA)

The definition of the term *net floor area* was revised for the 2015 edition of the *Code* to clarify that net area does not always have to be calculated for an entire floor or fire compartment. For example, a conference room within a tenant office space is permitted to have its net floor area calculated for purposes of assigning an occupant load to it as an assembly use.

**3.3.21.3 Gross Leasable Area.** Fifty percent of major tenant areas, and 100 percent of all other floor areas designated for tenant occupancy and exclusive use, including storage areas. The area of tenant occupancy is measured from the centerlines of joint partitions to the outside of the tenant walls. (SAF-MER)

**3.3.21.4\* Hazardous Area.** An area of a structure or building that poses a degree of hazard greater than that normal to the general occupancy of the building or structure. (SAF-FIR)

**A.3.3.21.4 Hazardous Area.** Hazardous areas include areas for the storage or use of combustibles or flammables; toxic, noxious, or corrosive materials; or heat-producing appliances.

**3.3.21.5 Living Area.** Any normally occupiable space in a residential occupancy, other than sleeping rooms or rooms that are intended for combination sleeping/living, bathrooms, toilet compartments, kitchens, closets, halls, storage or utility spaces, and similar areas. (SAF-RES)

**3.3.21.6\* Normally Unoccupied Building Service Equipment Support Area.** A building service equipment support area in which people are not expected to be present on a regular basis. (SAF-MEA)

**A.3.3.21.6 Normally Unoccupied Building Service Equipment Support Area.** Normally unoccupied building service support areas are often found in attics, crawl spaces, chases, and interstitial areas where the space is vacant or intended exclusively for routing ductwork, cables, conduits, piping, and similar services and is rarely accessed. In such spaces, it is often difficult or impossible to fully comply with the egress requirements of [Chapter 7](#). Where portions of such spaces are routinely visited for storage, maintenance, testing, or inspection, that portion is excluded from this definition, but the remainder of the space might be considered a normally unoccupied building service equipment support area. Storage and fuel-fired equipment would not be expected to be permitted in these locations. Roofs are not considered to be normally unoccupied building service equipment support areas.

The definition of the term *normally unoccupied building service equipment support area* was created to support the requirements of [Section 7.13](#).

**3.3.21.7 Occupiable Area.** An area of a facility occupied by people on a regular basis. (SAF-FUN)

**3.3.21.8 Rehabilitation Work Area.** That portion of a building affected by any renovation, modification, or reconstruction work as initially intended by the owner, and indicated as such in the permit, but excluding other portions of the building where incidental work entailed by the intended work must be performed, and excluding portions of the building where work not initially intended by the owner is specifically required. (SAF-FUN)

**3.3.22\* Area of Refuge.** An area that is either (1) a story in a building where the building is protected throughout by an approved, supervised automatic sprinkler system and has not less than two accessible rooms or spaces separated from each other by smoke-resisting partitions; or (2) a space located in a path of travel leading to a public way that is protected from the effects of fire, either by means of separation from other spaces in the same building or by virtue of location, thereby permitting a delay in egress travel from any level. (SAF-MEA)

**A.3.3.22 Area of Refuge.** An area of refuge has a temporary use during egress. It generally serves as a staging area that provides relative safety to its occupants while potential emergencies are assessed, decisions are made, and mitigating activities are begun. Taking refuge within such an area is, thus, a stage of the total egress process, a stage between egress from the immediately threatened area and egress to a public way.

An area of refuge might be another building connected by a bridge or balcony, a compartment of a subdivided story, an elevator lobby, or an enlarged story-level exit stair landing. An area of refuge is accessible by means of horizontal travel or, as a minimum, via an accessible route meeting the requirements of ICC/ANSI A117.1, *American National Standard for Accessible and Usable Buildings and Facilities*.

This *Code* recognizes any floor in a building protected throughout by an approved, supervised automatic sprinkler system as an area of refuge. This recognition acknowledges the ability of a properly designed and functioning automatic sprinkler system to control a fire at its point of origin and to limit the production of toxic products to a level that is not life threatening.

The requirement for separated rooms or spaces can be met on an otherwise undivided floor by enclosing the elevator lobby with ordinary glass or other simple enclosing partitions that are smoke resisting.

For some occupancies, one accessible room or space is permitted.

The definition of the term *area of refuge* treads closely to containing requirements — a subject addressed in the commentary following the title of this chapter. Numerous other requirements for areas of refuge appear in [7.2.12](#). U.S. Government groups such as the General Services Administration make extensive use of the area of refuge provisions of this *Code*, but refer to the

Exhibit 3.5

Sign directing occupants to area of rescue assistance.

feature as an area of rescue assistance. The term *area of rescue assistance* helps to assure occupants that help is on the way during a fire emergency. Exhibit 3.5 illustrates a sign directing occupants to an area of rescue assistance.

**3.3.22.1 Accessible Area of Refuge.** An area of refuge that complies with the accessible route requirements of ICC/ANSI A117.1, *American National Standard for Accessible and Usable Buildings and Facilities*. (SAF-MEA).

### 3.3.23 Assembly.

**3.3.23.1 Door Assembly.** Any combination of a door, frame, hardware, and other accessories that is placed in an opening in a wall that is intended primarily for access or for human entrance or exit. [252, 2012] (SAF-MEA)

Exhibit 3.6 illustrates a door assembly. Note that the door assembly pictured includes the door frame, door leaf, vision panel, hinges, self-closing device, latch, and latch release in the form of panic hardware or fire exit hardware.

**3.3.23.1.1 Fire Door Assembly.** Any combination of a fire door, a frame, hardware, and other accessories that together provide a specific degree of fire protection to the opening. [80, 2012] (SAF-FIR)

Exhibit 3.7 illustrates a listing label affixed to the stile edge of the door leaf of a fire door assembly.

**3.3.23.1.1.1 Horizontal Fire Door Assembly.** A combination of a fire door, a frame, hardware, and other accessories installed in a horizontal plane, which together provide a specific degree of fire protection to a through-opening in a fire resistance-rated floor or roof. [288, 2012] (SAF-FIR)

**3.3.23.2 Fire Window Assembly.** A window or glass block assembly having a fire protection rating. [80, 2013] (SAF-FIR)

Exhibit 3.6

Door assembly.

Exhibit 3.7

Listing label affixed to door leaf of a fire door assembly.

**3.3.24 Assembly Occupancy.** See 3.3.190.2.

**3.3.25 Assisted Mechanical Type Parking Structure.** See 3.3.272.7.1.

### 3.3.26 Atmosphere.

**3.3.26.1 Common Atmosphere.** The atmosphere that exists between rooms, spaces, or areas within a building that are not separated by an approved smoke barrier. (SAF-END)

**3.3.26.2 Separate Atmosphere.** The atmosphere that exists between rooms, spaces, or areas that are separated by an approved smoke barrier. (SAF-END)

**3.3.27\* Atrium.** A large-volume space created by a floor opening or series of floor openings connecting two or more stories that is covered at the top of the series of openings and is used for purposes other than an enclosed stairway; an elevator hoistway; an escalator opening; or as a utility shaft used for plumbing, electrical, air-conditioning, or communications facilities. (SAF-FIR)

**A.3.3.27 Atrium.** As defined in NFPA 92, *Standard for Smoke Control Systems*, a large-volume space is an unpartitioned space, generally two or more stories high, within which smoke from a fire either in the space or in a communicating space can move and accumulate without restriction. Atria and covered malls are examples of large-volume spaces.

**Exhibit 3.8** illustrates an atrium in a high-rise hotel building.

**3.3.28\* Attic.** The space located between the ceiling of a story and the roof directly above that habitable story. (SAF-FUN)

**A.3.3.28 Attic.** The attic space might be used for storage. The concealed rafter space between the ceiling membrane and the

roof sheathing that are attached to the rafters is not considered an attic.

**3.3.29 Automated Type Parking Structure.** See 3.3.272.7.2.

**3.3.30 Automatic.** Capable of performing a function without the necessity of human intervention. (SAF-FUN)

### 3.3.31 Barrier.

**3.3.31.1\* Fire Barrier.** A continuous membrane or a membrane with discontinuities created by protected openings with a specified fire protection rating, where such membrane is designed and constructed with a specified fire resistance rating to limit the spread of fire. (SAF-FIR)

**A.3.3.31.1 Fire Barrier.** A fire barrier, such as a wall or floor assembly, might be aligned vertically or horizontally. Although the continuity of a fire barrier will often limit the transfer of smoke, it should not be confused with either a smoke barrier or a smoke partition.

**3.3.31.2\* Smoke Barrier.** A continuous membrane, or a membrane with discontinuities created by protected openings, where such membrane is designed and constructed to restrict the movement of smoke. (SAF-FIR)

**A.3.3.31.2 Smoke Barrier.** A smoke barrier might be vertically or horizontally aligned, such as a wall, floor, or ceiling assembly. A smoke barrier might or might not have a fire resistance rating. Application of smoke barrier criteria where required elsewhere in the *Code* should be in accordance with Section 8.3.

**Exhibit 3.9** illustrates the above-ceiling space at a smoke barrier in a hospital.

**Exhibit 3.8**

Atrium in a high-rise hotel building.

**Exhibit 3.9**

Above-ceiling space at a smoke barrier in a hospital.

**3.3.31.3\* Thermal Barrier.** A material that limits the average temperature rise of an unexposed surface to not more than 250°F (139°C) for a specified fire exposure complying with the standard time-temperature curve of ASTM E 119, *Standard Test Methods for Fire Tests of Building Construction and Materials*, or ANSI/UL 263, *Standard for Fire Tests of Building Construction and Materials*. (SAF-BCF).

**A.3.3.31.3 Thermal Barrier.** Finish ratings, as published in the *UL Fire Resistance Directory*, are one way of determining thermal barrier. A test method was developed in order to assess whether a material, product, or assembly constitutes a thermal barrier (see NFPA 275). It requires thermal barriers to meet both a test for fire resistance (temperature transmission test), which limits temperature rise on the unexposed side, and a test for reaction-to-fire (integrity fire test), intended to demonstrate that the material can prevent or delay ignition of the material on the unexposed side. The reaction to fire test is one of the following: NFPA 286, FM 4880, ANSI/UL 1040, or ANSI/UL 1715.

**3.3.32 Basement.** Any story of a building wholly or partly below grade plane that is not considered the first story above grade plane. (See also [3.3.126.1](#), *First Story Above Grade Plane*.) (SAF-FUN)

**3.3.33\* Birth Center.** A facility in which low-risk births are expected following normal, uncomplicated pregnancies, and in which professional midwifery care is provided to women during pregnancy, birth, and postpartum. (SAF-MER)

**A.3.3.33 Birth Center.** A birth center is a low-volume service for healthy, childbearing women, and their families, who are capable of ambulation in the event of fire or fire-threatening events. Birth center mothers and babies have minimal analgesia, receive no general or regional anesthesia, and are capable of ambulation, even in second-stage labor.

**3.3.34 Bleachers.** A grandstand in which the seats are not provided with backrests. (SAF-AXM)

**3.3.35 Board and Care.** See [3.3.190.12](#), Residential Board and Care Occupancy.

**3.3.36\* Building.** Any structure used or intended for supporting or sheltering any use or occupancy. (SAF-FUN)

**A.3.3.36 Building.** The term *building* is to be understood as if followed by the words *or portions thereof*. (See also *Structure*, [A.3.3.272](#).)

**3.3.36.1 Airport Terminal Building.** A structure used primarily for air passenger enplaning or deplaning, including ticket sales, flight information, baggage handling, and other necessary functions in connection with air transport operations. This term includes any extensions and satellite buildings used for passenger handling or aircraft flight service functions. Aircraft loading walkways and “mobile lounges” are excluded. [415, 2008] (SAF-AXM)

**3.3.36.2 Anchor Building.** A building housing any occupancy having low or ordinary hazard contents and having direct access to a mall building, but having all required means of egress independent of the mall. (SAF-MER)

**3.3.36.3\* Apartment Building.** A building or portion thereof containing three or more dwelling units with independent cooking and bathroom facilities. (SAF-RES)

**A.3.3.36.3 Apartment Building.** The *Code* specifies that, wherever there are three or more living units in a building, the building is considered an apartment building and is required to comply with either [Chapter 30](#) or [Chapter 31](#), as appropriate. Townhouse units are considered to be apartment buildings if there are three or more units in the building. The type of wall required between units in order to consider them to be separate buildings is normally established by the authority having jurisdiction. If the units are separated by a wall of sufficient fire resistance and structural integrity to be considered as separate buildings, then the provisions of [Chapter 24](#) apply to each townhouse. Condominium status is a form of ownership, not occupancy; for example, there are condominium warehouses, condominium apartments, and condominium offices.

**3.3.36.4 Bulk Merchandising Retail Building.** A building in which the sales area includes the storage of combustible materials on pallets, in solid piles, or in racks in excess of 12 ft (3660 mm) in storage height. (SAF-MER)

**3.3.36.5\* Existing Building.** A building erected or officially authorized prior to the effective date of the adoption of this edition of the *Code* by the agency or jurisdiction. (SAF-FUN)

**A.3.3.36.5 Existing Building.** With respect to judging whether a building should be considered existing, the deciding factor is not when the building was designed or when construction started but, rather, the date plans were approved for construction by the appropriate authority having jurisdiction.

**3.3.36.6\* Flexible Plan and Open Plan Educational or Day-Care Building.** A building or portion of a building designed for multiple teaching stations. (SAF-END)

**A.3.3.36.6 Flexible Plan and Open Plan Educational or Day-Care Building.** Flexible plan buildings have movable corridor walls and movable partitions of full-height construction with doors leading from rooms to corridors. Open plan buildings have rooms and corridors delineated by tables, chairs, desks, bookcases, counters, low-height partitions, or similar furnishings. It is the intent that low-height partitions not exceed 60 in. (1525 mm).

**3.3.36.7\* High-Rise Building.** A building where the floor of an occupiable story is greater than 75 ft (23 m) above the lowest level of fire department vehicle access. (SAF-FUN)

**A.3.3.36.7 High-Rise Building.** It is the intent of this definition that, in determining the level from which the highest

occupiable floor is to be measured, the enforcing agency should exercise reasonable judgment, including consideration of overall accessibility to the building by fire department personnel and vehicular equipment. Where a building is situated on a sloping terrain and there is building access on more than one level, the enforcing agency might select the level that provides the most logical and adequate fire department access.

**Exhibit 3.10** depicts high-rise buildings. The older concrete building in the foreground is 12 stories in height and also constitutes a high-rise building.

**Exhibit 3.10**

*High-rise buildings.*

**3.3.36.8\* Historic Building.** A building or facility deemed to have historical, architectural, or cultural significance by a local, regional, or national jurisdiction. (SAF-FUN)

**A.3.3.36.8 Historic Building.** Designation for a historic building might be in an official national, regional, or local historic register, listing, or inventory.

**Exhibit 3.11** depicts a historic building. In addition to being old, the building has architectural and cultural significance in the jurisdiction in which it is located.

**3.3.36.9\* Mall Building.** A single building enclosing a number of tenants and occupancies wherein two or more tenants have a main entrance into one or more malls. For the purpose of this *Code*, anchor buildings shall not be considered as a part of the mall building. (SAF-MER)

**Exhibit 3.11**

*A historic building.*

**A.3.3.36.9 Mall Building.** A mall building might enclose one or more uses, such as retail and wholesale stores, drinking and dining establishments, entertainment and amusement facilities, transportation facilities, offices, and other similar uses.

**3.3.36.10\* Special Amusement Building.** A building that is temporary, permanent, or mobile and contains a device or system that conveys passengers or provides a walkway along, around, or over a course in any direction as a form of amusement arranged so that the egress path is not readily apparent due to visual or audio distractions or an intentionally confounded egress path, or is not readily available due to the mode of conveyance through the building or structure. (SAF-AXM)

**A.3.3.36.10 Special Amusement Building.** Special amusement buildings include amusements such as a haunted house, a roller coaster-type ride within a building, a multilevel play structure within a building, a submarine ride, and similar amusements where the occupants are not in the open air.

**3.3.37\* Building Code.** The building code enforced by the jurisdiction or agency enforcing this *Code*. (SAF-FUN)

**A.3.3.37 Building Code.** Where no building code has been adopted, *NFPA 5000, Building Construction and Safety Code*, should be used where the building code is referenced in this *Code*.

The definition of the term *building code* addresses a building code in a generic sense in recognition of the fact that one common building code is not used in all jurisdictions that use this *Code*. For an example of the use of the term *building code* within the requirements of this *Code*, see 10.2.3.1.

**3.3.38 Bulk Merchandising Retail Building.** See 3.3.36.4.

**3.3.39 Business Occupancy.** See 3.3.190.3.

**3.3.40 Categories of Rehabilitation Work.** The nature and extent of rehabilitation work undertaken in an existing building. (SAF-FUN)

**3.3.41\* Cellular or Foamed Plastic.** A heterogeneous system comprised of not less than two phases, one of which is a continuous, polymeric, organic material, and the second of which is deliberately introduced for the purpose of distributing gas in voids throughout the material. (SAF-INT)

**A.3.3.41 Cellular or Foamed Plastic.** Cellular or foamed plastic might contain foamed and unfoamed polymeric or monomeric precursors (prepolymer, if used), plasticizers, fillers, extenders, catalysts, blowing agents, colorants, stabilizers, lubricants, surfactants, pigments, reaction control agents, processing aids, and flame retardants.

**3.3.42 Change of Occupancy Classification.** The change in the occupancy classification of a structure or portion of a structure. (SAF-FUN)

**3.3.43 Change of Use.** A change in the purpose or level of activity within a structure that involves a change in application of the requirements of the *Code* (SAF-FUN).

**3.3.44 Combustible (Material).** See 3.3.171.1.

**3.3.45 Combustion.** A chemical process of oxidation that occurs at a rate fast enough to produce heat and usually light in the form of either a glow or flame. (SAF-FUN)

**3.3.46 Common Atmosphere.** See 3.3.26.1.

**3.3.47\* Common Path of Travel.** The portion of exit access that must be traversed before two separate and distinct paths of travel to two exits are available. (SAF-MEA)

**A.3.3.47 Common Path of Travel.** Common path of travel is measured in the same manner as travel distance but terminates at that point where two separate and distinct routes become available. Paths that merge are common paths of travel.

**3.3.48 Compartment.**

**3.3.48.1\* Fire Compartment.** A space within a building that is enclosed by fire barriers on all sides, including the top and bottom. (SAF-FIR)

**A.3.3.48.1 Fire Compartment.** Additional fire compartment information is contained in 8.2.2.

In the provisions for fire compartments utilizing the outside walls of a building, it is not intended that the outside wall be specifically fire resistance rated, unless required by other standards. Likewise, it is not intended that outside windows or doors be protected, unless specifically required for exposure protection by another section of this *Code* or by other standards.

**3.3.48.2\* Smoke Compartment.** A space within a building enclosed by smoke barriers on all sides, including the top and bottom. (SAF-FIR)

**A.3.3.48.2 Smoke Compartment.** Where smoke compartments using the outside walls or the roof of a building are provided, it is not intended that outside walls or roofs, or any openings therein, be capable of resisting the passage of smoke. Application of smoke compartment criteria where required elsewhere in the *Code* should be in accordance with Section 8.5.

The definition of Consumer Fireworks, 1.4G was deleted by a tentative interim amendment (TIA).

**3.3.49 Contents and Furnishings.** Any movable objects in a building that normally are secured or otherwise put in place for functional reasons, excluding (1) parts of the internal structure of the building, and (2) any items meeting the definition of interior finish. (SAF-INT)

**3.3.50 Court.** An open, uncovered, unoccupied space, unobstructed to the sky, bounded on three or more sides by exterior building walls. (SAF-MEA)

**3.3.50.1 Enclosed Court.** A court bounded on all sides by the exterior walls of a building or by the exterior walls and lot lines on which walls are permitted. (SAF-MEA)

**3.3.50.2 Food Court.** A public seating area located in a mall that serves adjacent food preparation tenant spaces. (SAF-MER)

Exhibit 3.12 illustrates a food court in a mall.

**3.3.51\* Critical Radiant Flux.** The level of incident radiant heat energy in units of  $W/cm^2$  on a floor-covering system at the most distant flameout point. (SAF-INT)

**A.3.3.51 Critical Radiant Flux.** Critical radiant flux is the property determined by the test procedure of NFPA 253, *Standard Method of Test for Critical Radiant Flux of Floor Covering Systems Using a Radiant Heat Energy Source*. The unit of measurement of critical radiant flux is watts per square centimeter ( $W/cm^2$ ).

**3.3.52 Data Conversion.** The process of developing the input data set for the assessment method of choice. (SAF-FUN)

**3.3.53 Day-Care Home.** See 3.3.142.1.

Exhibit 3.12

Food court in a mall.

**3.3.54 Day-Care Occupancy.** See 3.3.190.4.

**3.3.55 Deep-Fat Frying.** A cooking method that involves fully immersing food in hot oil. (SAF-HEA)

The definition of the term *deep-fat frying* is new to the 2015 edition of the Code. The term is used in describing a prohibited use within kitchens that are open to corridors in health care occupancies. See 18.3.2.5.3 and 19.3.2.5.3.

**3.3.56 Design Fire Scenario.** See 3.3.105.1.

**3.3.57 Design Specification.** See 3.3.262.1.

**3.3.58 Design Team.** A group of stakeholders including, but not limited to, representatives of the architect, client, and any pertinent engineers and other designers. (SAF-FUN)

**3.3.59 Detention and Correctional Occupancy.** See 3.3.190.5.

**3.3.60 Detention and Correctional Residential Housing Area.** See 3.3.21.1.

**3.3.61 Device.**

**3.3.61.1\* Emergency Stair Travel Device.** Device designed and constructed to facilitate travel over interior floor surfaces, interior and exterior stairs, and exterior accessible pathways. (SAF-MEA)

**A.3.3.61.1 Emergency Stair Travel Device.** An emergency stair travel device should be designed, constructed, and operated in accordance with ANSI/RESNA ED-1, *Emergency Stair Travel Devices Used by Individuals with Disabilities*. The device typically requires the assistance of a trained operator.

Exhibit 3.13 illustrates an emergency stair travel device in an exit stair enclosure at NFPA headquarters.

Exhibit 3.13

Emergency stair travel device.

**3.3.61.2 Multiple-Station Alarm Device.** Two or more single-station alarm devices that can be interconnected so that actuation of one causes all integral or separate audible alarms to operate; or one single-station alarm device having connections to other detectors or to a manual fire alarm box. [72, 2013] (SAF-BSF)

**3.3.62 Door.**

**3.3.62.1 Elevator Lobby Door.** A door between an elevator lobby and another building space other than the elevator shaft. (SAF-MEA)

**3.3.62.2 Fire Door.** The door component of a fire door assembly. (SAF-FIR)

**3.3.63 Door Assembly.** See 3.3.23.1.

**3.3.64\* Dormitory.** A building or a space in a building in which group sleeping accommodations are provided for more than 16 persons who are not members of the same family in one room, or a series of closely associated rooms, under joint occupancy and single management, with or without meals, but without individual cooking facilities. (SAF-RES)

**A.3.3.64 Dormitory.** Rooms within dormitories intended for the use of individuals for combined living and sleeping purposes are guest rooms or guest suites. Examples of dormitories are college dormitories, fraternity and sorority houses, and military barracks.

**3.3.65 Draft Stop.** A continuous membrane used to subdivide a concealed space to resist the passage of smoke and heat. (SAF-FIR)

**3.3.66\* Dwelling Unit.** One or more rooms arranged for complete, independent housekeeping purposes with space for eating, living, and sleeping; facilities for cooking; and provisions for sanitation. (SAF-RES)

**A.3.3.66 Dwelling Unit.** It is not the intent of the *Code* that the list of spaces in the definition of the term *dwelling unit* in 3.3.66 is to be all inclusive. It is the intent of the *Code* that the list of spaces is a minimal set of criteria that must be provided to be considered a dwelling unit, and, therefore, the dwelling unit can contain other spaces that are typical to a single-family dwelling.

**3.3.66.1\* One- and Two-Family Dwelling Unit.** A building that contains not more than two dwelling units with independent cooking and bathroom facilities. (SAF-RES)

**A.3.3.66.1 One- and Two-Family Dwelling Unit.** The application statement of 24.1.1.1 limits each dwelling unit to being “occupied by members of a single family with not more than three outsiders.” The *Code* does not define the term *family*. The definition of family is subject to federal, state, and local regulations and might not be restricted to a person or a couple (two people) and their children. The following examples aid in differentiating between a single-family dwelling and a lodging or rooming house:

- (1) An individual or a couple (two people) who rent a house from a landlord and then sublease space for up to three individuals should be considered a family renting to a maximum of three outsiders, and the house should be regulated as a single-family dwelling in accordance with [Chapter 24](#).
- (2) A house rented from a landlord by an individual or a couple (two people) in which space is subleased to 4 or more individuals, but not more than 16, should be considered and regulated as a lodging or rooming house in accordance with [Chapter 26](#).
- (3) A residential building that is occupied by 4 or more individuals, but not more than 16, each renting from a landlord, without separate cooking facilities, should be considered and regulated as a lodging or rooming house in accordance with [Chapter 26](#).

**3.3.66.2 One-Family Dwelling Unit.** A building that consists solely of one dwelling unit with independent cooking and bathroom facilities. (SAF-RES)

**3.3.66.3 Two-Family Dwelling Unit.** A building that consists solely of two dwelling units with independent cooking and bathroom facilities. (SAF-RES)

**3.3.67 Educational Occupancy.** See [3.3.190.6](#).

**3.3.68\* Electroluminescent.** Refers to a light-emitting capacitor in which alternating current excites phosphor atoms placed between electrically conductive surfaces and produces light. (SAF-MEA)

**A.3.3.68 Electroluminescent.** This light source is typically contained inside the device.

**3.3.69 Elevator Evacuation System.** See [3.3.274.1](#).

**3.3.70 Elevator Lobby.** A landing from which occupants directly enter an elevator car(s) and into which occupants directly enter upon leaving an elevator car(s). (SAF-MEA)

**3.3.71 Elevator Lobby Door.** See [3.3.62.1](#).

**3.3.72 Emergency Stair Travel Device.** See [3.3.61.1](#).

**3.3.73 Enclosed Court.** See [3.3.50.1](#).

**3.3.74 Enclosed Parking Structure.** See [3.3.272.7.3](#).

**3.3.75 Equipment or Fixture.** Any plumbing, heating, electrical, ventilating, air-conditioning, refrigerating, and fire protection equipment; and elevators, dumbwaiters, escalators, boilers, pressure vessels, or other mechanical facilities or installations that are related to building services. (SAF-FUN)

**3.3.76 Equivalency.** An alternative means of providing an equal or greater degree of safety than that afforded by strict conformance to prescribed codes and standards. (SAF-FUN)

**3.3.77 Evacuation.** The withdrawal of occupants from a building. [72, 2013] (SAF-BSF)

**3.3.78\* Evacuation Capability.** The ability of occupants, residents, and staff as a group either to evacuate a building or to relocate from the point of occupancy to a point of safety.

**A.3.3.78 Evacuation Capability.** The evacuation capability of the residents and staff is a function of both the ability of the residents to evacuate and the assistance provided by the staff. It is intended that the evacuation capability be determined by the procedure acceptable to the authority having jurisdiction. It is also intended that the timing of drills, the rating of residents, and similar actions related to determining the evacuation capability be performed by persons approved by or acceptable to the authority having jurisdiction. The evacuation capability can be determined by the use of the definitions in [3.3.78](#), the application of NFPA 101A, *Guide on Alternative Approaches to Life Safety*, [Chapter 6](#), or a program of drills (timed).

Evacuation does not include the relocation of occupants within a building.

Where drills are used in determining evacuation capability, it is suggested that the facility conduct and record fire drills six times per year on a bimonthly basis, with a minimum of two drills conducted during the night when residents are sleeping,

and that the facility conduct the drills in consultation with the authority having jurisdiction. Records should indicate the time taken to reach a point of safety, date and time of day, location of simulated fire origin, escape paths used, and comments relating to residents who resisted or failed to participate in the drills.

Translation of drill times to evacuation capability is determined as follows:

- (1) 3 minutes or less — prompt
- (2) Over 3 minutes, but not in excess of 13 minutes— slow
- (3) More than 13 minutes — impractical

Evacuation capability, in all cases, is based on the time of day or night when evacuation of the facility would be most difficult, such as when residents are sleeping or fewer staff are present.

Evacuation capability determination is considered slow if the following conditions are met:

- (1) All residents are able to travel to centralized dining facilities without continuous staff assistance.
- (2) There is continuous staffing whenever there are residents in the facility.

**3.3.78.1 Impractical Evacuation Capability.** The inability of a group to reliably move to a point of safety in a timely manner. (SAF-BCF)

**3.3.78.2 Prompt Evacuation Capability.** The ability of a group to move reliably to a point of safety in a timely manner that is equivalent to the capacity of a household in the general population. (SAF-BCF)

**3.3.78.3 Slow Evacuation Capability.** The ability of a group to move reliably to a point of safety in a timely manner, but not as rapidly as members of a household in the general population. (SAF-BCF)

**3.3.79 Exhibit.** A space or portable structure used for the display of products or services. (SAF-AXM)

**Exhibit 3.14** illustrates an exhibit or exhibit booth on the floor of a trade show or exposition.

**3.3.80 Exhibitor.** An individual or entity engaged in the display of the products or services offered. (SAF-AXM)

**3.3.81\* Existing.** That which is already in existence on the date this edition of the *Code* goes into effect. (SAF-FUN)

**A.3.3.81 Existing.** See *Existing Building*, **A.3.3.36.5**.

**3.3.81.1 Approved Existing.** That which is already in existence on the date this edition of the *Code* goes into effect and is acceptable to the authority having jurisdiction. (SAF-FUN)

**3.3.82 Existing Building.** See **3.3.36.5**.

**Exhibit 3.14**

*An exhibit.*

**3.3.83\* Exit.** That portion of a means of egress that is separated from all other spaces of the building or structure by construction, location, or equipment as required to provide a protected way of travel to the exit discharge. (SAF-MEA)

**A.3.3.83 Exit.** Exits include exterior exit doors, exit passageways, horizontal exits, exit stairs, and exit ramps. In the case of a stairway, the exit includes the stair enclosure, the door to the stair enclosure, the stairs and landings inside the enclosure, the door from the stair enclosure to the outside or to the level of exit discharge, and any exit passageway and its associated doors, if such are provided, so as to discharge the stair directly to the outside. In the case of a door leading directly from the street floor to the street or open air, the exit comprises only the door. (See also **7.2.2.6.3.1** and **A.7.2.2.6.3.1**.)

Doors of small individual rooms, as in hotels, while constituting exit access from the room, are not referred to as exits, except where they lead directly to the outside of the building from the street floor.

The definition of the term *exit* was revised for the 2015 edition of the *Code* to add the word *location* so as to clarify that the

**Exhibit 3.15**

An enclosed stair that constitutes an exit.

requisite protected way of travel might be accomplished relative to where the exit is located. For example, a door opening to the outside from the main lobby of a building might be considered an exit, although the opening is not separated from other parts of the building. Exhibit 3.15 illustrates an enclosed exit stair that qualifies as being an exit because of its separation from the remainder of the building by fire-rated construction. See 7.1.3.2.

**3.3.83.1\* Horizontal Exit.** A way of passage from one building to an area of refuge in another building on approximately the same level, or a way of passage through or around a fire barrier to an area of refuge on approximately the same level in the same building that affords safety from fire and smoke originating from the area of incidence and areas communicating therewith. (SAF-MEA)

**A.3.3.83.1 Horizontal Exit.** Horizontal exits should not be confused with egress through doors in smoke barriers. Doors in smoke barriers are designed only for temporary protection against smoke, whereas horizontal exits provide protection against serious fire for a relatively long period of time in addition to providing immediate protection from smoke. (See 7.2.4.)

**3.3.84 Exit Access.** That portion of a means of egress that leads to an exit. (SAF-MEA)

**3.3.85 Exit Discharge.** That portion of a means of egress between the termination of an exit and a public way. (SAF-MEA)

**3.3.85.1\* Level of Exit Discharge.** The story that is either (1) the lowest story from which not less than 50 percent of the required number of exits and not less than 50 percent of the required egress capacity from such a story discharge directly outside at the finished ground level; or (2) where no story meets the conditions of item (1), the story that is provided with one or more exits that discharge directly to the outside to the finished ground level via the smallest elevation change. (SAF-MEA)

The definition of the term *level of exit discharge* is related to terminology used to describe building height and number of stories relative to grade plane, finished ground level (*Grade*), and level of exit discharge. See 3.3.126, *Grade Plane*, and 3.3.93, *Finished Ground Level (Grade)*. The term *level of exit discharge* is used in the commentary accompanying 4.6.3, which specifies how to determine stories in height.

The definition of *level of exit discharge* provides no allowance for having more than one level of exit discharge for a building. There is no primary or secondary level of exit discharge—only the level of exit discharge. The level designated as the level of exit discharge is used, for example, as the lowest floor for purposes of determining stories in height (see 4.6.3). Requirements related to minimum construction type are based on the number of stories in height used for a particular occupancy (see the 1.6 subsection of most of the occupancy chapters—for example, 12.1.6 for new assembly occupancies). The examples that follow demonstrate the application of the definition of the term *level of exit discharge* to a variety of building exit discharge arrangements.

#### Example 1

Exhibit 3.16 depicts a four-story building. The finished ground level varies little in elevation from building side to building side. The first story is the lowest story from which not less than 50 percent of the required number of means of egress and not less than 50 percent of the required egress capacity from that story discharge directly outside at the finished ground level. As such, it is designated as the level of exit discharge (LED).

#### Example 2

Exhibit 3.17 depicts a four-story building similar to that described in Example 1. The finished ground level varies in elevation from building side to building side. Both the first story and the second story are stories from which not less than 50 percent of the required number of means of egress and not less than 50 percent of the required egress capacity from that story discharge

Exhibit 3.16

Level of exit discharge at story with common finished ground level.

Exhibit 3.17

Level of exit discharge at lowest story.

directly outside at the finished ground level. The definition of *level of exit discharge* directs the *Code* user to designate the lowest such story (designated in Exhibit 3.17 as story 1) as the level of exit discharge (LED).

### Example 3

Exhibit 3.18 depicts a four-story building where the finished ground level varies significantly in elevation such that three of the floors have exits that discharge to the outside at or near finished ground level. Based on occupant load, each floor requires three means of egress that are supplied by three equally sized exit stairs and exit stair enclosure doors. Each of the exit stair enclosure doors from the three exit discharge floors provides less than 50 percent of the required number of means of egress discharging from that floor, so that the specification of item (1) of the definition of *level of exit discharge* in 3.3.85.1 is not met. Per item (2) of 3.3.85.1, the level of exit discharge is that exit discharge story with the smallest elevation change needed to reach the finished ground level. The floors designated in Exhibit 3.18 as 1 and

Exhibit 3.18

Level of exit discharge at exit story with least elevation difference from finished ground level.

3 require travel over stairs to reach the finished ground level. The floor designated as 2 discharges directly at finished ground level and is classified as the level of exit discharge (LED).

**A.3.3.85.1 Level of Exit Discharge.** Low occupancy, ancillary spaces with exit doors discharging directly to the outside, such as mechanical equipment rooms or storage areas, that are located on levels other than main occupiable floors should not be considered in the determination of level of exit discharge.

The text of A.3.3.85.1 advises that low occupancy spaces with exit doors discharging directly to the outside, such as mechanical equipment rooms that are located on levels other than main occupiable floors, should not be considered in the determination of level of exit discharge. Exhibit 3.19 depicts a building where the lowest floor (designated as -1) is occupied only for

Exhibit 3.19

Mechanical equipment floor disregarded in determination of level of exit discharge.

housing mechanical equipment and other building service equipment. It is the lowest story from which not less than 50 percent of the required number of means of egress and not less than 50 percent of the required egress capacity from that story discharge directly outside at the finished ground level and meets the definition of *level of exit discharge*. The annex text advises that the next to lowest floor (designated in [Exhibit 3.19](#) as 1) should be considered the level of exit discharge. The annex text was written in recognition of the fact that a floor level with few occupants and an exit door installed more for accommodating equipment moves than egress should not penalize the building operators in the application of provisions that rely on determination of level of exit discharge, as might be done when considering the number of stories in height for purposes of applying minimum construction requirements.

**3.3.86 Exposition.** An event in which the display of products or services is organized to bring together the provider and user of the products or services. (SAF-AXM)

**3.3.87 Exposition Facility.** See [3.3.90.1](#).

**3.3.88\* Exposure Fire.** A fire that starts at a location that is remote from the area being protected and grows to expose that which is being protected. (SAF-FUN)

**A.3.3.88 Exposure Fire.** An exposure fire usually refers to a fire that starts outside a building, such as a wildlands fire or vehicle fire, and that, consequently, exposes the building to a fire.

**3.3.89 Externally Illuminated.** See [3.3.146.1](#).

### 3.3.90 Facility.

**3.3.90.1 Exposition Facility.** A convention center, hotel, or other building at which exposition events are held. (SAF-AXM)

**3.3.90.2\* Limited Care Facility.** A building or portion of a building used on a 24-hour basis for the housing of four or more persons who are incapable of self-preservation because of age; physical limitations due to accident or illness; or limitations such as mental retardation/developmental disability, mental illness, or chemical dependency. (SAF-HEA)

**A.3.3.90.2 Limited Care Facility.** Limited care facilities and residential board and care occupancies both provide care to people with physical and mental limitations. However, the goals and programs of the two types of occupancies differ greatly. The requirements in this *Code* for limited care facilities are based on the assumption that these are medical facilities, that they provide medical care and treatment, and that the patients are not trained to respond to the fire alarm; that is, the patients do not participate in fire drills but, rather, await rescue. (See [Section 18.7](#).)

The requirements for residential board and care occupancies are based on the assumption that the residents are provided with personal care and activities that foster continued

independence, that the residents are encouraged and taught to overcome their limitations, and that most residents, including all residents in prompt and slow homes, are trained to respond to fire drills to the extent they are able. Residents are required to participate in fire drills. (See [Section 32.7](#).)

Persons with Alzheimer's and related illnesses might be located in a nursing home, limited care facility, or board and care facility. For such persons, it is the level of care provided, not the medical diagnosis, that matters for the purposes of determining whether the facility should meet the requirements for limited care. Where personal care is provided but medical or custodial care is not, the limited care definition does not typically apply. It is the intent of this definition that it not apply to persons not receiving medical or custodial care, provided they are able to assist in their own evacuation, regardless of their medical diagnosis.

**3.3.91 Festival Seating.** See [3.3.239.1](#).

### 3.3.92 Finish.

**3.3.92.1 Interior Ceiling Finish.** The interior finish of ceilings. (SAF-INT)

**3.3.92.2\* Interior Finish.** The exposed surfaces of walls, ceilings, and floors within buildings. (SAF-INT)

**A.3.3.92.2 Interior Finish.** Interior finish is not intended to apply to surfaces within spaces such as those that are concealed or inaccessible. Furnishings that, in some cases, might be secured in place for functional reasons should not be considered as interior finish.

**3.3.92.3\* Interior Floor Finish.** The interior finish of floors, ramps, stair treads and risers, and other walking surfaces. (SAF-INT)

**A.3.3.92.3 Interior Floor Finish.** Interior floor finish includes coverings applied over a normal finished floor or stair treads and risers.

**3.3.92.4 Interior Wall Finish.** The interior finish of columns, fixed or movable walls, and fixed or movable partitions. (SAF-INT)

[Exhibit 3.20](#) illustrates interior wall finish in the passenger concourse of an airport terminal building.

**3.3.93 Finished Ground Level (Grade).** The level of the finished ground (earth or other surface on ground). (See also [3.3.126, Grade Plane](#).) (SAF-FUN)

The definition of the term *finished ground level* is related to terminology used to describe building height and number of stories relative to grade plane and level of exit discharge. See [3.3.126, Grade Plane](#). See the commentary associated with [3.3.85.1, Level of Exit Discharge](#), where the term *finished ground level* is used in determining the level of exit discharge for a variety of exit discharge arrangements.

Exhibit 3.20

Interior wall finish.

**3.3.94 Fire Barrier.** See 3.3.31.1.

**3.3.95 Fire Barrier Wall.** See 3.3.288.1.

**3.3.96\* Fire Code.** The fire code enforced by the jurisdiction or agency enforcing this *Code* (SAF-FUN).

**A.3.3.96 Fire Code.** Where no fire code has been adopted, NFPA 1, *Fire Code*, should be used where the fire code is referenced in this *Code*.

The definition of the term *fire code* addresses a fire code in a generic sense in recognition of the fact that one common fire code is not used in all jurisdictions that use this *Code*. For examples of the use of the term *fire code* within the requirements of this *Code*, see 36.4.5.3(1) and 36.4.5.5(1).

**3.3.97 Fire Compartment.** See 3.3.48.1.

**3.3.98 Fire Door.** See 3.3.62.2.

**3.3.99 Fire Door Assembly.** See 3.3.23.1.1.

**3.3.100 Fire Exit Hardware.** See 3.3.135.1.

**3.3.101\* Fire Model.** A structured approach to predicting one or more effects of a fire. (SAF-FUN)

**A.3.3.101 Fire Model.** Due to the complex nature of the principles involved, models are often packaged as computer software. Any relevant input data, assumptions, and limitations needed to properly implement the model will be attached to the fire models.

**3.3.102 Fire Protection Rating.** See 3.3.223.1.

**3.3.103 Fire Resistance Rating.** See 3.3.223.2.

**3.3.104 Fire Safety Functions.** Building and fire control functions that are intended to increase the level of life safety for occupants or to control the spread of the harmful effects of fire. (SAF-BSF)

**3.3.105\* Fire Scenario.** A set of conditions that defines the development of fire, the spread of combustion products throughout a building or portion of a building, the reactions of people to fire, and the effects of combustion products. (SAF-FUN)

**A.3.3.105 Fire Scenario.** A fire scenario defines the conditions under which a proposed design is expected to meet the fire safety goals. Factors typically include fuel characteristics, ignition sources, ventilation, building characteristics, and occupant locations and characteristics. The term *fire scenario* includes more than the characteristics of the fire itself but excludes design specifications and any characteristics that do not vary from one fire to another; the latter are called assumptions. The term *fire scenario* is used here to mean only those specifications required to calculate the fire's development and effects, but, in other contexts, the term might be used to mean both the initial specifications and the subsequent development and effects (i.e., a complete description of fire from conditions prior to ignition to conditions following extinguishment).

**3.3.105.1 Design Fire Scenario.** A fire scenario selected for evaluation of a proposed design. (SAF-FUN)

**3.3.106 Fire Watch.** The assignment of a person or persons to an area for the express purpose of notifying the fire department, the building occupants, or both of an emergency; preventing a fire from occurring; extinguishing small fires; or protecting the public from fire or life safety dangers. [1, 2015] (SAF-BSF)

**3.3.107 Fire Window Assembly.** See 3.3.23.2.

**3.3.108 Fire-Rated Glazing.** Glazing with either a fire protection rating or a fire resistance rating. (SAF-FIR)

**3.3.109 Fire-Retardant-Treated Wood.** A wood product impregnated with chemical by a pressure process or other means during manufacture, treated to exhibit reduced surface-burning characteristics and resist propagation of fire. [703, 2015] (SAF-FIR)

**3.3.110 First Story Above Grade Plane.** See 3.3.126.1.

**3.3.111 Fixed Seating.** See 3.3.239.2.

**3.3.112\* Flame Spread.** The propagation of flame over a surface. (SAF-INT)

**A.3.3.112 Flame Spread.** See Section 10.2.

**3.3.113 Flame Spread Index.** See 3.3.149.1.

**3.3.114 Flashover.** A stage in the development of a contained fire in which all exposed surfaces reach ignition temperature more or less simultaneously and fire spreads rapidly throughout the space. (SAF-INT)

### 3.3.115 Flexible Plan and Open Plan Educational or Day-Care Building. See 3.3.36.6.

### 3.3.116 Floor Fire Door Assembly. See 3.3.23.1.1.1.

**3.3.117 Flow Time.** A component of total evacuation time that is the time during which there is crowd flow past a point in the means of egress system. (SAF-AXM)

**3.3.118 Fly Gallery.** A raised floor area above a stage from which the movement of scenery and operation of other stage effects are controlled. (SAF-AXM)

### 3.3.119 Foam Plastic Insulation. See 3.3.152.1.

### 3.3.120 Folding and Telescopic Seating. See 3.3.239.3.

### 3.3.121 Food Court. See 3.3.50.2.

### 3.3.122 Fuel Load. See 3.3.164.1.

### 3.3.123 General Industrial Occupancy. See 3.3.190.8.1.

**3.3.124 Goal.** A nonspecific overall outcome to be achieved that is measured on a qualitative basis. (SAF-FUN)

### 3.3.125 Grade. See 3.3.93, Finished Ground Level (Grade).

**3.3.126\* Grade Plane.** A reference plane upon which vertical measurements of a building are based representing the average of the finished ground level adjoining the building at all exterior walls. (SAF-FUN)

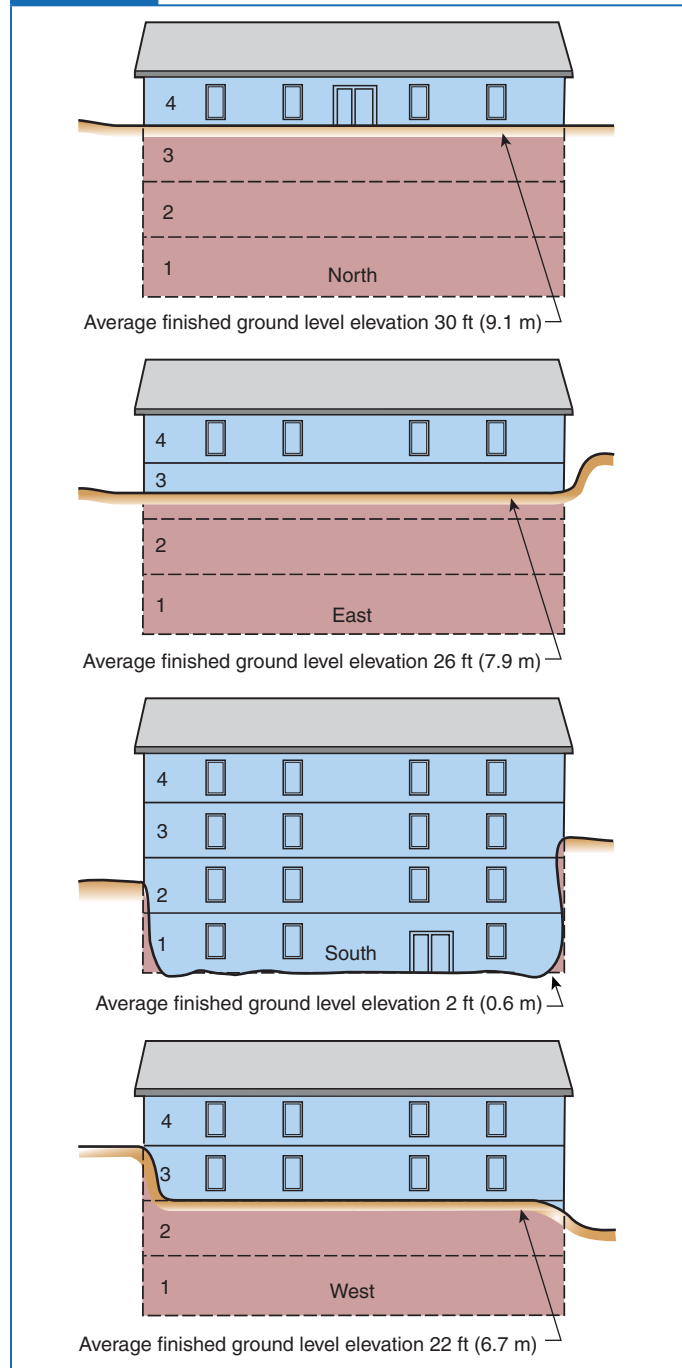

**A.3.3.126 Grade Plane.** See 4.6.15 for provisions for establishing the grade plane. Vertical measurements might be used in determining the number of stories or building height.

**3.3.126.1 First Story Above Grade Plane.** Any story having its finished floor surface entirely above grade plane, except that a basement is to be considered as a first story above grade plane where the finished surface of the floor above the basement is (1) more than 6 ft (1830 mm) above grade plane or (2) more than 12 ft (3660 mm) above the finished ground level at any point. (SAF-FUN)

The definition of the term *grade plane* was revised for the 2015 edition of the *Code* to remove requirements from the definition. The requirements were moved to 4.6.15. The definition of the terms *grade plane* and *first story above grade plane* are related to terminology used to describe building height and number of stories relative to grade plane, finished ground level, and level of exit discharge. See 3.3.93, *Finished Ground Level (Grade)*, and 3.3.85.1, *Level of Exit Discharge*.

Exhibit 3.21 demonstrates application of the definition of the term *grade plane*. The length and width of the building are each 200 ft (61 m). The finished ground level varies significantly in elevation from building side to building side. The average finished ground level elevation at each building side is as follows:

Exhibit 3.21

Grade plane determined in relation to finished ground level.

North side: 30 ft (9.1 m)

East side: 26 ft (7.9 m)

South side: 2 ft (0.6 m)

West side: 22 ft (6.7 m)

The average of the finished ground level elevation around the four sides of the building is the average of the four sides'

Exhibit 3.22

Grade plane and first story above grade plane.

average finished ground level, as the length and width are equal. If two sides of the building were twice as long as the other two sides, the two longer sides would have twice the effect in calculating the grade plane as the two shorter sides. In the example where all four sides are the same length, the average of the finished ground level is calculated as  $[30 \text{ ft} + 26 \text{ ft} + 2 \text{ ft} + 22 \text{ ft}]/4 = 20 \text{ ft}$  ( $[9.1 \text{ m} + 7.9 \text{ m} + 0.6 \text{ m} + 6.7 \text{ m}]/4 = 6.1 \text{ m}$ ). The grade plane is established as the elevation of 20 ft (6.1 m). The grade plane and the first story above grade plane (as defined in 3.3.124.1) are illustrated in Exhibit 3.22.

**3.3.127\* Grandstand.** A structure that provides tiered or stepped seating. (SAF-AXM)

**A.3.3.127 Grandstand.** Where the term *grandstand* is preceded by an adjective denoting a material, it means a grandstand the essential members of which, exclusive of seating, are of the material designated.

**3.3.128 Gridiron.** The structural framing over a stage supporting equipment for hanging or flying scenery and other stage effects. (SAF-AXM)

**3.3.129 Gross Floor Area.** See 3.3.21.2.1.

**3.3.130 Gross Leasable Area.** See 3.3.21.3.

**3.3.131 Guard.** A vertical protective barrier erected along exposed edges of stairways, balconies, and similar areas. (SAF-MEA)

Exhibit 3.23 illustrates guards at the open side of walking surfaces.

**3.3.132 Guest Room.** An accommodation combining living, sleeping, sanitary, and storage facilities within a compartment. (SAF-RES)

**3.3.133 Guest Suite.** See 3.3.273.1.

**3.3.134 Handrail.** A bar, pipe, or similar member designed to furnish persons with a handhold. (SAF-MEA)

Exhibit 3.23

Guards at the open side of walking surfaces.

### 3.3.135 Hardware.

**3.3.135.1 Fire Exit Hardware.** A type of panic hardware that additionally provides fire protection where used as part of a fire door assembly. (SAF-MEA)

The definition of the term *fire exit hardware* was revised for the 2015 edition of the Code. The definition of the term *panic hardware* (see 3.3.135.2) is adequate so as to permit the definition of fire exit hardware to build from it. Fire exit hardware is, in effect, panic hardware for use on a fire-rated door assembly. Exhibit 3.24 illustrates fire exit hardware on fire door assemblies that open into an expansive exit stair enclosure from the meeting room area of a hotel.

Exhibit 3.24

Fire exit hardware on fire door assemblies.

**3.3.135.2 Panic Hardware.** A door-latching assembly incorporating an actuating member or bar that releases the latch bolt upon the application of a force in the direction of egress travel. (SAF-MEA)

**Exhibit 3.25** illustrates panic hardware on the non-fire-rated main entrance doors of an elementary school.

**Exhibit 3.25**

*Panic hardware on main entrance doors that are not fire door assemblies.*

**3.3.136 Hazardous Area.** See 3.3.21.4.

**3.3.137 Health Care Occupancy.** See 3.3.190.7.

**3.3.138\* Heat Release Rate (HRR).** The rate at which heat energy is generated by burning. [921, 2014] (SAF-INT)

**A.3.3.138 Heat Release Rate (HRR).** The heat release rate of a fuel is related to its chemistry, physical form, and availability of oxidant and is ordinarily expressed as British thermal units per second (Btu/s) or kilowatts (kW).

Chapters 40 and 42 include detailed provisions on high hazard industrial and storage occupancies.

**3.3.139 High Hazard Industrial Occupancy.** See 3.3.190.8.2.

**3.3.140 High-Rise Building.** See 3.3.36.7.

**3.3.141 Historic Building.** See 3.3.36.8.

**3.3.142 Home.**

**3.3.142.1\* Day-Care Home.** A building or portion of a building in which more than 3 but not more than 12 clients receive care, maintenance, and supervision, by other than their relative(s) or legal guardians(s), for less than 24 hours per day. (SAF-END)

**A.3.3.142.1 Day-Care Home.** A day-care home is generally located within a dwelling unit.

**3.3.142.2 Nursing Home.** A building or portion of a building used on a 24-hour basis for the housing and nursing care of four or more persons who, because of mental or physical incapacity, might be unable to provide for their own needs and safety without the assistance of another person. (SAF-HEA)

**3.3.143 Horizontal Exit.** See 3.3.83.1.

**3.3.144 Hospital.** A building or portion thereof used on a 24-hour basis for the medical, psychiatric, obstetrical, or surgical care of four or more inpatients. (SAF-HEA)

**3.3.145\* Hotel.** A building or groups of buildings under the same management in which there are sleeping accommodations for more than 16 persons and primarily used by transients for lodging with or without meals. (SAF-RES)

**A.3.3.145 Hotel.** So-called apartment hotels should be classified as hotels, because they are potentially subject to the same transient occupancy as hotels. Transients are those who occupy accommodations for less than 30 days.

**3.3.146 Illuminated.**

**3.3.146.1\* Externally Illuminated.** Refers to an illumination source that is contained outside of the device or sign legend area that is to be illuminated. (SAF-MEA)

**A.3.3.146.1 Externally Illuminated.** The light source is typically a dedicated incandescent or fluorescent source.

**Exhibit 3.26** illustrates a required sign (see 7.10.8.3.1) that is externally illuminated by luminaires in the vicinity of the door opening.

**3.3.146.2\* Internally Illuminated.** Refers to an illumination source that is contained inside the device or legend that is illuminated. (SAF-MEA)

**Exhibit 3.26**

*Required sign that is externally illuminated.*

Exhibit 3.27

Two directional exit signs that are internally illuminated.

**A.3.3.146.2 Internally Illuminated.** The light source is typically incandescent, fluorescent, electroluminescent, photo-luminescent, or self-luminous or is a light-emitting diode(s).

Exhibit 3.27 illustrates two directional exit signs that are internally illuminated. The sign that is mounted from the ceiling receives its illumination from a source positioned above the EXIT legend. The floor proximity sign (see 7.10.1.6) receives its illumination from a source positioned behind the EXIT legend.

**3.3.147 Impractical Evacuation Capability.** See 3.3.78.1.

**3.3.148 Incapacitation.** A condition under which humans do not function adequately and become unable to escape untenable conditions. (SAF-FUN)

**3.3.149 Index.**

**3.3.149.1 Flame Spread Index.** A comparative measure, expressed as a dimensionless number, derived from visual measurements of the spread of flame versus time for a material tested in accordance with ASTM E 84, *Standard Test Method for Surface Burning Characteristics of Building Materials*,

or ANSI/UL 723, *Standard for Test for Surface Burning Characteristics of Burning Materials*. (SAF-INT)

**3.3.149.2 Smoke Developed Index.** A comparative measure, expressed as a dimensionless number, derived from measurements of smoke obscuration versus time for a material tested in accordance with ASTM E 84, *Standard Test Method for Surface Burning Characteristics of Building Materials*, or ANSI/UL 723, *Standard for Test for Surface Burning Characteristics of Burning Materials*. (SAF-INT)

**3.3.150 Industrial Occupancy.** See 3.3.190.8.

**3.3.151 Input Data Specification.** See 3.3.262.2.

**3.3.152 Insulation.**

**3.3.152.1 Foam Plastic Insulation.** A cellular plastic, used for thermal insulating or acoustical applications, having a density of 20 lb/ft<sup>3</sup> (320 kg/m<sup>3</sup>) or less, containing open or closed cells, and formed by a foaming agent. (SAF-INT)

**3.3.152.2 Reflective Insulation.** Thermal insulation consisting of one or more low-emittance surfaces bounding one or more enclosed air spaces. (SAF-INT)

**3.3.153 Interior Ceiling Finish.** See 3.3.92.1.

**3.3.154 Interior Finish.** See 3.3.92.2.

**3.3.155 Interior Floor Finish.** See 3.3.92.3.

**3.3.156 Interior Wall Finish.** See 3.3.92.4.

**3.3.157 Internally Illuminated.** See 3.3.146.2.

**3.3.158 Joint.** A linear opening in or between adjacent assemblies that is designed to allow independent movement of the building. (SAF-FIR)

**3.3.159 Level of Exit Discharge.** See 3.3.85.1.

**3.3.160 Life Safety Evaluation.** A written review dealing with the adequacy of life safety features relative to fire, storm, collapse, crowd behavior, and other related safety considerations. (SAF-AXM)

**3.3.161 Limited Access Structure.** See 3.3.272.3.

**3.3.162 Limited Care Facility.** See 3.3.90.2.

**3.3.163 Living Area.** See 3.3.21.5.

**3.3.164 Load.**

**3.3.164.1\* Fuel Load.** The total quantity of combustible contents of a building, space, or fire area. (SAF-FUN)

**A.3.3.164.1 Fuel Load.** Fuel load includes interior finish and trim.

**3.3.164.2 Occupant Load.** The total number of persons that might occupy a building or portion thereof at any one time. (SAF-MEA)

**3.3.165 Load-Bearing Element.** Any column, girder, beam, joist, truss, rafter, wall, floor, or roof sheathing that supports any vertical load in addition to its own weight, or any lateral load. (SAF-FIR)

**3.3.166 Lock-Up.** An incidental use area in other than a detention and correctional occupancy where occupants are restrained and such occupants are mostly incapable of self-preservation because of security measures not under the occupants' control. (SAF-DET)

The definition of the term *lock-up* includes the words "an incidental use area" to prevent *Code* users from incorrectly using the term *lock-up* for a building predominantly used for the detention of persons but for which the provisions of 22.4.5.1.1 or 23.4.5.1.1 would not impose a classification of detention and correctional occupancy because the number of detainees does not exceed 49. Where the predominant use of the building is the detention of persons, the occupancy should be classified as detention and correctional and subject to the full provisions of Chapter 22 or Chapter 23, not to the lock-up provisions of 22.4.5 or 23.4.5. The lock-up provisions of 22.4.5 and 23.4.5 are meant to be applied to detention areas where the predominant use is something other than detention — as might occur, for example, at immigration control at an international airport or the security office at a sports stadium or mercantile mall building.

**3.3.167 Lodging or Rooming House.** A building or portion thereof that does not qualify as a one- or two-family dwelling, that provides sleeping accommodations for a total of 16 or fewer people on a transient or permanent basis, without personal care services, with or without meals, but without separate cooking facilities for individual occupants. (SAF-RES)

**3.3.168 Major Tenant.** A tenant space, in a mall building, with one or more main entrances from the exterior that also serve as exits and are independent of the mall. (SAF-MER)

The definition of the term *major tenant* helps to support the criteria of 36.4.4.6.6 and 37.4.4.6.6, which require each major tenant of a mercantile mall to provide a minimum of one-half of its means of egress independent of the mall, thus reducing the overall occupant load for which the mall's egress system must be sized.

**3.3.169 Mall.** A roofed or covered common pedestrian area within a mall building that serves as access for two or more tenants and does not exceed three levels that are open to each other. (SAF-MER)

Exhibit 3.28 illustrates the mall or covered pedestrian area in a mall building.

**3.3.170 Mall Building.** See 3.3.36.9.

**3.3.171 Material.**

Exhibit 3.28

Mall or covered pedestrian area.

**3.3.171.1 Combustible (Material).** A material that, in the form in which it is used and under the conditions anticipated, will ignite and burn; a material that does not meet the definition of noncombustible or limited-combustible. (SAF-FUN)

**3.3.171.2 Limited-Combustible (Material).** See 4.6.14.

**3.3.171.3 Metal Composite Material (MCM).** A factory-manufactured panel consisting of metal skins bonded to both faces of a core made of any plastic other than foamed plastic insulation as defined in 3.3.152.1. (SAF-MER)

**3.3.171.4 Noncombustible (Material).** See 4.6.13.

**3.3.171.5 Weathered-Membrane Material.** Membrane material that has been subjected to a minimum of 3000 hours in a weatherometer in accordance with ASTM G 155, *Standard Practice for Operating Xenon Arc Light Apparatus for Exposure of Non-Metallic Materials*, or approved equivalent. (SAF-IND)

**3.3.172\* Means of Egress.** A continuous and unobstructed way of travel from any point in a building or structure to a public way consisting of three separate and distinct parts: (1) the exit access, (2) the exit, and (3) the exit discharge. (SAF-MEA)

**A.3.3.172 Means of Egress.** A means of egress comprises the vertical and horizontal travel and includes intervening room spaces, doorways, hallways, corridors, passageways, balconies, ramps, stairs, elevators, enclosures, lobbies, escalators, horizontal exits, courts, and yards.

**3.3.172.1 Accessible Means of Egress.** A means of egress that provides an accessible route to an area of refuge, a horizontal exit, or a public way. (SAF-MEA)

**3.3.173 Means of Escape.** A way out of a building or structure that does not conform to the strict definition of means of egress but does provide an alternate way out. (SAF-MEA)

**3.3.174\* Membrane.** A thin layer of construction material. (SAF-FIR)

**A.3.3.174 Membrane.** For the purpose of fire protection features, a membrane can consist of materials such as gypsum board, plywood, glass, or fabric. For the purpose of membrane structures, a membrane consists of thin, flexible, water-impervious material capable of being supported by an air pressure of 1½ in. (38 mm) water column.

**3.3.175 Membrane Structure.** See 3.3.272.4.

**3.3.176 Mercantile Occupancy.** See 3.3.190.9.

**3.3.177 Metal Composite Material (MCM).** See 3.3.171.3.

**3.3.178 Mezzanine.** An intermediate level between the floor and the ceiling of any room or space. (SAF-FIR)

**3.3.179 Mixed Occupancy.** See 3.3.190.10.

**3.3.180\* Modification.** The reconfiguration of any space; the addition or elimination of any door or window; the addition or elimination of load-bearing elements; the reconfiguration or extension of any system; or the installation of any additional equipment. (SAF-FUN)

**A.3.3.180 Modification.** Modification does not include repair or replacement of interior finishes.

**Exhibit 3.29** illustrates a rehabilitation project that might be classified as modification due to the reconfiguration of the space.

**Exhibit 3.29**

*Rehabilitation project classified as modification.*

**3.3.181 Multilevel Play Structure.** See 3.3.272.5.

**3.3.182 Multiple Occupancy.** See 3.3.190.11.

**3.3.183 Multiple Station Alarm Device.** See 3.3.61.2.

**3.3.184 Multipurpose Assembly Occupancy.** See 3.3.190.2.1.

**3.3.185 Net Floor Area.** See 3.3.21.2.2.

**3.3.186 Non-Patient-Care Suite (Health Care Occupancies).** See 3.3.273.2.

**3.3.187 Normally Unoccupied Building Service Equipment Support Area.** See 3.3.21.6.

**3.3.188 Nursing Home.** See 3.3.142.2.

**3.3.189\* Objective.** A requirement that needs to be met to achieve a goal. (SAF-FUN)

**A.3.3.189 Objective.** Objectives define a series of actions necessary to make the achievement of a goal more likely. Objectives are stated in more specific terms than goals and are measured on a more quantitative, rather than qualitative, basis.

**3.3.190 Occupancy.** The purpose for which a building or other structure, or part thereof, is used or intended to be used. [ASCE/SEI 7:1.2] (SAF-FUN)

**3.3.190.1\* Ambulatory Health Care Occupancy.** An occupancy used to provide services or treatment simultaneously to four or more patients that provides, on an outpatient basis, one or more of the following: (1) treatment for patients that renders the patients incapable of taking action for self-preservation under emergency conditions without the assistance of others; (2) anesthesia that renders the patients incapable of taking action for self-preservation under emergency conditions without the assistance of others; (3) emergency or urgent care for patients who, due to the nature of their injury or illness, are incapable of taking action for self-preservation under emergency conditions without the assistance of others. (SAF-HEA)

**A.3.3.190.1 Ambulatory Health Care Occupancy.** It is not the intent that occupants be considered to be incapable of self-preservation just because they are in a wheelchair or use assistive walking devices, such as a cane, a walker, or crutches. Rather, it is the intent to address emergency care centers that receive patients who have been rendered incapable of self-preservation due to the emergency, such as being rendered unconscious as a result of an accident or being unable to move due to sudden illness.

It is not the intent that the term *anesthesia* be limited to general anesthesia.

**3.3.190.2\* Assembly Occupancy.** An occupancy (1) used for a gathering of 50 or more persons for deliberation, worship, entertainment, eating, drinking, amusement, awaiting transportation, or similar uses; or (2) used as a special amusement building, regardless of occupant load. (SAF-AXM)

**A.3.3.190.2 Assembly Occupancy.** Assembly occupancies might include the following:

- (1) Armories
- (2) Assembly halls
- (3) Auditoriums
- (4) Bowling lanes
- (5) Club rooms
- (6) College and university classrooms, 50 persons and over
- (7) Conference rooms
- (8) Courtrooms
- (9) Dance halls
- (10) Drinking establishments
- (11) Exhibition halls
- (12) Gymnasiums
- (13) Libraries
- (14) Mortuary chapels
- (15) Motion picture theaters
- (16) Museums
- (17) Passenger stations and terminals of air, surface, underground, and marine public transportation facilities
- (18) Places of religious worship
- (19) Pool rooms
- (20) Recreation piers
- (21) Restaurants
- (22) Skating rinks
- (23) Special amusement buildings, regardless of occupant load
- (24) Theaters

Assembly occupancies are characterized by the presence or potential presence of crowds with attendant panic hazard in case of fire or other emergency. They are generally open or occasionally open to the public, and the occupants, who are present voluntarily, are not ordinarily subject to discipline or control. Such buildings are ordinarily occupied by able-bodied persons and are not used for sleeping purposes. Special conference rooms, snack areas, and other areas incidental to, and under the control of, the management of other occupancies, such as offices, fall under the 50-person limitation.

Restaurants and drinking establishments with an occupant load of fewer than 50 persons should be classified as mercantile occupancies.

For special amusement buildings, see [12.4.8](#) and [13.4.8](#).

**3.3.190.2.1 Multipurpose Assembly Occupancy.** An assembly room designed to accommodate temporarily any of several possible assembly uses. (SAF-AXM)

**3.3.190.3\* Business Occupancy.** An occupancy used for the transaction of business other than mercantile. (SAF-MER)

**A.3.3.190.3 Business Occupancy.** Business occupancies include the following:

- (1) Air traffic control towers (ATCTs)
- (2) City halls
- (3) College and university instructional buildings, classrooms under 50 persons, and instructional laboratories
- (4) Courthouses
- (5) Dentists' offices
- (6) Doctors' offices
- (7) General offices
- (8) Outpatient clinics (ambulatory)
- (9) Town halls

Doctors' and dentists' offices are included, unless of such character as to be classified as ambulatory health care occupancies. (See [3.3.190.1](#).)

Birth centers should be classified as business occupancies if they are occupied by fewer than four patients, not including infants, at any one time; do not provide sleeping facilities for four or more occupants; and do not provide treatment procedures that render four or more patients, not including infants, incapable of self-preservation at any one time. For birth centers occupied by patients not meeting these parameters, see [Chapter 18](#) or [Chapter 19](#), as appropriate.

Service facilities common to city office buildings, such as newsstands, lunch counters serving fewer than 50 persons, barber shops, and beauty parlors are included in the business occupancy group.

City halls, town halls, and courthouses are included in this occupancy group, insofar as their principal function is the transaction of public business and the keeping of books and records. Insofar as they are used for assembly purposes, they are classified as assembly occupancies.

**3.3.190.4\* Day-Care Occupancy.** An occupancy in which four or more clients receive care, maintenance, and supervision, by other than their relatives or legal guardians, for less than 24 hours per day. (SAF-END)

**A.3.3.190.4 Day-Care Occupancy.** Day-care occupancies include the following:

- (1) Adult day-care occupancies, except where part of a health care occupancy
- (2) Child day-care occupancies
- (3) Day-care homes
- (4) Kindergarten classes that are incidental to a child day-care occupancy
- (5) Nursery schools

In areas where public schools offer only half-day kindergarten programs, many child day-care occupancies offer state-approved kindergarten classes for children who need full-day care. Because these classes are normally incidental to the day-care occupancy, the requirements of the day-care occupancy should be followed.

**3.3.190.5\* Detention and Correctional Occupancy.** An occupancy used to house one or more persons under varied degrees of restraint or security where such occupants are mostly incapable of self-preservation because of security measures not under the occupants' control. (SAF-DET)

**A.3.3.190.5 Detention and Correctional Occupancy.** Detention and correctional occupancies include the following:

- (1) Adult and juvenile substance abuse centers
- (2) Adult and juvenile work camps
- (3) Adult community residential centers
- (4) Adult correctional institutions
- (5) Adult local detention facilities
- (6) Juvenile community residential centers
- (7) Juvenile detention facilities
- (8) Juvenile training schools

See [A.22.1.1.1.6](#) and [A.23.1.1.1.6](#).

**3.3.190.6\* Educational Occupancy.** An occupancy used for educational purposes through the twelfth grade by six or more persons for 4 or more hours per day or more than 12 hours per week. (SAF-END)

**A.3.3.190.6 Educational Occupancy.** Educational occupancies include the following:

- (1) Academies
- (2) Kindergartens
- (3) Schools

An educational occupancy is distinguished from an assembly occupancy in that the same occupants are regularly present.

**3.3.190.7\* Health Care Occupancy.** An occupancy used to provide medical or other treatment or care simultaneously to four or more patients on an inpatient basis, where such patients are mostly incapable of self-preservation due to age, physical or mental disability, or because of security measures not under the occupants' control. (SAF-HEA)

**A.3.3.190.7 Health Care Occupancy.** Health care occupancies include the following:

- (1) Hospitals
- (2) Limited care facilities
- (3) Nursing homes

Occupants of health care occupancies typically have physical or mental illness, disease, or infirmity. They also include infants, convalescents, or infirm aged persons. It is not the intent to consider occupants incapable of self-preservation because they are in a wheelchair or use assistive walking devices, such as a cane, a walker, or crutches.

**3.3.190.8\* Industrial Occupancy.** An occupancy in which products are manufactured or in which processing, assembling, mixing, packaging, finishing, decorating, or repair operations are conducted. (SAF-IND)

**A.3.3.190.8 Industrial Occupancy.** Industrial occupancies include the following:

- (1) Drycleaning plants
- (2) Factories of all kinds
- (3) Food processing plants
- (4) Gas plants
- (5) Hangars (for servicing/maintenance)
- (6) Laundries
- (7) Power plants
- (8) Pumping stations
- (9) Refineries
- (10) Sawmills
- (11) Telephone exchanges

In evaluating the appropriate classification of laboratories, the authority having jurisdiction should treat each case individually, based on the extent and nature of the associated hazards. Some laboratories are classified as occupancies other than industrial; for example, a physical therapy laboratory or a computer laboratory.

**3.3.190.8.1\* General Industrial Occupancy.** An industrial occupancy in which ordinary and low hazard industrial operations are conducted in buildings of conventional design suitable for various types of industrial processes. (SAF-IND)

**A.3.3.190.8.1 General Industrial Occupancy.** General industrial occupancies include multistory buildings where floors are occupied by different tenants or buildings suitable for such occupancy and, therefore, are subject to possible use for types of industrial processes with a high density of employee population.

**3.3.190.8.2\* High Hazard Industrial Occupancy.** An industrial occupancy in which industrial operations that include high hazard materials, processes, or contents are conducted. (SAF-IND)

**A.3.3.190.8.2 High Hazard Industrial Occupancy.** A high hazard industrial occupancy includes occupancies where gasoline and other flammable liquids are handled, used, or stored under such conditions that involve possible release of flammable vapors; where grain dust, wood flour or plastic dust, aluminum or magnesium dust, or other explosive dusts are produced; where hazardous chemicals or explosives are manufactured, stored, or handled; where materials are processed or handled under conditions that might produce flammable flyings; and where other situations of similar hazard exist. [Chapters 40](#) and [42](#) include detailed provisions on high hazard industrial and storage occupancies.

**3.3.190.8.3 Special-Purpose Industrial Occupancy.** An industrial occupancy in which ordinary and low hazard industrial operations are conducted in buildings designed for, and suitable only for, particular types of operations, characterized by a relatively low density of employee population, with much of the area occupied by machinery or equipment. (SAF-IND)

**3.3.190.9\* Mercantile Occupancy.** An occupancy used for the display and sale of merchandise. (SAF-MER)

**A.3.3.190.9 Mercantile Occupancy.** Mercantile occupancies include the following:

- (1) Auction rooms
- (2) Department stores
- (3) Drugstores
- (4) Restaurants with fewer than 50 persons
- (5) Shopping centers
- (6) Supermarkets

Office, storage, and service facilities incidental to the sale of merchandise and located in the same building should be considered part of the mercantile occupancy classification.

**3.3.190.10 Mixed Occupancy.** A multiple occupancy where the occupancies are intermingled. (SAF-FUN)

**3.3.190.11 Multiple Occupancy.** A building or structure in which two or more classes of occupancy exist. (SAF-FUN)

**3.3.190.12\* Residential Board and Care Occupancy.** An occupancy used for lodging and boarding of four or more residents, not related by blood or marriage to the owners or operators, for the purpose of providing personal care services. (SAF-BCF)

**A.3.3.190.12 Residential Board and Care Occupancy.** The following are examples of facilities that are classified as residential board and care occupancies:

- (1) Group housing arrangement for physically or mentally handicapped persons who normally attend school in the community, attend worship in the community, or otherwise use community facilities
- (2) Group housing arrangement for physically or mentally handicapped persons who are undergoing training in preparation for independent living, for paid employment, or for other normal community activities
- (3) Group housing arrangement for the elderly that provides personal care services but that does not provide nursing care
- (4) Facilities for social rehabilitation, alcoholism, drug abuse, or mental health problems that contain a group housing arrangement and that provide personal care services but do not provide acute care
- (5) Assisted living facilities
- (6) Other group housing arrangements that provide personal care services but not nursing care

**3.3.190.13\* Residential Occupancy.** An occupancy that provides sleeping accommodations for purposes other than health care or detention and correctional. (SAF-RES)

**A.3.3.190.13 Residential Occupancy.** Residential occupancies are treated as separate occupancies in this *Code* as follows:

- (1) One- and two-family dwellings (Chapter 24)
- (2) Lodging or rooming houses (Chapter 26)

- (3) Hotels, motels, and dormitories (Chapters 28 and 29)
- (4) Apartment buildings (Chapters 30 and 31)

**3.3.190.14 Separated Occupancy.** A multiple occupancy where the occupancies are separated by fire resistance-rated assemblies. (SAF-FUN)

**3.3.190.15\* Storage Occupancy.** An occupancy used primarily for the storage or sheltering of goods, merchandise, products, or vehicles. (SAF-IND)

**A.3.3.190.15 Storage Occupancy.** Storage occupancies include the following:

- (1) Barns
- (2) Bulk oil storage
- (3) Cold storage
- (4) Freight terminals
- (5) Grain elevators
- (6) Hangars (for storage only)
- (7) Parking structures
- (8) Truck and marine terminals
- (9) Warehouses

Storage occupancies are characterized by the presence of relatively small numbers of persons in proportion to the area.

**3.3.191 Occupant Characteristics.** The abilities or behaviors of people before and during a fire. (SAF-FUN)

**3.3.192 Occupant Load.** See 3.3.164.2.

**3.3.193 Occupiable Area.** See 3.3.21.7.

**3.3.194 Occupiable Story.** See 3.3.269.1.

**3.3.195 One- and Two-Family Dwelling Unit.** See 3.3.66.1.

**3.3.196 One-Family Dwelling Unit.** See 3.3.66.2.

**3.3.197 Open Parking Structure.** See 3.3.272.7.4.

**3.3.198 Open Structure.** See 3.3.272.6.

**3.3.199 Open-Air Mercantile Operation.** An operation conducted outside of all structures, with the operations area devoid of all walls and roofs except for small, individual, weather canopies. (SAF-MER)

**3.3.200 Outside Stair.** See 3.3.265.2.

**3.3.201 Panic Hardware.** See 3.3.135.2.

**3.3.202 Parking Structure.** See 3.3.272.7.

**3.3.203 Patient Care Non-Sleeping Suite (Health Care Occupancies).** See 3.3.273.3.

**3.3.204 Patient Care Sleeping Suite (Health Care Occupancies).** See 3.3.273.4.

**3.3.205 Patient Care Suite (Health Care Occupancies).** See [3.3.273.5](#).

**3.3.206\* Performance Criteria.** Threshold values on measurement scales that are based on quantified performance objectives. (SAF-FUN)

**A.3.3.206 Performance Criteria.** Performance criteria are stated in engineering terms. Engineering terms include temperatures, radiant heat flux, and levels of exposure to fire products. Performance criteria provide threshold values used to evaluate a proposed design.

**3.3.207 Permanent Structure.** See [3.3.272.8](#).

**3.3.208\* Personal Care.** The care of residents who do not require chronic or convalescent medical or nursing care. (SAF-BCF)

**A.3.3.208 Personal Care.** Personal care involves responsibility for the safety of the resident while inside the building. Personal care might include daily awareness by management of the resident's functioning and whereabouts, making and reminding a resident of appointments, the ability and readiness for intervention in the event of a resident experiencing a crisis, supervision in the areas of nutrition and medication, and actual provision of transient medical care.

**3.3.209\* Photoluminescent.** Having the ability to store incident electromagnetic radiation typically from ambient light sources, and release it in the form of visible light. [301, 2013] (SAF-MEA)

**A.3.3.209 Photoluminescent.** The released light is normally visible for a limited time if the ambient light sources are removed or partially obscured.

**Exhibit 3.30** illustrates photoluminescent material applied, in the form of the running man exit symbol and associated chevron-shaped directional indicator, to a wall panel of an exhibit at a trade show. The same material is used for exit signs and egress path marking. See [7.10.7.2](#) and [7.2.2.5.5.10](#).

**3.3.210 Pinrail.** A rail on or above a stage through which belaying pins are inserted and to which lines are fastened. (SAF-AXM)

**3.3.211\* Platform.** The raised area within a building used for the presentation of music, plays, or other entertainment. (SAF-AXM)

**A.3.3.211 Platform.** Platforms also include the head tables for special guests; the raised area for lecturers and speakers; boxing and wrestling rings; theater-in-the-round; and for similar purposes wherein there are no overhead drops, pieces of scenery, or stage effects other than lighting and a screening valance.

**Exhibit 3.30**

*Photoluminescent material applied to an exhibit wall.*

A platform is not intended to be prohibited from using a curtain as a valance to screen or hide the electric conduit, lighting track, or similar fixtures, nor is a platform prohibited from using curtains that are used to obscure the back wall of the stage; from using a curtain between the auditorium and the stage (grand or house curtain); from using a maximum of four leg drops; or from using a valance to screen light panels, plumbing, and similar equipment from view.

The raised area at the back of the photo in [Exhibit 3.31](#) illustrates a platform. The platform is part of a multipurpose room in an elementary school. See also the definition of *stage* and its sub-definitions in [3.3.264](#).

**3.3.211.1 Temporary Platform.** A platform erected within an area for not more than 30 days. (SAF-AXM)

**3.3.212 Plenum.** A compartment or chamber to which one or more air ducts are connected and that forms part of the air-distribution system. (SAF-FIR)

**3.3.213 Point of Safety.** A location that (a) is exterior to and away from a building; or (b) is within a building of any construction type protected throughout by an approved automatic sprinkler system and that is either (1) within an exit enclosure meeting the requirements of this *Code*, or (2) within another portion of the building that is separated by smoke barriers in accordance

Exhibit 3.31

Platform in a multipurpose room of an elementary school.

with [Section 8.5](#) having a minimum ½-hour fire resistance rating, and that portion of the building has access to a means of escape or exit that conforms to the requirements of this *Code* and does not necessitate return to the area of fire involvement; or (c) is within a building of Type I, Type II(222), Type II(111), Type III(211), Type IV, or Type V(111) construction (*see* [8.2.1.2](#)) and is either (1) within an exit enclosure meeting the requirements of this *Code*, or (2) within another portion of the building that is separated by smoke barriers in accordance with [Section 8.5](#) having a minimum ½-hour fire resistance rating, and that portion of the building has access to a means of escape or exit that conforms to the requirements of this *Code* and does not necessitate return to the area of fire involvement. (SAF-BCF)

**3.3.214 Previously Approved.** That which was acceptable to the authority having jurisdiction prior to the date this edition of the *Code* went into effect. (SAF-FUN)

**3.3.215 Private Party Tent.** *See* [3.3.279.1](#). (SAF-AXM)

**3.3.216 Professional Engineer.** A person registered or licensed to practice engineering in a jurisdiction, subject to all laws and limitations imposed by the jurisdiction. (SAF-FUN)

**3.3.217 Prompt Evacuation Capability.** *See* [3.3.78.2](#). (SAF-BCF)

**3.3.218\* Proposed Design.** A design developed by a design team and submitted to the authority having jurisdiction for approval. (SAF-FUN)

**A.3.3.218 Proposed Design.** The design team might develop a number of trial designs that will be evaluated to determine whether they meet the performance criteria. One of the trial designs will be selected from those that meet the performance criteria for submission to the authority having jurisdiction as the proposed design.

The proposed design is not necessarily limited to fire protection systems and building features. It also includes any component of the proposed design that is installed, established, or maintained for the purpose of life safety, without which the proposed design could fail to achieve specified performance criteria. Therefore, the proposed design often includes emergency procedures and organizational structures that are needed to meet the performance criteria specified for the proposed design.

**3.3.219 Proscenium Wall.** *See* [3.3.288.2](#).

**3.3.220 Public Way.** A street, alley, or other similar parcel of land essentially open to the outside air deeded, dedicated, or otherwise permanently appropriated to the public for public use and having a clear width and height of not less than 10 ft (3050 mm). (SAF-MEA)

**3.3.221\* Ramp.** A walking surface that has a slope steeper than 1 in 20. (SAF-MEA)

**A.3.3.221 Ramp.** *See* [7.2.5](#).

**3.3.221.1 Aisle Ramp.** A ramp within a seating area of an assembly occupancy that directly serves rows of seating to the side of the ramp. (SAF-AXM)

**3.3.222 Ramp Type Parking Structure.** *See* [3.3.272.7.5](#).

**3.3.223 Rating.**

**3.3.223.1\* Fire Protection Rating.** The designation indicating the duration of the fire test exposure to which an opening protective assembly was exposed. [221, 2015] (SAF-FIR)

**A.3.3.223.1 Fire Protection Rating.** The acceptance criteria for determining fire protection ratings for fire door assemblies are described in NFPA 252, *Standard Methods of Fire Tests of Door Assemblies*, and those for fire window assemblies are described in NFPA 257, *Standard on Fire Test for Window and Glass Block Assemblies*.

**3.3.223.2 Fire Resistance Rating.** The time, in minutes or hours, that materials or assemblies have withstood a fire exposure as determined by the tests, or methods based on tests, prescribed by this *Code*. (SAF-FIR)

**3.3.224\* Reconstruction.** The reconfiguration of a space that affects an exit or a corridor shared by more than one occupant space; or the reconfiguration of a space such that the rehabilitation work area is not permitted to be occupied because existing means of egress and fire protection systems, or their equivalent, are not in place or continuously maintained. (SAF-FUN)

**A.3.3.224 Reconstruction.** It is not the intent that a corridor, an aisle, or a circulation space within a suite be considered as a corridor that is shared by more than one occupant space. The suite should be considered as only one occupant space. The

following situations should be considered to involve more than one occupant space:

- (1) Work affecting a corridor that is common to multiple guest rooms on a floor of a hotel occupancy
- (2) Work affecting a corridor that is common to multiple living units on a floor of an apartment building occupancy
- (3) Work affecting a corridor that is common to multiple tenants on a floor of a business occupancy

**3.3.225 Reflective Insulation.** See 3.3.152.2.

**3.3.226 Registered Architect.** A person licensed to practice architecture in a jurisdiction, subject to all laws and limitations imposed by the jurisdiction. (SAF-FUN)

**3.3.227 Registered Design Professional (RDP).** An individual who is registered or licensed to practice his/her respective design profession as defined by the statutory requirements of the professional registration laws of the state or jurisdiction in which the project is to be constructed. (SAF-FUN)

**3.3.228 Regular Stage.** See 3.3.264.2.

**3.3.229 Rehabilitation Work Area.** See 3.3.21.8.

**3.3.230 Relocation.** The movement of occupants to a safer area within the same building. (SAF-FUN)

The definition of the term *relocation* is new for the 2015 edition of the *Code*. It is common to relocate into a safe area of the building as an evacuation strategy under certain emergency conditions. See 4.8.2.1(3) and the extensive annex text of A.4.8.2.1(3).

**3.3.231 Repair.** The patching, restoration, or painting of materials, elements, equipment, or fixtures for the purpose of maintaining such materials, elements, equipment, or fixtures in good or sound condition. (SAF-FUN)

**3.3.232 Residential Board and Care Occupancy.** See 3.3.190.12.

**3.3.233 Residential Board and Care Resident.** A person who receives personal care and resides in a residential board and care facility. (SAF-BCF)

**3.3.234 Residential Occupancy.** See 3.3.190.13.

**3.3.235 Safe Location.** A location remote or separated from the effects of a fire so that such effects no longer pose a threat. (SAF-FUN)

**3.3.236 Safety Factor.** A factor applied to a predicted value to ensure that a sufficient safety margin is maintained. (SAF-FUN)

**3.3.237 Safety Margin.** The difference between a predicted value and the actual value where a fault condition is expected. (SAF-FUN)

**3.3.238 Sally Port (Security Vestibule).** A compartment provided with two or more doors where the intended purpose is to prevent continuous and unobstructed passage by allowing the release of only one door at a time. (SAF-DET)

**3.3.239 Seating.**

**3.3.239.1\* Festival Seating.** A form of audience/spectator accommodation in which no seating, other than a floor or finished ground level, is provided for the audience/spectators gathered to observe a performance. (SAF-AXM)

**A.3.3.239.1 Festival Seating.** Festival seating describes situations in assembly occupancies where live entertainment events are held that are expected to result in overcrowding and high audience density that can compromise public safety. It is not the intent to apply the term *festival seating* to exhibitions; sports events; dances; conventions; and bona fide political, religious, and educational events. Assembly occupancies with 15 ft<sup>2</sup> (1.4 m<sup>2</sup>) or more per person should not be considered festival seating.

Exhibit 3.32 illustrates the form of standup audience viewing area called festival seating at a nightclub featuring live entertainment.

Exhibit 3.32

Festival seating.

**3.3.239.2 Fixed Seating.** Seating that is secured to the building structure. (SAF-AXM)

**3.3.239.3 Folding and Telescopic Seating.** A structure that is used for tiered seating of persons and whose overall shape and size can be reduced, without being dismantled, for purposes of moving or storing. (SAF-AXM)

**3.3.239.4 Smoke-Protected Assembly Seating.** Seating served by means of egress that is not subject to smoke accumulation within or under the structure. (SAF-AXM)

Exhibit 3.33

Door leaf with self-closing hardware.

**3.3.240 Self-Closing.** Equipped with an approved device that ensures closing after opening. (SAF-MEA)

Exhibit 3.33 illustrates self-closing hardware on a door leaf of a door assembly. The self-closer in this case takes the form of a hydraulic arm. Doors might also be made self-closing via the provision of spring hinges.

**3.3.241\* Self-Luminous.** Illuminated by a self-contained power source and operated independently of external power sources. (SAF-MEA)

**A.3.3.241 Self-Luminous.** An example of a self-contained power source is tritium gas. Batteries do not qualify as a self-contained power source. The light source is typically contained inside the device.

**3.3.242\* Self-Preservation (Day-Care Occupancy).** The ability of a client to evacuate a day-care occupancy without direct intervention by a staff member. (SAF-END)

**A.3.3.242 Self-Preservation (Day-Care Occupancy).** Examples of clients who are incapable of self-preservation include infants, clients who are unable to use stairs because of confinement to a wheelchair or other physical disability, and clients who cannot follow directions or a group to the outside of a facility due to mental or behavioral disorders. It is the intent of this *Code* to classify children under the age of 24 months as incapable of self-preservation. Examples of direct intervention by staff members include carrying a client, pushing a client outside in a wheelchair, and guiding a client by direct hand-holding or continued bodily contact. If clients cannot exit the building by themselves with minimal intervention from staff members, such as verbal orders, classification as incapable of self-preservation should be considered.

**3.3.243 Sensitivity Analysis.** See 3.3.17.1.

**3.3.244 Separate Atmosphere.** See 3.3.26.2.

**3.3.245 Separated Occupancy.** See 3.3.190.14.

**3.3.246 Severe Mobility Impairment.** The ability to move to stairs but without the ability to use the stairs. (SAF-MEA)

**3.3.247 Single Station Alarm.** See 3.3.14.1.

**3.3.248 Site-Fabricated Stretch System.** See 3.3.274.2.

**3.3.249\* Situation Awareness.** The perception of the elements in the environment within a volume of time and space, the comprehension of their meaning, and the projection of their status in the near future. (SAF-FUN)

**A.3.3.249 Situation Awareness.** Situation awareness (also called situational awareness), described in a simpler fashion, is being aware of what is happening around you and understanding what that information means to you now and in the future. This definition, and the more formal definition, come from the extensive work of human factors (ergonomics) experts in situation awareness, most notably Mica R. Endsley (Endsley, Bolte and Jones, *Designing for Situation Awareness: An approach to user-centered design*, CRC Press, Taylor and Francis, Boca Raton, FL, 2003). Within the *Code*, and the standards it references, are long-standing requirements for systems and facilities that enhance situation awareness. Included are fire/smoke detection, alarm, and communication systems plus the system status panels in emergency command centers; supervisory systems for various especially critical components (e.g., certain valves) of fire protection systems; waterflow indicators; certain signs; and the availability of trained staff, notably in health care occupancies. Serious failures of situation awareness have been identified as central to unfortunate outcomes in various emergencies; for example, typical responses of people to developing fires also exhibit situation awareness problems as incorrect assumptions are made about the rapidity of fire growth or the effect of opening a door. Good situation awareness is critical to decision making, which, in turn, is critical to performance during an emergency.

The definition of the term *situation awareness* helps to support the criteria of 4.5.5, which include situation awareness in the fundamental requirements of Section 4.5. See 4.5.5 and A.4.5.5 for examples of systems that are currently required by the *Code* and that help to provide situation awareness.

**3.3.250 Slow Evacuation Capability.** See 3.3.78.3.

**3.3.251 Smoke Alarm.** See 3.3.14.2.

**3.3.252 Smoke Barrier.** See 3.3.31.2.

**3.3.253 Smoke Compartment.** See 3.3.48.2.

**3.3.254 Smoke Detector.** A device that detects visible or invisible particles of combustion. [72, 2013] (SAF-BSF)

**3.3.255 Smoke Developed Index.** See 3.3.149.2.

**3.3.256\* Smoke Partition.** A continuous membrane that is designed to form a barrier to limit the transfer of smoke. (SAF-FIR)

**A.3.3.256 Smoke Partition.** A smoke partition is not required to have a fire resistance rating.

**3.3.257\* Smokeproof Enclosure.** An enclosure designed to limit the movement of products of combustion produced by a fire. (SAF-MEA)

**A.3.3.257 Smokeproof Enclosure.** For further guidance, see the following publications:

- (1) ASHRAE *Handbook and Product Directory — Fundamentals*
- (2) *Principles of Smoke Management*, by Klote and Milke
- (3) NFPA 105, *Standard for Smoke Door Assemblies and Other Opening Protectives*

**3.3.258 Smoke-Protected Assembly Seating.** See [3.3.239.4](#).

**3.3.259 Special Amusement Building.** See [3.3.36.10](#).

**3.3.260 Special Inspection.** Services provided by a qualified person, retained by the owner and approved by the authority having jurisdiction, who observes the installation and witnesses the pretesting and operation of the system or systems. (SAF-BSF)

**3.3.261 Special-Purpose Industrial Occupancy.** See [3.3.190.8.3](#).

### 3.3.262 Specification.

**3.3.262.1\* Design Specification.** A building characteristic and other conditions that are under the control of the design team. (SAF-FUN)

**A.3.3.262.1 Design Specification.** Design specifications include both hardware and human factors, such as the conditions produced by maintenance and training. For purposes of performance-based design, the design specifications of interest are those that affect the ability of the building to meet the stated goals and objectives.

**3.3.262.2 Input Data Specification.** Information required by the verification method. (SAF-FUN)

**3.3.263 Staff (Residential Board and Care).** Persons who provide personal care services, supervision, or assistance. (SAF-BCF)

**3.3.264 Stage.** A space within a building used for entertainment and utilizing drops or scenery or other stage effects. (SAF-AXM)

**3.3.264.1 Legitimate Stage.** A stage with a height greater than 50 ft (15 m) measured from the lowest point on the stage floor to the highest point of the roof or floor deck above. (SAF-AXM)

**3.3.264.2 Regular Stage.** A stage with a height of 50 ft (15 m) or less measured from the lowest point on the stage floor to the highest point of the roof or floor deck above. (SAF-AXM)

### 3.3.265\* Stair.

**A.3.3.265 Stair.** See [7.2.2.6](#).

**3.3.265.1 Aisle Stair.** A stair within a seating area of an assembly occupancy that directly serves rows of seats to the side of the stair, including transition stairs that connect to an aisle or a landing. (SAF-AXM)

The definition of the term *aisle stair* was revised for the 2015 edition of the *Code* to include transition stairs. The change helps to support the new criteria of [12.2.5.6.8](#) and [13.2.5.6.8](#) relative to aisle landings.

**3.3.265.2 Outside Stair.** A stair with not less than one side open to the outer air. (SAF-MEA)

**3.3.266 Stakeholder.** An individual, or representative of same, having an interest in the successful completion of a project. (SAF-FUN)

**3.3.267 Storage Occupancy.** See [3.3.190.15](#).

**3.3.268\* Stories in Height.** The story count starting with the level of exit discharge and ending with the highest occupiable story containing the occupancy considered. (SAF-FUN)

**A.3.3.268 Stories in Height.** Stories below the level of exit discharge are not counted as stories for determining the stories in height of a building.

**3.3.269\* Story.** The portion of a building located between the upper surface of a floor and the upper surface of the floor or roof next above. (SAF-FUN)

**A.3.3.269 Story.** Stories used exclusively for mechanical equipment rooms, elevator penthouses, and similar spaces are not occupiable stories.

**3.3.269.1 Occupiable Story.** A story occupied by people on a regular basis. (SAF-FUN)

**3.3.270 Street.** A public thoroughfare that has been dedicated for vehicular use by the public and can be used for access by fire department vehicles. (SAF-MEA)

**3.3.271\* Street Floor.** A story or floor level accessible from the street or from outside the building at the finished ground level, with the floor level at the main entrance located not more than three risers above or below the finished ground level, and arranged and utilized to qualify as the main floor. (SAF-MER)

**A.3.3.271 Street Floor.** Where, due to differences in street levels, two or more stories are accessible from the street, each is a street floor. Where there is no floor level within the specified

limits for a street floor above or below the finished ground level, the building has no street floor.

**3.3.272\* Structure.** That which is built or constructed. (SAF-FUN)

**A.3.3.272 Structure.** The term *structure* is to be understood as if followed by the words *or portion thereof*. (See also *Building*, A.3.3.36.)

**3.3.272.1 Air-Inflated Structure.** A structure whose shape is maintained by air pressure in cells or tubes forming all or part of the enclosure of the usable area and in which the occupants are not within the pressurized area used to support the structure. (SAF-IND)

**3.3.272.2\* Air-Supported Structure.** A structure where shape is maintained by air pressure and in which occupants are within the elevated pressure area. (SAF-IND)

**A.3.3.272.2 Air-Supported Structure.** A cable-restrained air-supported structure is one in which the uplift is resisted by cables or webbing that is anchored by various methods to the membrane or that might be an integral part of the membrane. An air-supported structure is not a tensioned-membrane structure.

**3.3.272.3 Limited Access Structure.** A structure or portion of a structure lacking emergency openings. (SAF-IND)

**3.3.272.4 Membrane Structure.** A building or portion of a building incorporating an air-inflated, air-supported, tensioned-membrane structure; a membrane roof; or a membrane-covered rigid frame to protect habitable or usable space. (SAF-IND)

**3.3.272.5 Multilevel Play Structure.** A structure that consists of tubes, slides, crawling areas, and jumping areas that is located within a building and is used for climbing and entertainment, generally by children. (SAF-AXM)

**3.3.272.6\* Open Structure.** A structure that supports equipment and operations not enclosed within building walls. (SAF-IND)

**A.3.3.272.6 Open Structure.** Open structures are often found in oil refining, chemical processing, or power plants. Roofs or canopies without enclosing walls are not considered an enclosure.

**3.3.272.7\* Parking Structure.** A building, structure, or portion thereof used for the parking, storage, or both, of motor vehicles. [88A, 2015] (SAF-IND)

The definitions of 3.3.272.7 through 3.3.272.7.5, for parking structures are extracted from NFPA 88A, *Standard for Parking Structures*,<sup>4</sup> and are identified as “preferred” in the *NFPA Glossary of Terms*. See the commentary that follows the title of Section 3.3, which discusses the glossary. The parking structure definitions help to support the provisions of Section 42.8.

Exhibit 3.34 illustrates a parking structure.

**A.3.3.272.7 Parking Structure.** A parking structure is permitted to be enclosed or open, use ramps, and use mechanical

Exhibit 3.34

Parking structure.

control push-button-type elevators to transfer vehicles from one floor to another. Motor vehicles are permitted to be parked by the driver or an attendant or are permitted to be parked mechanically by automated facilities. Where automated-type parking is provided, the operator of those facilities is permitted either to remain at the entry level or to travel to another level. Motor fuel is permitted to be dispensed, and motor vehicles are permitted to be serviced in a parking structure in accordance with NFPA 30A. [88A, 2015]

**3.3.272.7.1 Assisted Mechanical Type Parking Structure.** A parking structure that uses lifts or other mechanical devices to transport vehicles to the floors of a parking structure, where the vehicles are then parked by a person. [88A, 2015] (SAF-IND)

**3.3.272.7.2 Automated Type Parking Structure.** A parking structure that uses computer controlled machines to store and retrieve vehicles, without drivers, in multi-level storage racks with no floors. [88A, 2015] (SAF-IND)

**3.3.272.7.3 Enclosed Parking Structure.** Any parking structure that is not an open parking structure. [88A, 2015] (SAF-IND)

**3.3.272.7.4 Open Parking Structure.** A parking structure that meets the requirements of 42.8.1.3 (SAF-IND).

**3.3.272.7.5 Ramp Type Parking Structure.** A parking structure that utilizes sloped floors for vertical vehicle circulation. [88A, 2015] (SAF-IND)

**3.3.272.8 Permanent Structure.** A building or structure that is intended to remain in place for a period of more than 180 days in any consecutive 12-month period. (SAF-FUN)

**3.3.272.9 Temporary Structure.** A building or structure not meeting the definition of *permanent structure*. (See also 3.3.272.8, *Permanent Structure*.) (SAF-FUN)

**3.3.272.10 Tensioned-Membrane Structure.** A membrane structure incorporating a membrane and a structural support system such as arches, columns and cables, or beams wherein the stresses developed in the tensioned membrane interact with those in the structural support so that the entire assembly acts together to resist the applied loads. (SAF-IND)

**3.3.272.11\* Underground Structure.** A structure or portions of a structure in which the floor level is below the level of exit discharge. (SAF-IND)

**A.3.3.272.11 Underground Structure.** In determining openings in exterior walls, doors or access panels are permitted to be included. Windows are also permitted to be included, provided that they are openable or provide a breakable glazed area.

**3.3.272.12 Water-Surrounded Structure.** A structure fully surrounded by water. (SAF-IND)

### 3.3.273 Suite.

**3.3.273.1 Guest Suite.** An accommodation with two or more contiguous rooms comprising a compartment, with or without doors between such rooms, that provides living, sleeping, sanitary, and storage facilities. (SAF-RES)

**3.3.273.2 Non-Patient-Care Suite (Health Care Occupancies).** A suite within a health care occupancy that is not intended for sleeping or treating patients. (SAF-HEA)

The definition of the term *non-patient-care suite* helps to clarify that health care occupancy non-patient-care suites are treated differently than patient care suites in Chapters 18 and 19. See 18.2.5.7 and 19.2.5.7.

**3.3.273.3 Patient Care Non-Sleeping Suite (Health Care Occupancies).** A suite for treating patients with or without patient beds not intended for overnight sleeping. (SAF-HEA)

Exhibit 3.35 illustrates the entrance to a health care occupancy hospital emergency room suite. The suite is an example of a patient care non-sleeping suite.

**3.3.273.4 Patient Care Sleeping Suite (Health Care Occupancies).** A suite containing one or more patient beds intended for overnight sleeping. (SAF-HEA)

**3.3.273.5 Patient Care Suite (Health Care Occupancies).** A series of rooms or spaces or a subdivided room separated from the remainder of the building by walls and doors. (SAF-HEA)

### 3.3.274 System.

**3.3.274.1 Elevator Evacuation System.** A system, including a vertical series of elevator lobbies and associated elevator lobby doors, an elevator shaft(s), and a machine room(s), that provides protection from fire effects for elevator passengers, people waiting to use elevators, and elevator equipment so that elevators can be used safely for egress. (SAF-MEA)

Exhibit 3.35

Patient care non-sleeping suite.

**3.3.274.2 Site-Fabricated Stretch System.** A system, fabricated on-site, and intended for acoustical, tackable, or aesthetic purposes, that is comprised of three elements: (1) a frame (constructed of plastic, wood, metal, or other material) used to hold fabric in place, (2) a core material (infill, with the correct properties for the application), and (3) an outside layer, comprised of a textile, fabric, or vinyl, that is stretched taut and held in place by tension or mechanical fasteners via the frame. (SAF-INT)

**3.3.275 Technically Infeasible.** A change to a building that has little likelihood of being accomplished because the existing structural conditions require the removal or alteration of a load-bearing member that is an essential part of the structural frame, or because other existing physical or site constraints prohibit modification or addition of elements, spaces, or features that are in full and strict compliance with applicable requirements. (SAF-FUN)

**3.3.276 Temporary Platform.** See 3.3.211.1.

**3.3.277 Temporary Structure.** See 3.3.272.9.

**3.3.278 Tensioned-Membrane Structure.** See 3.3.272.10.

**3.3.279\* Tent.** A temporary structure, the covering of which is made of pliable material that achieves its support by mechanical means such as beams, columns, poles, or arches, or by rope or cables, or both. (SAF-IND)

**A.3.3.279 Tent.** A tent might also include a temporary tensioned-membrane structure.

**3.3.279.1 Private Party Tent.** A tent erected in the yard of a private residence for entertainment, recreation, dining, a reception, or similar function. (SAF-AXM)

**3.3.280 Thermal Barrier.** See 3.3.31.3.

**3.3.281 Tower.** An enclosed independent structure or portion of a building with elevated levels for support of equipment or occupied for observation, control, operation, signaling, or similar limited use. (SAF-IND)

**3.3.281.1 Air Traffic Control Tower.** An enclosed structure or building at airports with elevated levels for support of equipment and occupied for observation, control, operation, and signaling of aircraft in flight and on the ground. (SAF-IND)

The definition of the term *air traffic control tower* helps to support the criteria of 11.3.4, which impose on air traffic control towers requirements that exceed those for other towers addressed by Section 11.3.

Exhibit 3.36 depicts the air traffic control tower at Denver International Airport, Denver, Colorado.

Exhibit 3.36

Air traffic control tower at Denver International Airport. (Courtesy of Denver International Airport)

**3.3.282 Two-Family Dwelling Unit.** See 3.3.66.3.

**3.3.283 Uncertainty Analysis.** See 3.3.17.2.

**3.3.284 Underground Structure.** See 3.3.272.11.

**3.3.285 Verification Method.** A procedure or process used to demonstrate or confirm that the proposed design meets the specified criteria. (SAF-FUN)

**3.3.286\* Vertical Opening.** An opening through a floor or roof. (SAF-FIR)

**A.3.3.286 Vertical Opening.** Vertical openings might include items such as stairways; hoistways for elevators, dumbwaiters, and inclined and vertical conveyors; shaftways used for light, ventilation, or building services; or expansion joints and seismic joints used to allow structural movements.

**3.3.287 Vomitory.** An entrance to a means of egress from an assembly seating area that pierces the seating rows. (SAF-AXM)

Exhibit 3.37 illustrates a vomitory or portal used for occupants to move from the tiered seating area in the stadium to the concourse level along the egress route to the exit discharge.

Exhibit 3.37

Vomitory or portal connecting seating area to the concourse. (© Martin Applegate, Dreamstime.com)

**3.3.288 Wall.**

**3.3.288.1 Fire Barrier Wall.** A wall, other than a fire wall, that has a fire resistance rating. (SAF-FIR)

**3.3.288.2 Proscenium Wall.** The wall that separates the stage from the auditorium or house. (SAF-AXM)

**3.3.289\* Wall or Ceiling Covering.** A textile-, paper-, or polymeric-based product designed to be attached to a wall or ceiling surface for decorative or acoustical purposes. (SAF-INT)

**A.3.3.289 Wall or Ceiling Covering.** Wall or ceiling coverings with ink or top coat layers added as part of the manufacturing process are included in this definition. The term “polymeric” is intended to include “vinyl.”

**3.3.290 Water-Surrounded Structure.** See 3.3.272.12.

**3.3.291 Weathered-Membrane Material.** See 3.3.171.5.

**3.3.292 Yard.** An open, unoccupied space other than a court, unobstructed from the finished ground level to the sky on the lot on which a building is situated. (SAF-MEA)

# General

**Chapter 1** contains general administration provisions, including scope, title, purpose, application, equivalency, units and formulas, and enforcement. **Chapter 4** contains all remaining general *Code* provisions.

Within **Chapter 4**, **Sections 4.1**, **4.2**, and **4.3** address goals, objectives, and assumptions and apply to prescriptive-based and performance-based life safety designs.

**Section 4.4** offers building designers and owners the prerogative of following the prescriptive requirements of the *Code* or developing an acceptable performance-based design in accordance with **Chapter 5** and in careful consultation with the authority having jurisdiction (AHJ).

**Section 4.5** includes fundamental requirements that present a qualitative summary of what the other specific requirements, in total, are supposed to achieve.

Portions of **Section 4.6** present the philosophy associated with enforcement of the *Code* — namely, who enforces it and when it applies to special conditions. **Paragraph 4.6.9.2** mandates a warrant of fitness for buildings that have utilized the performance-based option. The warrant of fitness verifies for the AHJ that the terms and conditions that were part of the performance-based design have not been modified to the point that the building is unsafe.

**Section 4.6** also serves as the repository for a variety of general provisions that have applicability to requirements in one or more of the chapters of the *Code*. For example, **4.6.3** addresses what is meant where the term *stories in height* is used anywhere in the *Code*. Similarly, **4.6.13** and **4.6.14** address what is meant where the term *noncombustible material* or the term *limited-combustible material* is used anywhere in the *Code*.

**Section 4.7** presents the operational details associated with emergency egress and relocation drills.

**Section 4.8** rounds out the chapter by presenting emergency action plan requirements.

---

## 4.1\* Goals

**A.4.1** The goals in **Section 4.1** reflect the scope of this *Code* (see **Section 1.1**). Other fire safety goals that are outside the scope of this *Code* might also need to be considered, such as property protection and continuity of operations. Compliance with this *Code* can assist in meeting goals outside the scope of the *Code*.

The goals in **Section 4.1** apply regardless of whether the prescriptive-based option of **4.4.1(1)** and **4.4.2** or the

performance-based option of **4.4.1(2)** and **4.4.3** is used. For prescriptive-based life safety systems, compliance with the specifications of **Chapter 4** and **Chapters 6** through **43** provides a level of life safety that meets the goals of **Section 4.1**. For performance-based life safety systems, compliance with the goals needs to be demonstrated in the required documentation package, with consideration given not only to the goals but also to the objectives (see **Section 4.2**) and performance criteria (see **Section 5.2**) associated with specific design fire scenarios (see **Section 5.5**).

**4.1.1\* Fire.** A goal of this *Code* is to provide an environment for the occupants that is reasonably safe from fire by the following means:

- (1)\* Protection of occupants not intimate with the initial fire development
- (2) Improvement of the survivability of occupants intimate with the initial fire development

**A.4.1.1** Reasonable safety risk is further defined by subsequent language in this *Code*.

**A.4.1.1(1)** The phrase “intimate with the initial fire development” refers to the person(s) at the ignition source or first materials burning, not to all persons within the same room or area.

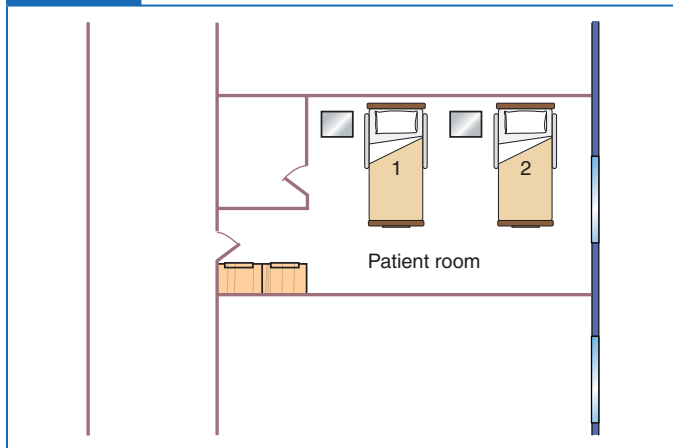

The example that follows illustrates the level of safety intended by compliance with the requirement of **4.1.1(1)** to protect occupants not intimate with initial fire development.

### **Example: Protection of Occupants Not Intimate with Initial Fire Development**

Consider a two-person patient sleeping room in a hospital, such as the one shown in **Exhibit 4.1**. One patient, Patient 1, occupies a bed near the room door to the corridor. The other patient, Patient 2, occupies a bed near the outside wall with a window.

Assume that Patient 1 is smoking in bed, contrary to hospital policy, and ignites her sleeping gown and bedding. Patient 1 is considered to be intimate with initial fire development. Patient 2 is located approximately 48 in. (1220 mm) from Patient 1 and is not considered intimate with initial fire development. To meet the goal of **4.1.1(1)**, the prescriptive requirements applicable to hospitals via the health care occupancy provisions of **Chapters 18** and **19** work together to save the life of Patient 2. Note that Patient 2’s egress route involves passing the fire in Patient 1’s bed. Therefore, the applicable *Code* requirements combine a host of building features, systems, and staff actions to save Patient 2. In doing so, the level of safety offered to Patient 2

Exhibit 4.1

Protection of occupant not intimate with initial fire development.

has the effect required by 4.1.1(2) of improving the survivability of Patient 1, who is intimate with initial fire development. Compliance with 4.1.1(2) is more a consequence of having met 4.1.1(1), rather than a deliberate protection scheme.

**4.1.2\* Comparable Emergencies.** An additional goal is to provide life safety during emergencies that can be mitigated using methods comparable to those used in case of fire.

**A.4.1.2** “Comparable emergencies” refers to incidents where the hazard involves thermal attributes similar to fires or airborne contaminants similar to smoke, such that features mandated by this Code can be expected to mitigate the hazard. Examples of such incidents might be explosions and hazardous material releases. The Code recognizes that features mandated by this Code might be less effective against such hazards than against fires.

The provision of 4.1.1 in the 2006 edition of the Code was titled Fire and Similar Emergency. In the 2009 edition, the provision was split into 4.1.1, Fire, and 4.1.2, Comparable Emergencies, as the term *similar emergencies* was not explained. The text of 4.1.2 and A.4.1.2 clarifies the subject; provides examples of comparable emergencies; and recognizes that features required by the Code might not be as effective in mitigating such hazards, as the Code's primary focus is protection against fire.

**4.1.3\* Crowd Movement.** An additional goal is to provide for reasonably safe emergency crowd movement and, where required, reasonably safe nonemergency crowd movement.

**A.4.1.3** An assembly occupancy is an example of an occupancy where the goal of providing for reasonably safe emergency and nonemergency crowd movement has applicability. A detention or correctional occupancy is an example of an occupancy where emergency and nonemergency crowd movement is better addressed by detention and correctional facilities specialists than by this Code.

An example of a requirement for nonemergency crowd movement appears in 12.2.5.4.3 and 13.2.5.4.3, which apply to assembly occupancies, where access and egress routes are required to be maintained so that crowd management, security, and emergency medical personnel are able to move to any individual at any time without undue hindrance. However, almost all other occupancy chapters remain silent on the subject of nonemergency crowd movement — some because the committee has made a conscious decision to omit such information, and others because the subject has not been discussed at technical committee meetings. For example, the detention and correctional occupancies chapters deliberately remain silent on the subject because professionals who are involved in the daily operation of such facilities are best qualified to address the movement of residents in occupancies where security concerns are paramount. It is important to note that, per the purpose statement in Section 1.2, the minimum requirements of this Code were developed with due regard for function. The Code endeavors to avoid requirements that might interfere with the normal use and occupancy of a building.

## 4.2 Objectives

As in the case of application of the goals of Section 4.1, the objectives of Section 4.2 apply regardless of whether the prescriptive-based option of 4.4.1(1) and 4.4.2 or the performance-based option of 4.4.1(2) and 4.4.3 is used. For prescriptive-based life safety systems, compliance with the specifications of Chapter 4 and Chapters 6 through 43 provides a level of life safety that meets the objectives of Section 4.2. For performance-based life safety systems, compliance with the objectives needs to be demonstrated in the required documentation, with consideration given not only to the objectives but also to the goals (see Section 4.1) and performance criteria (see Section 5.2) associated with specific design fire scenarios (see Section 5.5).

The objectives present requirements that must be satisfied to achieve the goals of Section 4.1. Objectives are stated in more specific terms than goals and tend to be more quantitative than qualitative. The goals of Section 4.1 are general enough to apply to numerous NFPA documents. The objectives of Section 4.2 are more specific to the *Life Safety Code* itself. Goals and objectives, taken together, form the initial targets at which a performance-based life safety system can take aim. The goals and objectives alone do not provide sufficient detail to develop and measure the performance of a design. Rather, the performance criteria and other elements of Chapter 5, Performance-Based Option, are needed to flesh out the subject in sufficient detail.

**4.2.1 Occupant Protection.** A structure shall be designed, constructed, and maintained to protect occupants who are not intimate with the initial fire development for the time needed to evacuate, relocate, or defend in place.

**4.2.2 Structural Integrity.** Structural integrity shall be maintained for the time needed to evacuate, relocate, or defend in place occupants who are not intimate with the initial fire development.

The *Code* is not a building code. However, in certain occupancy chapters, minimum construction requirements are presented in the \_\_.1.6 subsection to help maintain structural integrity for the time needed for evacuation. For example, assembly occupancies with large occupant loads on stories other than the level of exit discharge might require long time periods to fully evacuate the building. The provisions of 12.1.6 and 13.1.6 require such assembly occupancy buildings to be of fire resistance-rated construction to help guarantee that the building will not collapse prior to the completion of the evacuation process. Similarly, Chapters 18 and 19 for health care occupancies regulate building construction type because they employ a protect-in-place strategy that minimizes the need to evacuate patients/residents in recognition of the fact that the movement of such patients/residents can be harmful to them. Contrast the examples of the assembly and health care occupancies with those of educational occupancies as addressed in Chapters 14 and 15. It is expected that occupants of an educational occupancy building will evacuate quickly so that the provisions of 14.1.6 and 15.1.6 do not need to regulate building construction type for compliance with 4.2.2.

**4.2.3 Systems Effectiveness.** Systems utilized to achieve the goals of Section 4.1 shall be effective in mitigating the hazard or condition for which they are being used, shall be reliable, shall be maintained to the level at which they were designed to operate, and shall remain operational.

---

### 4.3\* Assumptions

**A.4.3** Additional assumptions that need to be identified for a performance-based design are addressed in Chapter 5.

**4.3.1\* General.** The protection methods of this *Code* are based on the hazards associated with fire and other events that have comparable impact on a building and its occupants.

**A.4.3.1** Protection against certain terrorist acts will generally require protection methods beyond those required by this *Code*.

**4.3.2 Single Fire Source.** The fire protection methods of this *Code* assume a single fire source.

The protection methods referenced in 4.3.1 are expressed in the requirements applicable to any given occupancy. The committees on safety to life have traditionally discussed proposed *Code* changes in the context of mitigating the hazards associated with fire. Given that Section 4.1 splits out the goals associated with fire from those associated with comparable emergencies, the technical committees evaluate changes based on protection from fire and comparable emergencies.

The text of A.4.3.1 advises that the *Code* does not prescribe protection methods against certain terrorist acts. Society's behavior might have changed following the September 11, 2001, collapse of the World Trade Center towers in New York City, as evidenced by the reluctance of occupants of high-rise buildings to stay behind at the first hint of fire or similar problem. Yet, society has not demanded, for example, that unlimited resources be expended to make a high-rise building immune to a direct strike by an airliner. It is not practical to protect against all terrorist acts.

For the user of the traditional, prescriptive, specification-based requirements, the single fire source assumption of 4.3.2 is a piece of explanatory material and not a requirement. The assumption explains that the *Code* authors developed the requirements with the challenge of a single fire source in mind. Thus, most occupancy chapters require a minimum of two means of egress; if the single fire blocks one, then the other should be available for egress. Had the *Code* been written to protect against fires that begin in two locations, then it probably would be common to find occupancy chapter requirements for a minimum of three means of egress, even for small buildings with small occupant loads. Historically, the *Code's* approach to protecting against a single-source fire has proved to meet society's expectations.

---

## 4.4 Life Safety Compliance Options

**4.4.1 Options.** Life safety meeting the goals and objectives of Sections 4.1 and 4.2 shall be provided in accordance with either of the following:

- (1) Prescriptive-based provisions per 4.4.2
- (2) Performance-based provisions per 4.4.3

*Code* editions prior to 2000 required compliance with the prescriptive, specification-based requirements and offered some additional design flexibility via the equivalency concept contained in Section 1.4. Editions since 2000 offer the option of designing the life safety systems using an *in toto* performance-based approach. Both the prescriptive-based and performance-based options are tied to the goals and objectives of Sections 4.1 and 4.2, respectively.

The prescriptive-based and performance-based options are offered as equivalents, with neither option designated as the preferred method. Given that performance-based design is unfamiliar to most *Code* users, and that it is complicated to use, most traditional buildings will probably continue to be designed and built to comply with the prescriptive requirements. The performance-based approach will be reserved for use on large, complicated structures where the additional costs associated with such a design can be offset by savings on prescriptive features that can be omitted from the design. The performance-based option also is to be used for innovative designs that are

likely to be prohibited by the prescriptive requirements. For example, before 1981, when atria were first specifically addressed in the *Code*, a designer proposing to build an atrium building would likely have been challenged by the authority having jurisdiction, who might view the atrium as a hole in the building's floors through which smoke and other products of combustion could be spread. In the 1981 and subsequent editions of the *Code*, the inclusion of provisions for atria showed that, with full building sprinkler and smoke control systems, the atrium could be turned into a fire and life safety asset — one that serves as a smoke dispersion and accumulation chamber early in the fire, so as to allow exit access through the atrium. The performance-based approach offers a host of new tools that are used to prove the efficacy of unique designs and unusual, functionally dictated space arrangements.

#### 4.4.2 Prescriptive-Based Option.

**4.4.2.1** A prescriptive-based life safety design shall be in accordance with **Chapters 1** through **4**, **Chapters 6** through **11**, **Chapter 43**, and the applicable occupancy chapter, **Chapters 12** through **42**.

A prescriptive-based life safety design is the traditional norm. Each applicable requirement is met individually, and the resultant level of life safety is deemed to meet the goals and objectives of **Sections 4.1** and **4.2**, respectively. The requirements are chosen, depending on occupancy classification, from a wide host of possible *Code* chapters, namely, any and all chapters except **Chapter 5**, Performance-Based Option.

**4.4.2.2** Prescriptive-based designs meeting the requirements of **Chapters 1** through **3**, **Sections 4.5** through **4.8**, and **Chapters 6** through **43** of this *Code* shall be deemed to satisfy the provisions of **Sections 4.1** and **4.2**.

**4.4.2.3** Where a requirement of this *Code* conflicts with another requirement of this *Code*, the following shall apply:

- (1)\* Where a specific requirement contained in **Chapters 11** through **43** conflicts with a general requirement contained in **Chapters 1** through **4** and **Chapters 6** through **10**, the requirement of **Chapters 11** through **43** shall govern.
- (2)\* Where a requirement contained in **Chapters 1** through **4** and **Chapters 6** through **10** conflicts with another requirement contained in **Chapters 1** through **4** and **Chapters 6** through **10**, the more specific requirement shall govern.
- (3)\* Where a requirement contained in **Chapters 11** through **43** conflicts with another requirement contained in **Chapters 11** through **43**, the more specific requirement shall govern.

**A.4.4.2.3(1)** As an example, **Table 7.2.2.2.1.1(a)** limits a new stair to having a maximum riser height of 7 in. (180 mm) and **12.2.5.6.6** limits a new aisle stair in an assembly occupancy to having a maximum riser height of 8 in. (205 mm), 9 in. (230 mm), or 11 in. (280 mm). The specific provisions of **12.2.5.6.6** are

intended to govern the maximum riser height for the new aisle stairs in assembly occupancies, not the general riser height requirement of **Table 7.2.2.2.1.1(a)**.

**A.4.4.2.3(2)** As an example, **7.1.3.2.1** requires an exit stair to be enclosed and separated from the remainder of the building by fire resistance-rated construction of at least one hour and **8.6.5** requires a minimum fire resistance rating of ½ hour for the enclosure of an existing floor opening. A existing hole in a floor used for a stair creates a vertical opening subject to the enclosure and protection requirements of **8.6.5**. Where such stair is used as an exit stair, it is subject to the requirements of **7.1.3.2.1** for the separation and enclosure of exits. The case of a stair used as an exit stair is more specific than the case of a non-exit stair that creates a vertical opening. The provision of **7.1.3.2.1** governs with respect to the required fire resistance rating of the exit stair enclosure.

**A.4.4.2.3(3)** As an example, the provision of **11.8.2.2** that prohibits elevator lobby door locking in new high-rise buildings is more specific than the provision of **38.2.2.2.3** that permits elevator lobby exit access door-locking arrangements in accordance with **7.2.1.6.3** in new business occupancies. New high-rise business occupancy buildings are a specific subset of the general category of new business occupancy buildings. Extra provisions and limitations are mandated for new high-rise business occupancy buildings that are not mandated for new non-high-rise business occupancy buildings. The specific provision of **11.8.2.2** is intended to govern the locking of elevator lobby doors, not the general provision of **38.2.2.2.3**.

The provisions of **4.4.2.3(2)** and **4.4.2.3(3)** are new to the 2015 edition of the *Code*. They help to complete the package of provisions, beginning with **4.4.2.3(1)**, relative to determining which requirement takes precedence when conflicts exist within the *Code*. The *Life Safety Code* is formatted such that **Chapters 1** through **4** and **Chapters 6** through **10** contain administrative provisions and fundamental requirements establishing minimum acceptable criteria for all types of occupancies. **Chapters 12** through **42** of the *Code* establish criteria for life safety based on the characteristic needs of specific occupancies. **Chapter 11** further modifies the occupancy chapter provisions if unusual situations exist or the building is a limited access (e.g., windowless), underground, or high-rise building. **Chapter 43** on existing building rehabilitation was added to the *Code* in 2006 and serves the dual role of being a core chapter and a chapter that has requirements specific to certain occupancies.

Where requirements differ between the general provisions of **Chapters 1** through **4** and **Chapters 6** through **10** and the more specific provisions of **Chapters 11** through **43**, **4.4.2.3(1)** advises that the requirements contained in **Chapters 11** through **43** take precedence. The new text of **4.4.2.3(2)** and **4.4.2.3(3)** addresses two other ways in which *Code* requirements might conflict with each other. The annex text of **A.4.4.2.3(1)**, **A.4.4.2.3(2)**, and **A.4.4.2.3(3)** provides examples of each of these forms of conflicts.

To avoid conflicts, if an occupancy chapter exempts itself from a requirement of a core chapter, the core chapter will usually specify that the deviation from the requirement is permitted. For example, although 7.2.2.3.3.1 requires treads of stairs and landing surfaces to be solid, 7.2.2.3.3.5 permits noncombustible grated stair treads and landings in various specified occupancies, including industrial occupancies as provided in Chapter 40. Paragraph 40.2.2.3.1(1) confirms the exemption for noncombustible grated stair treads and landings in industrial occupancies.

**4.4.3 Performance-Based Option.** A performance-based life safety design shall be in accordance with Chapters 1 through 5.

A performance-based life safety design is exempt from the myriad prescriptive, specification-based requirements of the Code but must meet the administrative and general requirements of Chapters 1 through 4. The design must adhere to the definitions of Chapter 3 so that the authority having jurisdiction that judges the performance of the design can communicate with the designer in terminology that is common to all Code users. More important, the performance-based design must meet the provisions contained in Chapter 5, Performance-Based Option. Chapter 5 contains a limited number of prescriptive provisions that have been retained from Chapter 7, Means of Egress, for applicability to the performance-based design. See Section 5.3.

## 4.5 Fundamental Requirements

Section 4.5 outlines the fundamental concepts that are addressed in detail by the requirements contained in the other chapters of the Code. The fundamental concepts briefly detailed in this section apply both to prescriptive-based and performance-based life safety designs. Achieving the life safety fundamentals that follow helps to ensure a reasonable level of life safety in building design and arrangement.

1. Provide for adequate safety without dependence on any single safeguard.
2. Provide an appropriate degree of life safety considering the size, shape, and nature of the occupancy.
3. Provide for backup or redundant egress arrangements.
4. Ensure that the egress paths are clear, unobstructed, and unlocked.
5. Ensure that the exits and egress routes are clearly marked to avoid confusion and provide the cues needed for their effective use.
6. Provide adequate lighting.
7. Ensure prompt occupant response by providing early warning of fire.
8. Ensure that required systems facilitate and enhance situation awareness.
9. Ensure the suitable enclosure of vertical openings.

10. Ensure compliance with applicable installation standards.
11. Maintain all required features in proper working order.

**4.5.1 Multiple Safeguards.** The design of every building or structure intended for human occupancy shall be such that reliance for safety to life does not depend solely on any single safeguard. An additional safeguard(s) shall be provided for life safety in case any single safeguard is ineffective due to inappropriate human actions or system failure.

**4.5.2 Appropriateness of Safeguards.** Every building or structure shall be provided with means of egress and other fire and life safety safeguards of the kinds, numbers, locations, and capacities appropriate to the individual building or structure, with due regard to the following:

- (1) Character of the occupancy, including fire load
- (2) Capabilities of the occupants
- (3) Number of persons exposed
- (4) Fire protection available
- (5) Capabilities of response personnel
- (6) Height and construction type of the building or structure
- (7) Other factors necessary to provide occupants with a reasonable degree of safety

### 4.5.3 Means of Egress.

**4.5.3.1 Number of Means of Egress.** Two means of egress, as a minimum, shall be provided in every building or structure, section, and area where size, occupancy, and arrangement endanger occupants attempting to use a single means of egress that is blocked by fire or smoke. The two means of egress shall be arranged to minimize the possibility that both might be rendered impassable by the same emergency condition.

**4.5.3.2 Unobstructed Egress.** In every occupied building or structure, means of egress from all parts of the building shall be maintained free and unobstructed. Means of egress shall be accessible to the extent necessary to ensure reasonable safety for occupants having impaired mobility.

**4.5.3.3 Awareness of Egress System.** Every exit shall be clearly visible, or the route to reach every exit shall be conspicuously indicated. Each means of egress, in its entirety, shall be arranged or marked so that the way to a place of safety is indicated in a clear manner.

**4.5.3.4 Lighting.** Where artificial illumination is needed in a building or structure, egress facilities shall be included in the lighting design.

**4.5.4\* Occupant Notification.** In every building or structure of such size, arrangement, or occupancy that a fire itself might not provide adequate occupant warning, fire alarm systems shall be provided where necessary to warn occupants of the existence of fire.

**A.4.5.4** Fire alarms alert occupants to initiate emergency procedures, facilitate orderly conduct of fire drills, and might initiate response by emergency services.

**4.5.5\* Situation Awareness.** Systems used to achieve the goals of [Section 4.1](#) shall be effective in facilitating and enhancing situation awareness, as appropriate, by building management, other occupants and emergency responders of the functionality or state of critical building systems, the conditions that might warrant emergency response, and the appropriate nature and timing of such responses.

**A.4.5.5** Systems encompass facilities or equipment and people. Included are fire/smoke detection, alarm, and communication systems plus the system status panels in emergency command centers; supervisory systems for various especially critical components (e.g., certain valves) of fire protection systems; certain signs; and the availability of trained staff, notably in health care occupancies.

The provision of [4.5.5](#) recognizes that many of the systems required by the *Code* enhance situation awareness. Examples of such systems are provided in [A.4.5.5](#). The term *situation awareness* is defined in [3.3.249](#). See also [A.3.3.249](#).

**4.5.6 Vertical Openings.** Every vertical opening between the floors of a building shall be suitably enclosed or protected, as necessary, to afford reasonable safety to occupants while using the means of egress and to prevent the spread of fire, smoke, or fumes through vertical openings from floor to floor before occupants have entered exits.

**4.5.7 System Design/Installation.** Any fire protection system, building service equipment, feature of protection, or safeguard provided to achieve the goals of this *Code* shall be designed, installed, and approved in accordance with applicable NFPA standards.

**4.5.8 Maintenance.** Whenever or wherever any device, equipment, system, condition, arrangement, level of protection, or any other feature is required for compliance with the provisions of this *Code*, such device, equipment, system, condition, arrangement, level of protection, or other feature shall thereafter be maintained, unless the *Code* exempts such maintenance.

---

## 4.6 General Requirements

### 4.6.1 Authority Having Jurisdiction.

The authority having jurisdiction is the person or office enforcing the *Code*. In cases where the *Code* is legally enforced, the AHJ is usually a fire marshal or building official. The AHJ can also be a safety office, an insurance engineering department, an accreditation service, other agency, or specified personnel within these

groups, especially where the *Code* is enforced at other than a governmental level.

The term *authority having jurisdiction* is used extensively within all NFPA codes and standards. As such, its definition (see [3.2.2](#) and [A.3.2.2](#)) is an NFPA official definition that must be adopted without change for each code and standard. The NFPA official definitions appear in [Section 3.2](#), and the *Code*-specific definitions appear in [Section 3.3](#).

It is common for multiple authorities having jurisdiction to review the same project while enforcing this *Code*, other codes, or both. For example, under the *Code*, several agencies — such as state and local fire marshals; federal, state, and local health care licensing agencies; The Joint Commission (formerly the Joint Commission on Accreditation of Healthcare Organizations, or JCAHO) accreditation personnel; insurance inspectors; and building inspectors — perform inspections in health care facilities.

**4.6.1.1** The authority having jurisdiction shall determine whether the provisions of this *Code* are met.

**4.6.1.2** Any requirements that are essential for the safety of building occupants and that are not specifically provided for by this *Code* shall be determined by the authority having jurisdiction.

The provisions of [Section 4.6](#) give the authority having jurisdiction responsibility for the final determination of whether adequate life safety is provided in a building. When the authority having jurisdiction determines that the *Code* has not specifically addressed a particular life safety situation, the authority can supplement the requirements in the *Code* to address the situation. The power to supplement requirements is an important responsibility, because the *Code* cannot anticipate every type of building and occupancy configuration.

**4.6.1.3** Where it is evident that a reasonable degree of safety is provided, any requirement shall be permitted to be modified if, in the judgment of the authority having jurisdiction, its application would be hazardous under normal occupancy conditions.

The provision of [4.6.1.3](#) gives the authority having jurisdiction latitude in permitting a requirement to be modified if the strict enforcement of the provision would otherwise create more of a hazard and, thus, less overall life safety than would be achieved by modification. For example, the *Code* requires an exit sign at an exit and, via the provisions of [7.10.1.2](#), requires that the sign be readily visible from any direction of exit access. If the exit door in question were installed in the plane of a corridor wall, the exit sign would need to be positioned perpendicular to the corridor wall. If there is limited headroom at the door, perhaps due to a ceiling projection such as a beam running across the corridor at that point, the exit sign might create the potential for occupants to bump their heads. This provision permits the authority having jurisdiction to allow the exit sign to be mounted flush against

the corridor wall, based on the judgment that a reasonable degree of safety is provided.

#### 4.6.1.4 Technical Assistance.

**4.6.1.4.1** The authority having jurisdiction shall be permitted to require a review by an approved independent third party with expertise in the matter to be reviewed at the submitter's expense. [1:1.15.1]

**4.6.1.4.2** The independent reviewer shall provide an evaluation and recommend necessary changes of the proposed design, operation, process, or new technology to the authority having jurisdiction. [1:1.15.2]

**4.6.1.4.3** The authority having jurisdiction shall be authorized to require design submittals to bear the stamp of a registered design professional. [1:1.15.3]

The provisions of 4.6.1.4 are extracted from NFPA 1, *Fire Code*.<sup>1</sup> The provisions recognize that the authority having jurisdiction might not have the resources needed to fully evaluate a particular design, system, or installation as required by 4.6.1.1. Professional services can be utilized to supplement the AHJ's work.

**4.6.2 Previously Approved Features.** Where another provision of this *Code* exempts a previously approved feature from a requirement, the exemption shall be permitted, even where the following conditions exist:

- (1) The area is being modernized, renovated, or otherwise altered.
- (2) A change of occupancy has occurred, provided that the feature's continued use is approved by the authority having jurisdiction.

The term *previously approved* is defined in 3.3.214 as "that which was acceptable to the authority having jurisdiction prior to the date this edition of the *Code* went into effect." In a relatively few cases, the responsible technical committees have earmarked specific features that can be continued in use if such features were previously approved. For example, in 40.2.2.8, regarding existing, previously approved escalators in industrial occupancies, the message to the current AHJ is that if an AHJ of an earlier period judged the escalator as adequate for use within the means of egress, the escalator should continue to be approved for use. The AHJ that gave the original approval had detailed criteria in the *Code* at that time. The criteria no longer exist, because new escalators are not permitted to comprise any of the required means of egress. The current AHJ is expected to continue recognizing the earlier approval. However, if there is a change of occupancy, the previously approved feature must also receive the current approval of the AHJ, because the feature that had been acceptable in the original occupancy might not be acceptable for the new occupancy. See 4.6.2(2).

Contrast the preceding example with the treatment of existing stairs in 7.2.2.1.2(2), where approved, existing noncomplying stairs are recognized in lieu of stairs complying with the detailed criteria of 7.2.2. The term *approved existing*, which is different from the term *previously approved*, is defined in 3.3.81.1 as "that which is already in existence on the date this edition of the *Code* goes into effect and is acceptable to the authority having jurisdiction." In this case, it does not matter how an earlier AHJ ruled on the acceptability of the stair. The current AHJ must evaluate the noncomplying stair and determine whether it is acceptable for continued use.

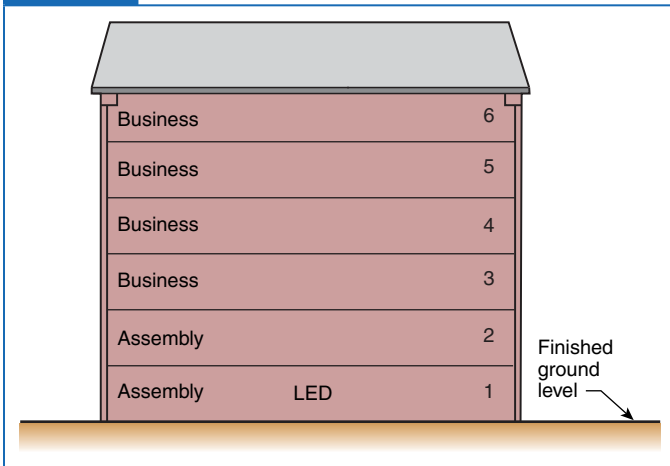

**4.6.3 Stories in Height.** Unless otherwise specified in another provision of this *Code*, the stories in height of a building shall be determined as follows:

- (1) The stories in height shall be counted starting with the level of exit discharge and ending with the highest occupiable story containing the occupancy considered.
- (2) Stories below the level of exit discharge shall not be counted as stories.
- (3) Interstitial spaces used solely for building or process systems directly related to the level above or below shall not be considered a separate story.
- (4) A mezzanine shall not be counted as a story for the purpose of determining the allowable stories in height.
- (5) For purposes of application of the requirements for occupancies other than assembly, health care, detention and correctional, and ambulatory health care, where a maximum one-story abovegrade parking structure, enclosed, open, or a combination thereof, of Type I or Type II (222) construction or open Type IV construction, with grade entrance, is provided under a building, the number of stories shall be permitted to be measured from the floor above such a parking area.

The provisions of 4.6.3 support consistent use of the term *stories in height* in other sections of the *Code*. Criteria typically presented in the \_\_.1.6 subsection of an occupancy chapter, related to minimum construction requirements, use stories in height as thresholds for requiring specific building construction types. Similarly, other *Code* provisions utilize stories in height as a threshold at which a requirement applies. For example, see 38.3.4.1 and 39.3.4.1, where a fire alarm system is required for business occupancies where the building is three or more stories in height. The examples that follow demonstrate application of the provisions of 4.6.3.

#### Example 1

Exhibit 4.2 depicts a six-story existing building. Floors 1 and 2 are occupied as an assembly occupancy. Floors 3 through 6 are occupied as a business occupancy. The first story, which is used as an assembly occupancy, is the level of exit discharge, as it is

**Exhibit 4.2**

An assembly occupancy two stories in height and a business occupancy six stories in height.

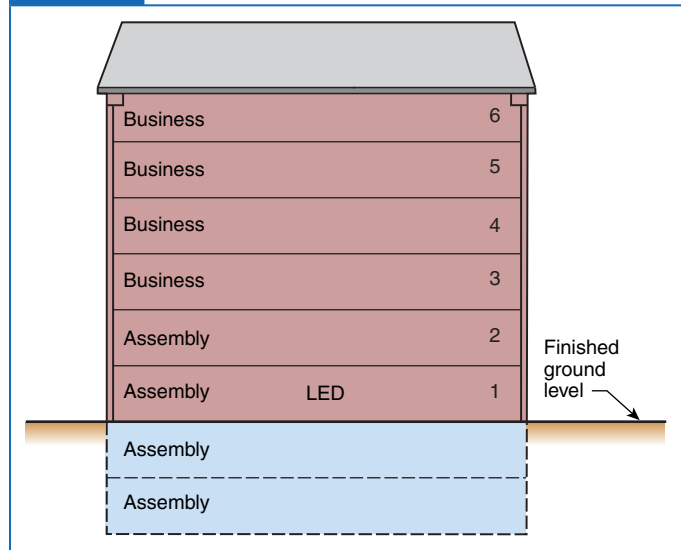

the lowest story from which not less than 50 percent of the required number of means of egress and not less than 50 percent of the required egress capacity from that story discharge directly outside at the finished ground level (see definition of *level of exit discharge* in 3.3.85.1). The provision of 4.6.3(1) directs that the stories in height are to be counted starting at the level of exit discharge and ending at the highest occupiable story containing the occupancy considered. The second story is the highest occupiable story containing the assembly occupancy. The sixth story is the highest occupiable story containing the business occupancy. This leads to classifying the building as being two stories in height for the assembly occupancy and six stories in height for the business occupancy.

### Example 2

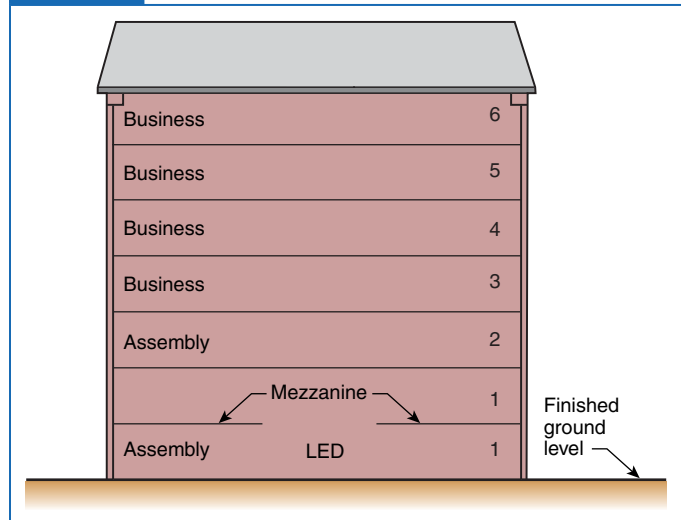

Exhibit 4.3 depicts the building addressed in Example 1 but has two additional floor levels, both located below the level of exit discharge. The provision of 4.6.3(2) directs that stories below the level of exit discharge are not to be counted as stories for purposes of determining stories in height. This leads to classifying the building as being two stories in height for the assembly occupancy and six stories in height for the business occupancy, as was done in Example 1 where no basement levels were present.

### Example 3

Exhibit 4.4 depicts a building similar to that addressed in Example 1, but the first story assembly occupancy has a higher ceiling height and a mezzanine along the exterior walls. The provision of 4.6.3(4) directs that a mezzanine is not to be counted as a story for purposes of determining stories in height. This leads to classifying the building as being two stories in height for the assembly occupancy and six stories in height for the business occupancy.

**Exhibit 4.3**

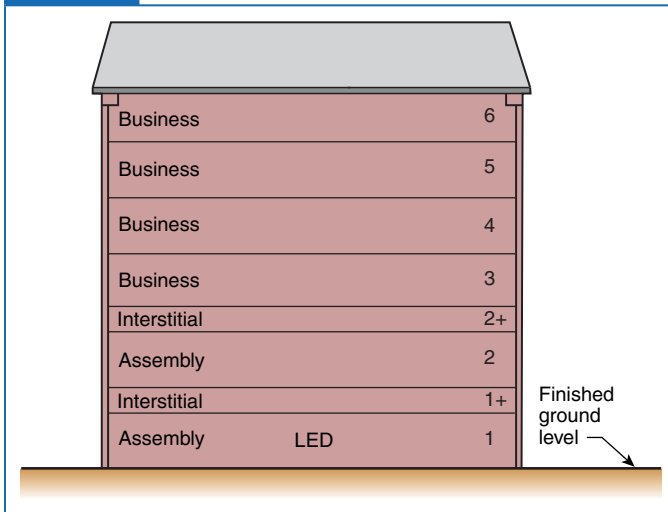

Another assembly occupancy two stories in height and a business occupancy six stories in height.

**Exhibit 4.4**

An assembly occupancy two stories in height and a business occupancy six stories in height.

### Example 4

Exhibit 4.5 depicts a building similar to that addressed in Example 1, but the first two stories, which are used as an assembly occupancy, have an interstitial space above their ceilings used to house mechanical equipment serving those two floors. The provision of 4.6.3(3) directs that interstitial spaces used solely for building or process systems directly related to the level above or below are not to be counted as separate stories for purposes of determining stories in height. This leads to classifying the building as being two stories in height for the assembly occupancy and six stories in height for the business occupancy.

**Exhibit 4.5**

An assembly occupancy two stories in height and a business occupancy six stories in height.

**Example 5**

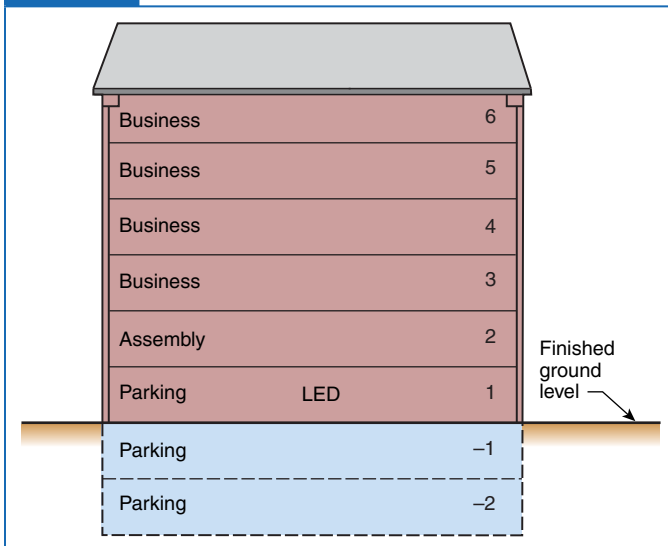

**Exhibit 4.6** depicts a building similar to that addressed in Example 1, but the first story is used as a parking structure, as are the two levels below the level of exit discharge. The entire building is of Type II(222) construction (see [Table A.8.2.1.2](#)). The provision of [4.6.3\(5\)](#) directs that where a maximum one-story abovegrade parking structure, whether enclosed, open, or a combination thereof, of Type I or Type II(222) construction or of open Type IV construction, with grade entrance, is provided under a building of occupancies other than assembly, health care, detention and

correctional, or ambulatory health care, the number of stories used in determining stories in height is permitted to be measured from the floor above such parking area. The presence of the assembly occupancy precludes the level of exit discharge used as parking from being excluded from the count of stories in height for the assembly occupancy, but does not preclude such for the business occupancy. This leads to classifying the building as being two stories in height for the assembly occupancy and five stories in height for the business occupancy.

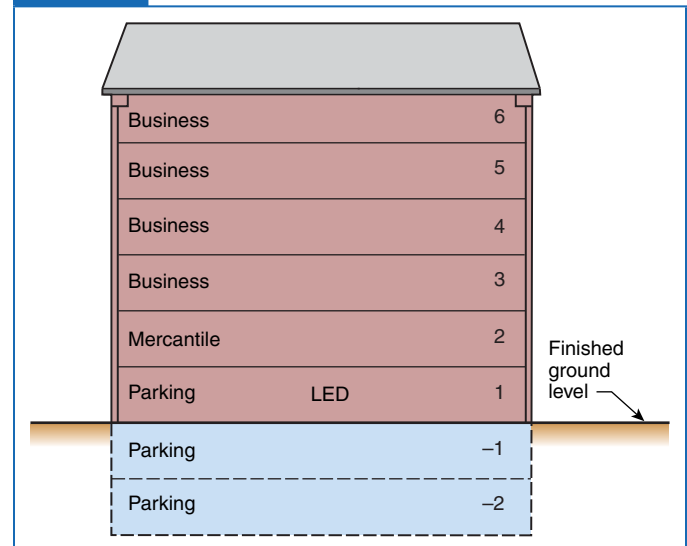

**Example 6**

**Exhibit 4.7** depicts a building similar to that addressed in Example 5, but the second story is used as a mercantile occupancy. The entire building is of Type II(222) construction (see [Table A.8.2.1.2](#)). The provision of [4.6.3\(5\)](#) directs that where a maximum one-story abovegrade parking structure, whether enclosed, open, or a combination thereof, of Type I or Type II(222) construction or of open Type IV construction, with grade entrance, is provided under a building of occupancies other than assembly, health care, detention and correctional, or ambulatory health care, the number of stories used in determining stories in height is permitted to be measured from the floor above such parking area. Given that the occupancies involved (i.e., mercantile and business) are not assembly, health care, detention and correctional, or ambulatory health care, the floor used for parking at the level of exit discharge can be discounted in determining the stories in height. This leads to classifying the building as being one story in height for the mercantile occupancy and five stories in height for the business occupancy.

Note that the text of [4.6.3\(5\)](#) was revised for the 2012 edition of the *Code* to correct an unintentional limitation on the use

**Exhibit 4.6**

An assembly occupancy two stories in height and a business occupancy five stories in height.

**Exhibit 4.7**

A mercantile occupancy one story in height and a business occupancy five stories in height.

of the provision for other than assembly, health care, detention and correctional, and ambulatory health care occupancies. In the 2009 edition, the exclusion related to assembly, health care, detention and correctional, and ambulatory health care occupancies was positioned in the middle of the sentence, with the inadvertent effect of preventing the business occupancies depicted in [Exhibit 4.6](#) from excluding the parking story from the stories-in-height count due to the presence of the assembly occupancy in the same building. In other words, a strict reading of the former text would have resulted in [Exhibit 4.6](#) depicting a business occupancy six (not five) stories in height.

#### 4.6.4 Historic Buildings.

**4.6.4.1** Rehabilitation projects in historic buildings shall comply with [Chapter 43](#).

**4.6.4.2\*** The provisions of this *Code* shall be permitted to be modified by the authority having jurisdiction for buildings or structures identified and classified as historic buildings or structures where it is evident that a reasonable degree of safety is provided.

**A.4.6.4.2** See [A.4.6.5](#).

Rather than providing historic buildings with a blanket exemption from *Code* requirements, the provision of [4.6.4.2](#) reinforces the concept that existing buildings, as well as new construction, need to meet minimum life safety criteria. This provision permits the authority having jurisdiction to offer some leniency — as long as the AHJ judges that a reasonable degree of safety is provided, compliance with modified requirements is adequate.

Historic buildings might have numerous design defects, such as open stair shafts or highly combustible interior finishes. Rather than waiving requirements, the authority having jurisdiction might require that the facility attain a level of safety equivalent to, or nearly equivalent to, that mandated by the *Code*. For example, the AHJ might require the use of sprinkler systems, smoke detection systems, voice alarm systems for staged evacuation, smoke control systems, or other appropriate features to overcome the existing life safety defects. The use of such alternatives could raise the building's life safety to levels many times greater than those that previously existed without requiring the rebuilding of the structure to the *Code's* specification-based requirements, which might destroy the historical character of the structure.

The provision of [4.6.4.2](#), which gives the AHJ permission to modify *Code* requirements, applies only to a historic building for which there is no ongoing rehabilitation. Where historic buildings are rehabilitated, the provisions of [Chapter 43](#) must be met as required by [4.6.4.1](#). See [Chapter 43](#), Building Rehabilitation, especially [Section 43.10](#).

**4.6.5\* Modification of Requirements for Existing Buildings.** Where it is evident that a reasonable degree of safety is provided, the requirements for existing buildings shall

be permitted to be modified if their application would be impractical in the judgment of the authority having jurisdiction.

**A.4.6.5** In existing buildings, it is not always practical to strictly apply the provisions of this *Code*. Physical limitations can cause the need for disproportionate effort or expense with little increase in life safety. In such cases, the authority having jurisdiction needs to be satisfied that reasonable life safety is ensured.

In existing buildings, it is intended that any condition that represents a serious threat to life be mitigated by the application of appropriate safeguards. It is not intended to require modifications for conditions that do not represent a significant threat to life, even though such conditions are not literally in compliance with the *Code*.

An example of what is intended by [4.6.5](#) would be a historic ornamental guardrail baluster with spacing that does not comply with the 4 in. (100 mm) requirement. Because reducing the spacing would have minimal impact on life safety but could damage the historic character of the guardrail, the existing spacing might be approved by the authority having jurisdiction.

The provisions of [4.6.5](#) give the authority having jurisdiction some leeway in applying the *Code* to existing buildings. The *Code* recognizes that there might be situations where applying the requirements to existing situations is not practical, so the provisions of [4.6.5](#) give the authority having jurisdiction the authority to modify these requirements. However, the *Code* re-emphasizes that a reasonable degree of safety must be provided.

**4.6.6 Time Allowed for Compliance.** A limited but reasonable time, commensurate with the magnitude of expenditure, disruption of services, and degree of hazard, shall be allowed for compliance with any part of this *Code* for existing buildings.

In some cases, appreciable costs — in terms of actual monetary expenditures and disruption of daily activities — might be involved in immediately bringing an existing building into *Code* compliance. Where this is true, it is appropriate for the operator or owner of the facility to formulate a schedule, approved by the authority having jurisdiction, that allows suitable periods of time for correcting various deficiencies. However, the degree of hazard is an important consideration in this instance; if the degree of hazard is serious enough, it might be necessary to close the building to occupancy while renovations are made to bring the building features associated with the serious hazard into compliance. Once the building is reoccupied, the AHJ might permit some reasonable, additional time for bringing the remaining deficient features into *Code* compliance with the requirements that apply specifically to existing buildings.

#### 4.6.7 Building Rehabilitation.

Editions of the *Code* prior to 2006 required modernizations, renovations, additions, and changes of occupancy to comply with the requirements for new construction. [Chapter 43](#), Building

Rehabilitation, was added in 2006. It was written to encourage the adaptive reuse of existing structures. The former requirement that rehabilitation projects must comply with the requirements for new construction is relaxed. **Chapter 43** imposes those requirements necessary to achieve the intended level of life safety in lieu of requiring strict compliance with the requirements applicable to new buildings.

The provisions of **Chapter 43** are permitted to be used only if the existing building is brought into compliance with the appropriate occupancy chapter requirements applicable to existing occupancies. See **43.1.2.1(1)**. For example, if an existing business occupancy is to undergo renovation, the provisions of **Chapter 43** are permitted to be used only if the existing building is brought into compliance with the requirements of **Chapter 39**, Existing Business Occupancies. Thus, the existing business occupancy building undergoing the renovation is held, as a starting point, to the same requirements that apply to any other existing business occupancy building. Then, per **43.1.2.1(2)**, requirements related to the renovation work being undertaken are added.

Some of the occupancy chapters have requirements that supplement those of **Chapter 43** and impose the requirements for new construction on existing buildings that are being rehabilitated, including those situations in which the use is changed to increase the occupant load. For example, mercantile occupancies are further subclassified as a Class A, Class B, or Class C mercantile occupancy, based on the floor area used for sales purposes. For the purposes of this example, consider that the rehabilitation project involves an addition to an existing mercantile occupancy. If consideration of the combined space created by the addition and the existing portion of the building results in a change of mercantile occupancy subclassification (e.g., a reclassification from Class C to Class B or from Class B to Class A), the existing portion of the building must also meet the requirements applicable to new construction. See **36.1.1.5.3** and **37.1.1.5.3**.

For assembly occupancies, the same concept applies, but its application criteria are specified differently, given that assembly occupancies no longer use the subclassification scheme of editions earlier than 1997 (i.e., Class A, Class B, and Class C). The existing portion of the assembly occupancy building is required to meet the provisions that apply to new construction under either of the following conditions (see **13.1.1.6**):

1. The occupant load of the combined space created by the addition and the existing assembly area increases from less than 500 to more than 500, so as to require a third exit.
2. The occupant load of the combined space created by the addition and the existing assembly area increases from less than 1000 to more than 1000, so as to require a fourth exit.

**4.6.7.1** Rehabilitation work on existing buildings shall be classified as one of the following work categories in accordance with **43.2.2.1**:

- (1) Repair
- (2) Renovation

- (3) Modification
- (4) Reconstruction
- (5) Change of use or occupancy classification
- (6) Addition

**4.6.7.2** Rehabilitation work on existing buildings shall comply with **Chapter 43**.

**4.6.7.3** Except where another provision of this *Code* exempts a previously approved feature from a requirement, the resulting feature shall be not less than that required for existing buildings.

**4.6.7.4\*** Existing life safety features that exceed the requirements for new buildings shall be permitted to be decreased to those required for new buildings.

**A.4.6.7.4** In some cases, the requirements for new construction are less restrictive, and it might be justifiable to permit an existing building to use the less restrictive requirements. However, extreme care needs to be exercised when granting such permission, because the less restrictive provision might be the result of a new requirement elsewhere in the *Code*. For example, in editions of the *Code* prior to 1991, corridors in new health care occupancies were required to have a 1-hour fire resistance rating. Since 1991, such corridors have been required only to resist the passage of smoke. However, this provision is based on the new requirement that all new health care facilities be protected throughout by automatic sprinklers. (See **A.4.6.7.5**.)

**4.6.7.5\*** Existing life safety features that do not meet the requirements for new buildings, but that exceed the requirements for existing buildings, shall not be further diminished.

**A.4.6.7.5** An example of what is intended by **4.6.7.4** and **4.6.7.5** follows. In a hospital that has 6 ft (1830 mm) wide corridors, such corridors cannot be reduced in width, even though the provisions for existing hospitals do not require 6 ft (1830 mm) wide corridors. However, if a hospital has 10 ft (3050 mm) wide corridors, they are permitted to be reduced to 8 ft (2440 mm) in width, which is the requirement for new construction. If the hospital corridor is 36 in. (915 mm) wide, it would have to be increased to 48 in. (1220 mm), which is the requirement for existing hospitals.

The intent behind **4.6.7.4** and **4.6.7.5** is to prevent existing life safety features that exceed the requirement for existing buildings from being decreased to a level less than that required for new construction. For example, a new hospital is constructed with 8 ft (2440 mm) wide corridors for compliance with **18.2.3.4**. In subsequent years the building becomes an existing hospital subject to the provisions of **Chapter 19**, Existing Health Care Occupancies. The minimum corridor width required by **19.2.3.4** for an existing hospital is 48 in. (1220 mm). The minimum 48 in. (1220 mm) criterion is meant to apply to existing situations, but is not intended to permit the existing 8 ft (2440 mm) corridor to

be decreased in width. This example is addressed in additional detail in [A.4.6.7.5](#).

For a similar concept related to the removal of existing life safety features, see [4.6.12.2](#).

**4.6.8 Provisions in Excess of Code Requirements.** Nothing in this *Code* shall be construed to prohibit a better building construction type, an additional means of egress, or an otherwise safer condition than that specified by the minimum requirements of this *Code*.

Although the *Life Safety Code* is a minimum requirement code, it does not prohibit the use of a design that exceeds the provisions of the *Code*. Although, in practice, economic considerations usually discourage the use of a design that exceeds minimum requirements, there have been instances where money was saved or additional money was generated when *Code* provisions were exceeded. For example, a hotel was constructed with full automatic sprinkler protection, although such protection was not required by the *Code* in effect at the time. Sprinklering the building permitted a third stairway to be eliminated because of the increased travel distance permitted in a sprinklered building. The construction cost of the stair was saved, and additional revenue-producing guest rooms were built in the space that the stair otherwise would have occupied.

#### 4.6.9 Conditions for Occupancy.

**4.6.9.1** No new construction or existing building shall be occupied in whole or in part in violation of the provisions of this *Code*, unless the following conditions exist:

- (1) A plan of correction has been approved.
- (2) The occupancy classification remains the same.
- (3) No serious life safety hazard exists as judged by the authority having jurisdiction.

From an enforcement standpoint, [4.6.9.1](#) is probably one of the most important requirements in the *Code*, because it states that a building, whether new or existing, cannot be occupied if it is in violation of the provisions of the *Code*.

Because the *Code* applies retroactively, [4.6.9.1](#) prohibits the use of existing, nonconforming facilities. However, [4.6.9.1](#) does permit the building to continue to be used, provided that the occupancy classification remains the same and there is no serious life safety hazard, as judged by the authority having jurisdiction, that would constitute an imminent threat. Such permission does not exempt the building from compliance with the *Code*. A limited, but reasonable, time (see [4.6.6](#)) for bringing the building into compliance with the *Code* to the extent deemed necessary by the AHJ under [4.6.5](#) must be established and fulfilled.

Another way for an existing building to be deemed *Code* compliant is for the AHJ to modify a requirement in accordance with [4.6.5](#) after determining that (1) a reasonable degree of safety is provided in the absence of strict compliance with the specification-based requirement, and (2) application of the specification-based requirement would be impractical.

**4.6.9.2** Where compliance with this *Code* is effected by means of a performance-based design, the owner shall annually certify compliance with the conditions and limitations of the design by submitting a warrant of fitness acceptable to the authority having jurisdiction. The warrant of fitness shall attest that the building features, systems, and use have been inspected and confirmed to remain consistent with design specifications outlined in the documentation required by [Section 5.8](#) and that such features, systems, and use continue to satisfy the goals and objectives specified in [Sections 4.1](#) and [4.2](#). (See [Chapter 5](#).)

Traditional, specification-based life safety systems rely on the combined effect of all required features, systems, and arrangements to provide the intended level of life safety. This overlap of protection schemes and the resulting redundancy in protection methods, which are mandated by the prescriptive requirements, have historically provided flexibility for a building to undergo changes in how its space is configured and used. For example, a business occupancy floor arranged to provide executives with private offices could be renovated by removing the office walls, installing modular furniture and cubicles, and creating an open-office floor plan for use by telemarketers. The occupancy would remain a business occupancy, and compliance with the provisions of [Section 43.5](#) applicable to modification (i.e., reconfiguration of space) would have a minor effect on changing the level of life safety that existed prior to the renovation.

However, had the original executive office floor been designed using the performance-based option, the removal of office walls would need to be analyzed with respect to its effect on the life safety systems. The performance-based design might have been based on a scenario in which a fire would not propagate beyond one of the private offices due to fire-rated compartmentation. Removing the office walls and creating an open floor plan would result in the loss of the performance-based design's compartmentation premise. Further analysis would be needed to determine whether the original life safety systems continued to meet the goals and objectives after the renovation.

Although the example cited in this commentary centers on a modification that involves removal of office walls, subtle changes that “creep” into a building over time might also adversely affect a life safety system designed using the performance-based option. For this reason, [4.6.9.2](#) requires annual certification via a warrant of fitness.

The provisions of [4.6.9.2](#) are located in [Chapter 4](#) in the hope that the requirement will be noticed and enforced. If the requirement were to appear in [Chapter 5](#), Performance-Based Option, it might go unnoticed after the performance-based design is completed and the certificate of occupancy issued.

#### 4.6.10 Construction, Repair, and Improvement Operations.

**4.6.10.1\*** Buildings, or portions of buildings, shall be permitted to be occupied during construction, repair, alterations, or additions only where required means of egress and required fire

protection features are in place and continuously maintained for the portion occupied or where alternative life safety measures acceptable to the authority having jurisdiction are in place.

**A.4.6.10.1** Fatal fires have occurred when, for example, a required stair has been closed for repairs or removed for rebuilding, or when a required automatic sprinkler system has been shut off to change piping.

The provisions of [4.6.10.1](#) help to control a relatively common practice — the occupation of completed portions of a partially completed structure. The *Code* permits such occupation if certain conditions are met. For example, the *Code* requires that egress features for the portion occupied be complete and maintained to be usable. In many cases, the egress facilities, although completed, are not usable because they are blocked with stored building materials and equipment needed for the ongoing construction, or doors are locked to limit access to parts of the building still under construction. In such cases, occupancy is prohibited.

The *Code* also requires that fire protection features be in place and be continuously maintained. The incidence of fire is more frequent, and therefore more likely, during construction or rehabilitation. Extra caution and concern need to be exercised to ensure adequate egress capacity and arrangement during periods of construction in any occupied building.

[Paragraph 4.6.10.1](#) recognizes that, in lieu of strict adherence to the egress and fire protection features, alternative life safety measures might make the building safe enough to be occupied. As usual, the authority having jurisdiction is charged with judging whether the alternative measures provide an acceptable remedy. [Paragraph 4.6.10.1](#) is conceptually similar to [4.6.9.1](#).

**4.6.10.2\*** In buildings under construction, adequate escape facilities shall be maintained at all times for the use of construction workers. Escape facilities shall consist of doors, walkways, stairs, ramps, fire escapes, ladders, or other approved means or devices arranged in accordance with the general principles of the *Code* insofar as they can reasonably be applied to buildings under construction.

**A.4.6.10.2** See also NFPA 241, *Standard for Safeguarding Construction, Alteration, and Demolition Operations*.

**4.6.10.3** Flammable or explosive substances or equipment for repairs or alterations shall be permitted in a building while the building is occupied if the condition of use and safeguards provided do not create any additional danger or impediment to egress beyond the normally permissible conditions in the building.

**4.6.11 Change of Use or Occupancy Classification.** In any building or structure, whether or not a physical alteration is needed, a change from one use or occupancy classification to another shall comply with [4.6.7](#).

Change of use or change of occupancy classification is treated as a category of rehabilitation. Such changes are required by

[4.6.7](#) to comply with the provisions of [Chapter 43, Building Rehabilitation](#).

#### 4.6.12 Maintenance, Inspection, and Testing.

**4.6.12.1** Whenever or wherever any device, equipment, system, condition, arrangement, level of protection, fire-resistive construction, or any other feature is required for compliance with the provisions of this *Code*, such device, equipment, system, condition, arrangement, level of protection, fire-resistive construction, or other feature shall thereafter be continuously maintained. Maintenance shall be provided in accordance with applicable NFPA requirements or requirements developed as part of a performance-based design, or as directed by the authority having jurisdiction.

[Paragraph 4.6.12.1](#) emphasizes the importance of maintaining items required by the *Code*. It is useless to have an egress door that will not open, a self-closing device that does not close the door, or a sprinkler system with no water.

**4.6.12.2** No existing life safety feature shall be removed or reduced where such feature is a requirement for new construction.

[Paragraph 4.6.12.2](#) works in concert with [4.6.7.4](#) and [4.6.7.5](#) to prevent the downgrading or removal of features and systems originally installed to meet the requirements applicable to new construction. The following examples illustrate the use of [4.6.12.2](#).

##### Example 1

The operator of an existing, nonsprinklered office building with multiple tenants per floor asks a fire protection consultant whether the *Code* will permit the removal of the existing 1-hour fire resistance-rated corridors. The consultant evaluates the request by classifying the building as an existing business occupancy subject to the requirements of [Chapter 39](#). The consultant notes that [39.3.6](#) imposes no corridor requirement for existing business occupancies. The consultant notes that [38.3.6.1](#) requires a 1-hour fire resistance-rated corridor for new business occupancies unless the building is sprinklered, is occupied by a single tenant, or is of the open floor plan layout. A new, nonsprinklered business occupancy building with the same features as the existing, nonsprinklered building would therefore require a 1-hour fire resistance-rated corridor. The consultant judges that [4.6.12.2](#) prohibits the removal of the existing 1-hour fire resistance-rated corridor.

##### Example 2

The operator of an existing, sprinklered office building with multiple tenants per floor asks a fire protection consultant whether the *Code* will permit the removal of the existing 1-hour fire resistance-rated corridors. The consultant evaluates the request by classifying the building as an existing business

occupancy subject to the requirements of [Chapter 39](#). The consultant notes that [39.3.6](#) imposes no corridor requirement for existing business occupancies. The consultant notes that [38.3.6.1](#) requires a 1-hour fire resistance-rated corridor for new business occupancies unless the building is sprinklered, is occupied by a single tenant, or is of the open floor plan layout. A new, sprinklered business occupancy building with the same features as the existing, sprinklered building would therefore be exempt from the 1-hour fire resistance-rated corridor requirement. The consultant judges that the existing 1-hour fire resistance-rated corridors can be removed without violating the provision of [4.6.12.2](#).

**4.6.12.3\*** Existing life safety features obvious to the public, if not required by the *Code*, shall be either maintained or removed.

**A.4.6.12.3** Examples of such features include automatic sprinklers, fire alarm systems, standpipes, and portable fire extinguishers. The presence of a life safety feature, such as sprinklers or fire alarm devices, creates a reasonable expectation by the public that these safety features are functional. When systems are inoperable or taken out of service but the devices remain, they present a false sense of safety. Also, before taking any life safety features out of service, extreme care needs to be exercised to ensure that the feature is not required, was not originally provided as an alternative or equivalent, or is no longer required due to other new requirements in the current *Code*. It is not intended that the entire system or protection feature be removed. Instead, components such as sprinklers, initiating devices, notification appliances, standpipe hose, and exit systems should be removed to reduce the likelihood of relying on inoperable systems or features. Conversely, equipment, such as fire or smoke dampers, that is not obvious to the public should be able to be taken out of service if no longer required by this *Code*. Where a door that is not required to be fire protection-rated is equipped with a fire protection listing label, it is not the intent of [4.6.12.3](#) to require such door to be self- or automatic-closing due merely to the presence of the label.

The *Code* directs that nonrequired life safety features that are obvious to the public be either maintained or removed to prevent false expectations or a false sense of security by building occupants. For example, if the water supply to a nonrequired wet standpipe system were permanently shut off because the system piping leaked, but the hose and nozzle for occupant use were left attached to the standpipe, an occupant could be endangered while attempting to use the system. If the nonrequired standpipe system were turned off and abandoned, it would be necessary, as a minimum, to remove all hose and nozzles and to place prominent signage at each outlet station advising that the system is out of service. The standpipe system piping, however, should not have to be removed.

**4.6.12.4** Any device, equipment, system, condition, arrangement, level of protection, fire-resistive construction, or any other feature requiring periodic testing, inspection, or operation to

ensure its maintenance shall be tested, inspected, or operated as specified elsewhere in this *Code* or as directed by the authority having jurisdiction.

**4.6.12.5** Maintenance, inspection, and testing shall be performed under the supervision of a responsible person who shall ensure that testing, inspection, and maintenance are made at specified intervals in accordance with applicable NFPA standards or as directed by the authority having jurisdiction.

**Subsection 4.6.12** stresses that the application of maintenance, inspection, and testing requires a three-component approach. None of the three components — maintenance, inspection, or testing — applied alone, or applied in tandem with only one of the other two, will ensure that the life safety features and systems will continue to work as required.

#### **4.6.13\* Noncombustible Material.**

**A.4.6.13** The provisions of [4.6.13](#) do not require inherently noncombustible materials to be tested in order to be classified as noncombustible materials.

**4.6.13.1** A material that complies with any of the following shall be considered a noncombustible material:

- (1)\* A material that, in the form in which it is used and under the conditions anticipated, will not ignite, burn, support combustion, or release flammable vapors when subjected to fire or heat
- (2) A material that is reported as passing ASTM E 136, *Standard Test Method for Behavior of Materials in a Vertical Tube Furnace at 750 Degrees C*
- (3) A material that is reported as complying with the pass/fail criteria of ASTM E 136 when tested in accordance with the test method and procedure in ASTM E 2652, *Standard Test Method for Behavior of Materials in a Tube Furnace with a Cone-shaped Airflow Stabilizer, at 750 Degrees C*

**A.4.6.13.1(1)** Examples of such materials include steel, concrete, masonry, and glass.

**4.6.13.2** Where the term *limited-combustible* is used in this *Code*, it shall also include the term *noncombustible*.

**Subsection 4.6.13** represents a refinement of the definition of the term *noncombustible (material)* that appeared in [Chapter 3](#) of earlier editions. The former definition included requirements, which should not be part of defined terms in [Chapter 3](#). *Code* users who refer to the definition of *noncombustible (material)* in [Chapter 3](#) are directed by [3.3.171.4](#) to see [4.6.13](#). The provision of [4.6.13.1\(1\)](#) recognizes that some materials are inherently noncombustible and do not require testing to receive a classification of noncombustible. The text of [A.4.6.13.1\(1\)](#) provides examples of such materials.

**4.6.14\* Limited-Combustible Material.** A material shall be considered a limited-combustible material where all the conditions of [4.6.14.1](#) and [4.6.14.2](#), and the conditions of either [4.6.14.3](#) or [4.6.14.4](#), are met.

**A.4.6.14** Materials subject to increase in combustibility or flame spread index beyond the limits herein established through the effects of age, moisture, or other atmospheric condition are considered combustible. (See NFPA 259, *Standard Test Method for Potential Heat of Building Materials*, and NFPA 220, *Standard on Types of Building Construction*.)

**4.6.14.1** The material shall not comply with the requirements for noncombustible material in accordance with **4.6.13**.

**4.6.14.2** The material, in the form in which it is used, shall exhibit a potential heat value not exceeding 3500 Btu/lb (8141 kJ/kg) where tested in accordance with NFPA 259, *Standard Test Method for Potential Heat of Building Materials*.

**4.6.14.3** The material shall have the structural base of a noncombustible material with a surfacing not exceeding a thickness of 1/8 in. (3.2 mm) where the surfacing exhibits a flame spread index not greater than 50 when tested in accordance with ASTM E 84, *Standard Test Method for Surface Burning Characteristics of Building Materials*, or ANSI/UL 723, *Standard for Test for Surface Burning Characteristics of Building Materials*.

**4.6.14.4** The material shall be composed of materials that, in the form and thickness used, neither exhibit a flame spread index greater than 25 nor evidence of continued progressive combustion when tested in accordance with ASTM E 84, *Standard Test Method for Surface Burning Characteristics of Building Materials*, or ANSI/UL 723, *Standard for Test for Surface Burning Characteristics of Building Materials*, and shall be of such composition that all surfaces that would be exposed by cutting through the material on any plane would neither exhibit a flame spread index greater than 25 nor exhibit evidence of continued progressive combustion when tested in accordance with ASTM E 84 or ANSI/UL 723.

**4.6.14.5** Where the term *limited-combustible* is used in this Code, it shall also include the term *noncombustible*.

Subsection **4.6.14** represents a refinement of the definition of the term *limited-combustible (material)* that appeared in **Chapter 3** of earlier editions. The former definition included requirements, which should not be part of defined terms in **Chapter 3**. Code users who refer to the definition of *limited-combustible (material)* in **Chapter 3** are directed by **3.3.171.2** to see **4.6.14**. The provision of **4.6.14.5** explains that, wherever the Code requires a material to be limited-combustible, the use of a noncombustible material is permitted.

**4.6.15 Grade Plane.** The grade plane shall be established by calculating the average of the finished ground level adjoining the building at all exterior walls. Where the finished ground level slopes down from the exterior walls, the grade plane shall be established by the lowest points within the area between the building and the lot line or, where the lot line is more than 6 ft (1.8 m) from the building, between the building and a point 6 ft (1.8 m) from the building.

The provision of **4.6.15** is new to the 2015 edition of the Code. It includes what had previously been a requirement within the definition of the term *grade plane* in **Chapter 3**. See the commentary that follows **3.3.126.1** for illustrations of determining grade plane and first story above grade plane for an example building.

## 4.7\* Fire Drills

**A.4.7** The purpose of emergency egress and relocation drills is to educate the participants in the fire safety features of the building, the egress facilities available, and the procedures to be followed. Speed in emptying buildings or relocating occupants, while desirable, is not the only objective. Prior to an evaluation of the performance of an emergency egress and relocation drill, an opportunity for instruction and practice should be provided. This educational opportunity should be presented in a nonthreatening manner, with consideration given to the prior knowledge, age, and ability of audience.

The usefulness of an emergency egress and relocation drill, and the extent to which it can be performed, depends on the character of the occupancy.

In buildings where the occupant load is of a changing character, such as hotels or department stores, no regularly organized emergency egress and relocation drill is possible. In such cases, the emergency egress and relocation drills are to be limited to the regular employees, who can be thoroughly schooled in the proper procedure and can be trained to properly direct other occupants of the building in case of emergency evacuation or relocation. In occupancies such as hospitals, regular employees can be rehearsed in the proper procedure in case of fire; such training is always advisable in all occupancies, regardless of whether regular emergency egress and relocation drills can be held.

Subsections **4.7.1** through **4.7.6** and the associated material from Annex A serve as a primer on how to conduct an emergency egress and relocation drill. The **\_\_\_7** section, Operating Features, of some of the occupancy chapters provides emergency egress and relocation drill details that directly correlate a drill with the characteristics of the occupancy. An understanding of how the drill details have been matched to the needs of the occupants can be gained by comparing **14.7.2** and **15.7.2** (educational occupancies emergency egress drills) with **18.7.1** and **19.7.1** (health care occupancies evacuation and relocation plan and fire drills).

**Exhibit 4.8** depicts occupants evacuating a building via exit stairs during a fire drill at NFPA headquarters.

**4.7.1 Where Required.** Emergency egress and relocation drills conforming to the provisions of this Code shall be conducted as specified by the provisions of **Chapters 11** through **43**, or by appropriate action of the authority having jurisdiction. Drills shall be designed in cooperation with the local authorities.

**Exhibit 4.8***Occupant evacuation via exit stairs during a fire drill.*

**4.7.2\* Drill Frequency.** Emergency egress and relocation drills, where required by [Chapters 11](#) through [43](#) or the authority having jurisdiction, shall be held with sufficient frequency to familiarize occupants with the drill procedure and to establish conduct of the drill as a matter of routine. Drills shall include suitable procedures to ensure that all persons subject to the drill participate.

**A.4.7.2** If an emergency egress and relocation drill is considered merely as a routine exercise from which some persons are allowed to be excused, there is a grave danger that, in an actual emergency, the evacuation and relocation will not be successful. However, there might be circumstances under which all occupants do not participate in an emergency egress and relocation drill; for example, infirm or bedridden patients in a health care occupancy.

**4.7.3 Orderly Evacuation.** When conducting drills, emphasis shall be placed on orderly evacuation rather than on speed.

**4.7.4\* Simulated Conditions.** Drills shall be held at expected and unexpected times and under varying conditions to simulate the unusual conditions that can occur in an actual emergency.

**A.4.7.4** Fire is always unexpected. If the drill is always held in the same way at the same time, it loses much of its value. When, for some reason during an actual fire, it is not possible to follow the usual routine of the emergency egress and relocation drill to which occupants have become accustomed, confusion and panic might ensue. Drills should be carefully planned to simulate actual fire conditions. Not only should drills be held at varying times, but different means of exit or relocation areas should be used, based on an assumption that fire or smoke might prevent the use of normal egress and relocation avenues.

**4.7.5 Relocation Area.** Drill participants shall relocate to a predetermined location and remain at such location until a recall or dismissal signal is given.

**4.7.6\*** A written record of each drill shall be completed by the person responsible for conducting the drill and maintained in an approved manner.

**A.4.7.6** The written record required by this paragraph should include such details as the date, time, participants, location, and results of that drill.

---

## 4.8 Emergency Action Plan

**4.8.1 Where Required.** Emergency action plans shall be provided as follows:

- (1) Where required by the provisions of [Chapters 11](#) through [42](#)
- (2) Where required by action of the authority having jurisdiction

The requirement for an emergency action plan can take either of the following forms:

1. An occupancy chapter can require an emergency action plan; for example, see [18.7.1.1](#), [19.7.1.1](#), [18.7.2.2](#) and [19.7.2.2](#), applicable to health care occupancies.
2. The authority having jurisdiction can require such plans in accordance with [4.8.1\(2\)](#).

### 4.8.2 Plan Requirements.

**4.8.2.1\*** Emergency action plans shall include the following:

- (1) Procedures for reporting of emergencies
- (2) Occupant and staff response to emergencies
- (3)\* Evacuation, relocation, and shelter-in-place procedures appropriate to the building, its occupancy, emergencies, and hazards
- (4) Appropriateness of the use of elevators
- (5) Design and conduct of fire drills
- (6) Type and coverage of building fire protection systems
- (7) Other items required by the authority having jurisdiction

**A.4.8.2.1** Items to be considered in preparing an emergency action plan should include the following:

- (1) Purpose of plan
- (2) Building description, including certificate of occupancy
- (3) Appointment, organization, and contact details of designated building staff to carry out the emergency duties
- (4) Identification of events (man-made and natural) considered life safety hazards impacting the building
- (5) Responsibilities matrix (role-driven assignments)
- (6) Policies and procedures for those left behind to operate critical equipment

- (7) Specific procedures to be used for each type of emergency
- (8) Requirements and responsibilities for assisting people with disabilities
- (9) Procedures for accounting for employees
- (10) Training of building staff, building emergency response teams, and other occupants in their responsibilities
- (11) Documents, including diagrams, showing the type, location, and operation of the building emergency features, components, and systems
- (12) Practices for controlling life safety hazards in the building
- (13) Inspection and maintenance of building facilities that provide for the safety of occupants
- (14) Conducting fire and evacuation drills
- (15) Interface between key building management and emergency responders
- (16) Names or job titles of persons who can be contacted for further information or explanation of duties
- (17) Post-event (including drill) critique/evaluation, as addressed in 5.14 of *NFPA 1600, Standard on Disaster/Emergency Management and Business Continuity Programs*
- (18) Means to update the plan, as necessary

A lesson learned from the September 11, 2001, terrorist attacks on the World Trade Center towers in New York City and the Pentagon building in Arlington, Virginia, is the importance of having a detailed emergency action plan that is tailored to the building and its occupants. The 18 topics listed in A.4.8.2.1 as requiring attention in the development of an emergency action plan broadly cover the needed facets of such a plan.

**A.4.8.2.1(3)** It is assumed that a majority of buildings will use a total evacuation strategy during a fire. It should be noted that evacuation from a building could occur for reasons other than a fire, but such other reasons are not the primary focus of the *Code*. As used herein, total evacuation is defined as the process in which all, or substantially all, occupants leave a building or facility in either an unmanaged or managed sequence or order. An

alternative to total evacuation is partial evacuation, which can be defined as the process in which a select portion of a building or facility is cleared or emptied of its occupants while occupants in other portions mostly carry on normal activity. In either case, the evacuation process can be ordered or managed in accordance with an established priority in which some or all occupants of a building or facility clear their area and utilize means of egress routes. This is typically done so that the more-endangered occupants are removed before occupants in less-endangered areas. Alternative terms describing this sequencing or ordering of evacuation are *staged evacuation* and *phased evacuation*.

**Table A.4.8.2.1(3)** illustrates options for extent of management and extent of evacuation. Some of the options shown might not be appropriate. As noted in **Table A.4.8.2.1(3)**, either total or partial evacuation can include staged (zoned) evacuation or phased evacuation, which is referred to as managed or controlled evacuation. It should also be noted that the evacuation process might not include relocation to the outside of the building but might instead include relocation to an area of refuge or might defend the occupants in place to minimize the need for evacuation.

The different methods of evacuation are also used in several contexts throughout the *Code*. Though most of the methods of evacuation are not specifically defined or do not have established criteria, various sections of the *Code* promulgate them as alternatives to total evacuation. The following sections discuss these alternatives in more detail:

- (1) **Section 4.7** — Provides requirements for fire and relocation drills
- (2) **7.2.12** — Provides requirements for area of refuge
- (3) **7.2.4** — Provides requirements for horizontal exits
- (4) **9.6.3.6** — Provides the alarm signal requirements for different methods of evacuation
- (5) **9.6.3.9** — Permits automatically transmitted or live voice evacuation or relocation instructions to occupants and requires them in accordance with *NFPA 72, National Fire Alarm and Signaling Code*

**Table A.4.8.2.1(3) Occupant Evacuation Strategies**

	Managed Sequence	Unmanaged Sequence
Shelter in place	No movement — Shelter in place upon direction	No movement — Shelter in place per prior instruction
Relocation or partial evacuation	Managed or controlled partial evacuation In-building relocation on same floor In-building relocation to different floors Occupants of some floors leave building	Unmanaged movement
Total evacuation	Managed or controlled total evacuation	Unmanaged or controlled total evacuation

- (6) 14.3.4.2.3 (also Chapter 15) — Describes alternative protection systems in educational occupancies
- (7) 18.1.1.2/18.1.1.3/Section 18.7 (also Chapter 19) — Provide methods of evacuation for health care occupancies
- (8) Chapters 22 and 23 — Provide methods of evacuation for detention and correctional occupancies, including the five groups of resident user categories
- (9) Chapters 32 and 33 — Provide methods of evacuation for residential board and care occupancies
- (10) 32.1.5/33.1.5 — For residential board and care occupancies, state that “no means of escape or means of egress shall be considered as complying with the minimum criteria for acceptance, unless emergency evacuation drills are regularly conducted”
- (11) 40.2.5.2.2 — For industrial occupancies, states that “ancillary facilities in special-purpose industrial occupancies where delayed evacuation is anticipated shall have not less than a 2-hour fire resistance–rated separation from the predominant industrial occupancy and shall have one means of egress that is separated from the predominant industrial occupancy by 2-hour fire resistance–rated construction”

The method of evacuation should be accomplished in the context of the physical facilities, the type of activities undertaken, and the provisions for the capabilities of occupants (and staff, if available). Therefore, in addition to meeting the requirements of the *Code*, or when establishing an equivalency or a performance-based design, the following recommendations and general guidance information should be taken into account when designing, selecting, executing, and maintaining a method of evacuation:

- (1) When choosing a method of evacuation, the available safe egress time (ASET) must always be greater than the required safe egress time (RSET).
- (2) The occupants’ characteristics will drive the method of evacuation. For example, occupants might be incapable of evacuating themselves because of age, physical or mental disabilities, physical restraint, or a combination thereof. However, some buildings might be staffed with people who could assist in evacuating. Therefore, the method of evacuation is dependent on the ability of occupants to move as a group, with or without assistance. For more information, see the definitions under the term *Evacuation Capability* in Chapter 3.
- (3) An alternative method of evacuation might or might not have a faster evacuation time than a total evacuation. However, the priority of evacuation should be such that the occupants in the most danger are given a higher priority. This prioritization will ensure that occupants more intimate with the fire will have a faster evacuation time.
- (4) Design, construction, and compartmentation are also variables in choosing a method of evacuation. The design, construction, and compartmentation should limit the development and spread of a fire and smoke and reduce the need for occupant evacuation. The fire should be limited to the room or compartment of fire origin. Therefore, the following factors need to be considered:
  - (a) Overall fire resistance rating of the building
  - (b) Fire-rated compartmentation provided with the building
  - (c) Number and arrangement of the means of egress
- (5) Fire safety systems should be installed that complement the method of evacuation and should include consideration of the following:
  - (a) Detection of fire
  - (b) Control of fire development
  - (c) Confinement of the effects of fire
  - (d) Extinguishment of fire
  - (e) Provision of refuge or evacuation facilities, or both
- (6) One of the most important fire safety systems is the fire alarm and communication system, particularly the notification system. The fire alarm system should be in accordance with *NFPA 72, National Fire Alarm and Signaling Code*, and should take into account the following:
  - (a) Initial notification of only the occupants in the affected zone(s) (e.g., zone of fire origin and adjacent zones)
  - (b) Provisions to notify occupants in other unaffected zones to allow orderly evacuation of the entire building
  - (c) Need for live voice communication
  - (d) Reliability of the fire alarm and communication system
- (7) The capabilities of the staff assisting in the evacuation process should be considered in determining the method of evacuation.
- (8) The ability of the fire department to interact with the evacuation should be analyzed. It is important to determine if the fire department can assist in the evacuation or if fire department operations hinder the evacuation efforts.
- (9) Evacuation scenarios for hazards that are normally outside of the scope of the *Code* should be considered to the extent practicable. (See 4.3.1.)
- (10) Consideration should be given to the desire of the occupants to self-evacuate, especially if the nature of the building or the fire warrants evacuation in the minds of the occupants. Self-evacuation might also be initiated by communication between the occupants themselves through face-to-face contact, mobile phones, and so forth.
- (11) An investigation period, a delay in the notification of occupants after the first activation of the fire alarm, could help to reduce the number of false alarms and unnecessary evacuations. However, a limit to such a delay should be established before a general alarm is sounded, such as positive alarm sequence, as defined in *NFPA 72, National Fire Alarm and Signaling Code*.
- (12) Consideration should be given to the need for an evacuation that might be necessary for a scenario other than a fire (e.g., bomb threat, earthquake).

- (13) Contingency plans should be established in the event the fire alarm and communication system fail, which might facilitate the need for total evacuation.
- (14) The means of egress systems should be properly maintained to ensure the dependability of the method of evacuation.
- (15) Fire prevention policies or procedures, or both, should be implemented that reduce the chance of a fire (e.g., limiting smoking or providing fire-safe trash cans).
- (16) The method of evacuation should be properly documented, and written forms of communication should be provided to all of the occupants, which might include sign postings throughout the building. Consideration should be given to the development of documentation for an operation and maintenance manual or a fire emergency action plan, or both.
- (17) Emergency egress drills should be performed on a regular basis. For more information, see [Section 4.7](#).
- (18) The authority having jurisdiction should also be consulted when developing the method of evacuation.

Measures should be in place and be employed to sequence or control the order of a total evacuation, so that such evacuations proceed in a reasonably safe, efficient manner. Such measures include special attention to the evacuation capabilities and needs of occupants with disabilities, either permanent or temporary. For comprehensive guidance on facilitating life safety for such populations, go to [www.nfpa.org](http://www.nfpa.org). For specific guidance on emergency stair travel devices, see ANSI/RESNA ED-1, *Emergency Stair Travel Devices Used by individuals with Disabilities*.

In larger buildings, especially high-rise buildings, it is recommended that all evacuations — whether partial or total — be managed to sequence or control the order in which certain occupants are evacuated from their origin areas and to make use of available means of egress. In high-rise buildings, the exit stairs, at any level, are designed to accommodate the egress flow of only a very small portion of the occupants — from only one or a few stories, and within a relatively short time period — on the order of a few minutes. In case of a fire, only the immediately affected floor(s) should be given priority use of the means of egress serving that floor(s). Other floors should then be given priority use of the means of egress, depending on the anticipated spread of the fire and its combustion products and for the purpose of clearing certain floors to facilitate eventual fire service operations. Typically, this means that the one or two floors above and below a fire floor will have secondary priority immediately after the fire floor. Depending on where combustion products move — for example, upward through a building with cool-weather stack effect — the next priority floors will be the uppermost occupied floors in the building.

Generally, in order to minimize evacuation time for most or all of a relatively tall building to be evacuated, occupants from upper floors should have priority use of exit stairs. For people descending many stories of stairs, this priority will maximize

their opportunity to take rest stops without unduly extending their overall time to evacuate a building. Thus, the precedence behavior of evacuees should be that people already in an exit stair should normally not defer to people attempting to enter the exit stair from lower floors, except for those lower floors most directly impacted by a fire or other imminent danger. Notably, this is contrary to the often observed behavior of evacuees in high-rise building evacuations where lower floor precedence behavior occurs. (Similarly, in the most commonly observed behavior of people normally disembarking a passenger airliner, people within the aisle defer to people entering the aisle, so that the areas closest to the exit typically clear first.) Changing, and generally managing, the sequence or order in which egress occurs will require effectively informing building occupants and evaluating resulting performance in a program of education, training, and drills.

When designing the method of evacuation for a complex building, all forms of egress should be considered. For example, consideration could be given to an elevator evacuation system. An elevator evacuation system involves an elevator design that provides protection from fire effects so that elevators can be used safely for egress. See [7.2.13](#) and [A.7.2.12.2.4](#) for more information.

- (2) *NFPA Fire Protection Handbook*, 20th edition, Section 1, Chapter 9, which provides good methodology for managing exposures and determining the method of evacuation
- (3) *NFPA Fire Protection Handbook*, 20th edition, Section 20, which provides further commentary on methods of evacuation for different occupancies
- (4) *SFPE Handbook of Fire Protection Engineering*, Section 3, Chapters 11–13, which provide an overview of some of the research on methods of evacuation and methods for predicting evacuation times

The text of [A.4.8.2.1\(3\)](#) serves as a primer on the subject of evacuation strategies. A wide range of strategies is offered, running the gamut from total evacuation to partial evacuation to sheltering in place without evacuation. For any given building and its occupants, no one evacuation strategy fits all possible emergencies. An effective action plan calls for more than one evacuation strategy and a way to communicate to occupants at the time of an emergency the strategy that is to be employed.

**4.8.2.2** Required emergency action plans shall be submitted to the authority having jurisdiction for review.

**4.8.2.3\*** Emergency action plans shall be reviewed and updated as required by the authority having jurisdiction.

**A.4.8.2.3** Emergency action plans are a critical component of assuring life safety in buildings. Life safety is the result of an interaction of technical and social systems within the building and in the community. Gathering information to evaluate the performance and effectiveness of emergency action plans is important for verifying system performance and as a basis for improvement. Such reports should be retained by building management and used to inform the process for revision of the building emergency action plan.

Following any drill or actual emergency or reported emergency occurring in the building, an after action report should be prepared by the building owner or designated representative to document the function of the building's life safety hardware, procedures, and occupant emergency organization.

For ordinary drills and reported emergencies, areas of success and areas for improvement should be identified.

For actual emergencies in the building, where there is major occupant movement, damage, or casualties, additional information should be collected. This includes questions concerning the event, as well as performance of life safety systems. It also

identifies improvements in areas such as training, maintenance, interaction with local emergency response organizations, or occupant management. The reports from these significant events should be shared with the local emergency response organization.

No one generic emergency action plan can adequately address the needs of all buildings. The AHJ has great latitude in establishing requirements that will result in the creation and upkeep of an emergency action plan tailored to the needs of the facility.

The text of **A.4.8.2.3** is new to the 2015 edition of the *Code*. Lessons learned from emergency relocation or evacuation drills, and lessons learned from actual fire incidents that necessitate emergency relocation or evacuation, should become inputs to an improved, more-customized emergency action plan.

# Performance-Based Option

Chapter 5 provides a performance-based alternative to the prescriptive provisions. This performance-based option is a process that can be used to determine whether the building design satisfies the fire safety goals and objectives specified in the Code. This chapter is not intended to replace the prescriptive Code; however, it can be used instead of the prescriptive requirements. The performance-based option provides for design flexibility.

Design flexibility was incorporated, via a performance-based design, into the Stratosphere Tower in Las Vegas, Nevada. The tower, depicted in Exhibit 5.1, opened in 1996. It rises over 900 ft (274 m) above grade with two unoccupied refuge floors, eight occupied levels, and outdoor amusement rides in the “pod,” the upper portion of the tower. At the base of the tower is a casino building. Occupied floors of the pod include two levels of observation deck, a restaurant, a meeting room level, wedding chapels, and a bar level. The top level hosts amusement rides.

The most obvious occupancy concern in the design of Stratosphere Tower was providing for emergency evacuation,

considering that the lowest occupied floor is 795 ft (242 m) above grade. Some floors of the structure were expected to accommodate an occupant load in excess of 500 people. Strict adherence to the applicable codes would have required three remote exit stairs leading from the top of the tower to the base of the building. The physical area of the supporting structure is not large enough to provide remotely located stairs in accordance with the applicable codes, and the height of the building makes the use of stairs as a means of evacuation somewhat impractical. Performance-based design concepts were employed to develop a workable evacuation strategy.

The primary evacuation method for Stratosphere Tower is the use of typical exit stairs for the occupied floors discharging to areas of refuge on the lowest two floors of the pod. In other words, from floors 3 through 10 of the pod, three exit stairs are provided, enclosed in 2-hour fire resistance-rated construction, just as would be found in most other high-rise buildings. However, these exit stairs discharge to areas of refuge at the lowest two levels of the pod, which is still 750 ft (230 m) above grade. These two areas of refuge are used for no other purpose and consist entirely of noncombustible construction. Rather than rely on mechanical systems to maintain the areas of refuge free of smoke in the event of a fire, the two floors are open to the surrounding exterior environment so that natural ventilation occurs. Since the two areas are below the occupied levels, it is unlikely that a fire in an occupied level would spread to the areas of refuge. Additionally, all the floors, including the areas of refuge, are provided with sprinkler, standpipe, detection, and alarm systems, further reducing the likelihood of downward fire spread.

From the area of refuge, a single stair leads down through the shaft of the tower to grade. The primary evacuation route from the area of refuge involves the elevators. These elevators are two-level (i.e., stacked cars) elevators that travel at a speed of up to 1800 feet per minute (9.1 meters per second) and can discharge either within the main casino or at two specially designed discharge levels at the roof of the base building. These discharge levels are enclosed in 2-hour fire resistance-rated construction from the roof to grade and are separated from all other areas by 2-hour fire resistance-rated construction.

The elevator evacuation system is capable of moving the maximum 2600-person occupant load of the pod to the base building in under 1 hour while using only three of the four two-level elevators. The fourth two-level elevator is assumed to be in use by emergency responders. When an elevator is out of service, the occupant load of the pod is limited so that the remaining elevators are capable of evacuating the pod in not more than 1 hour.

Exhibit 5.1

Stratosphere Tower, which employed performance-based design in its evacuation strategy. (© Julian Fletcher, Dreamstime.com)

In summary, Stratosphere Tower utilizes a fire protection strategy that departs from the typical building, fire, and life safety code approach to a building. Use of stairs as the sole evacuation method was not feasible or reasonable. Requiring all of the occupants to utilize stairs would result in an unsafe condition for many of the expected occupants of this building. A more reasonable method was to provide a refuge area where people could be staged until evacuated and a reliable means to perform that evacuation. The performance-based design approach provides protection in accordance with the overall intent of the building, fire, and life safety codes, while departing significantly from the prescription-based requirements of those codes.

## 5.1 General Requirements

**5.1.1\* Application.** The requirements of this chapter shall apply to life safety systems designed to the performance-based option permitted by 4.4.1 and 4.4.3.

Performance-based design has been used in the development of fire safety designs for unique architectural problems not anticipated by the current Code. The performance-based option requires the designer and the authority having jurisdiction (AHJ) to agree on the interpretation of the Code in terms of goals, objectives, desired levels of safety, appropriate fire scenarios, assumptions, and safety factors. The performance-based option in this chapter addresses these issues explicitly while also presenting information regarding the selection of appropriate calculation methods and input values. Additionally, this chapter outlines a documentation procedure that improves the transmission of information from the designer to the AHJ, thereby aiding in the approval of safe, cost-effective designs.

Many of the concepts in this chapter were not addressed in pre-2000 editions of codes or standards. For this reason, simple illustrative examples are provided to give the user a better idea of the concepts being discussed. The examples are generally based on specific building occupancies, but the concepts and ideas presented should be applicable across a range of occupancies.

**A.5.1.1 Chapter 5** provides requirements for the evaluation of a performance-based life safety design. The evaluation process is summarized in **Figure A.5.1.1**.

**Code Criteria.** On the left side of **Figure A.5.1.1** is input from the Code. The life safety goals have been stated in **Section 4.1**. The objectives necessary to achieve these goals are stated in **Section 4.2**. **Section 5.2** specifies the performance criteria that are to be used to determine whether the objectives have been met.

**Input.** At the top of **Figure A.5.1.1** is the input necessary to evaluate a life safety design.

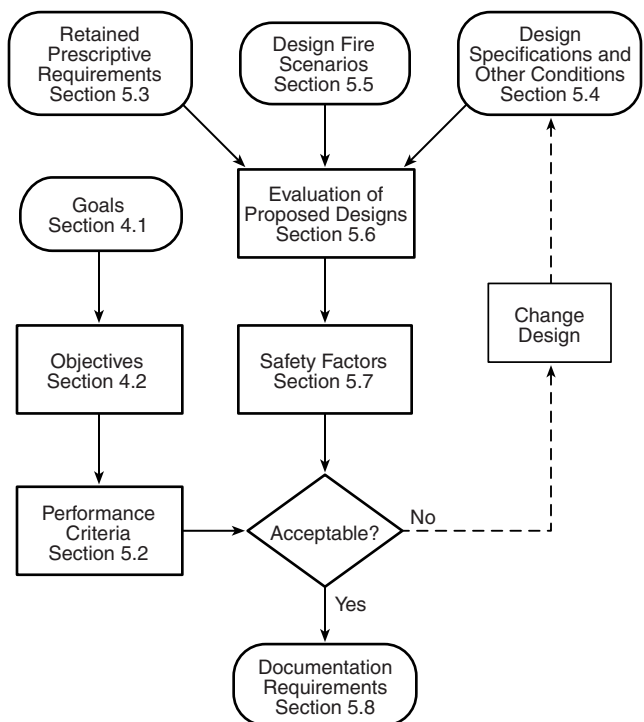

The design specifications are to include certain retained prescriptive requirements, as specified in **Section 5.3**. All

assumptions about the life safety design and the response of the building and its occupants to a fire are to be clearly stated as indicated in **Section 5.4**. Scenarios are used to assess the adequacy of the design. Eight sets of initiating events are specified for which the ensuing outcomes are to be satisfactory.

**Performance Assessment.** Appropriate methods for assessing performance are to be used per **Section 5.6**. Safety factors are to be applied to account for uncertainties in the assessment, as stated in **Section 5.7**. If the resulting predicted outcome of the scenarios is bounded by the performance criteria, the objectives have been met, and the life safety design is considered to be in compliance with this Code. Although not part of this Code, a design that fails to comply can be changed and reassessed, as indicated on the right side of **Figure A.5.1.1**.

**Documentation.** The approval and acceptance of a life safety design are dependent on the quality of the documentation of the process. **Section 5.8** specifies a minimum set of documentation that is to accompany a submission.

The performance option of this Code establishes acceptable levels of risk to occupants of buildings and structures as addressed in **Section 1.1**. While the performance option of this Code does contain goals, objectives, and performance criteria necessary to provide an acceptable level of risk to occupants, it does not describe how to meet the goals, objectives, and performance criteria. Design and engineering are needed to develop solutions that meet the provisions of **Chapter 5**. The *SFPE Engineering*

**Figure A.5.1.1** Performance-Based Life Safety Code Compliance Process.

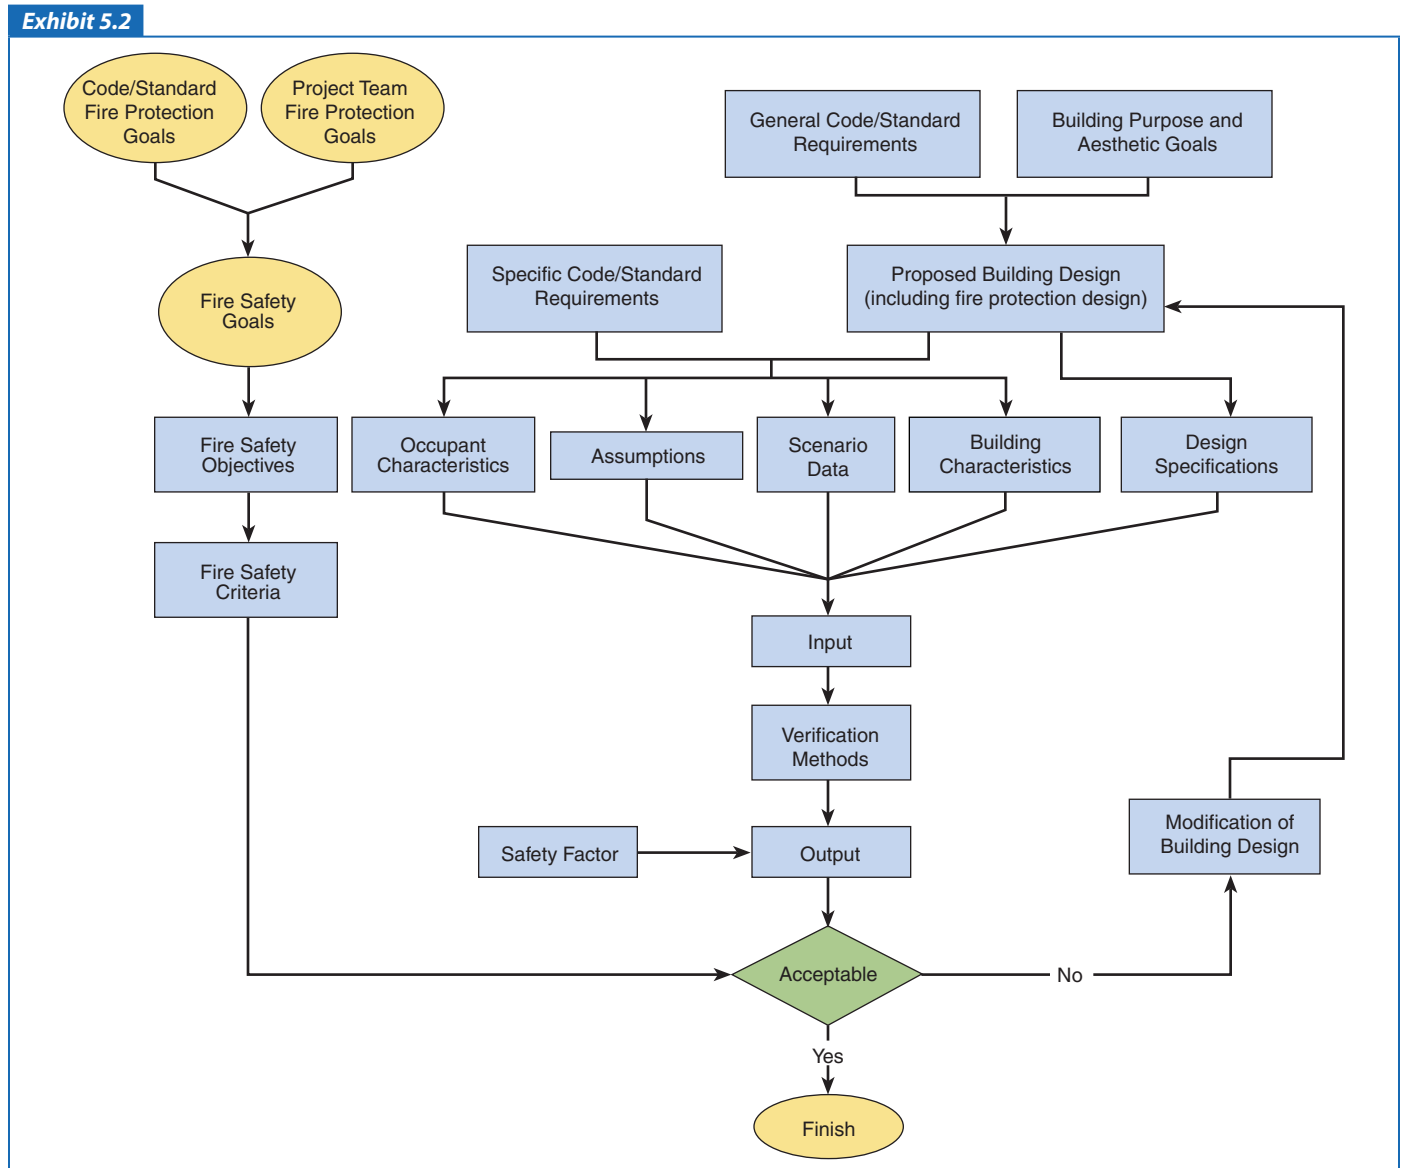

*Guide to Performance-Based Fire Protection* provides a framework for these assessments. Other useful references include the *Australian Fire Engineering Guidelines* and the *British Standard Firesafety Engineering in Buildings*.

**Exhibit 5.2** provides a tool for guidance through a performance-based design. **Exhibit 5.2** follows the same pattern as **Figure A.5.1.1**, with the *Code*-specified goals, objectives, and criteria on the left side of the chart, but it provides more detail on how the general and specific requirements included in this *Code* are used to formulate the various aspects of the design input. Several aspects of the design input are covered in various sections of this chapter, while others are developed or determined by the design team on the basis of the proposed building design. Once

completed, the design input is then used with the chosen verification methods to obtain design output, to which a safety factor is applied. After applying the safety factor, the output can be compared to the fire safety criteria to determine whether the design passes or fails, after which the building design either is submitted for approval or is re-evaluated after modifications are made to satisfy the criteria.

**5.1.2 Goals and Objectives.** The performance-based design shall meet the goals and objectives of this *Code* in accordance with **Sections 4.1** and **4.2**.

**5.1.3 Qualifications.** The performance-based design shall be prepared by a registered design professional.

Performance-based design process.

The qualifications needed by designers who develop performance-based designs are varied. Currently no certification or credential exists that formally identifies an individual as being capable of adequately developing performance-based designs. The best a code can do is to require performance-based designs to be prepared by a registered design professional. It is then left to the states and other governmental bodies to regulate the responsibilities of each registered design professional.

**5.1.4\* Independent Review.** The authority having jurisdiction shall be permitted to require an approved, independent third party to review the proposed design and provide an evaluation of the design to the authority having jurisdiction.

**A.5.1.4** A third-party reviewer is a person or group of persons chosen by the authority having jurisdiction to review proposed performance-based designs. The *SFPE Guidelines for Peer Review in the Fire Protection Design Process* provides a method for the initiation, scope, conduct, and report of a peer review of a fire protection engineering design.

The owner or developer may include a fee for third-party review in the budget for a performance-based project. This fee does not indicate that the third-party reviewer is responsible or beholden to the owner. The owner provides the funds for the authority having jurisdiction to hire a third-party reviewer, who then provides all findings to the AHJ. A similar provision, allowing the AHJ to request technical assistance with evaluating any feature or system required by this *Code* prior to granting approval, appears in 4.6.1.4.

**5.1.5 Sources of Data.** Data sources shall be identified and documented for each input data requirement that must be met using a source other than a design fire scenario, an assumption, or a building design specification. The degree of conservatism reflected in such data shall be specified, and a justification for the source shall be provided.

**5.1.6\* Final Determination.** The authority having jurisdiction shall make the final determination as to whether the performance objectives have been met.

**A.5.1.6** For guidance on reviewing performance-based designs, see the *SFPE Code Official's Guide to Performance-Based Design Review*. Additional guidance on reviewing designs in which fire risk assessment is used can be found in NFPA 551, *Guide for the Evaluation of Fire Risk Assessments*.

**5.1.7\* Maintenance of Design Features.** The design features required for the building to continue to meet the performance goals and objectives of this *Code* shall be maintained for the life of the building. Such performance goals and objectives shall include complying with all documented assumptions and design specifications. Any variations shall require the approval of the authority having jurisdiction prior to the actual change. (See also 4.6.9.2.)

**A.5.1.7** Continued compliance with the goals and objectives of the *Code* involves many factors. The building construction — including openings, interior finish, and fire- and smoke-resistive construction — and the building and fire protection systems need to retain at least the same level of performance as is provided for the original design parameters. The use and occupancy should not change to the degree that assumptions made about the occupant characteristics, combustibility of furnishings, and existence of trained personnel are no longer valid. In addition, actions provided by other personnel, such as emergency responders, should not be diminished below the documented assumed levels. Also, actions needed to maintain reliability of systems at the anticipated level need to meet the initial design criteria.

The long-term maintenance of a performance-based design is an issue that has been deemed noteworthy but for which a general solution has not been identified, due to the limited experience with performance-based designs to date. Long-term maintenance is essentially a management-of-change issue. On approval of the performance-based (building) design, it becomes a *de facto* building-specific code. As such, the provisions of the design must be maintained for the lifetime of the building. New Zealand has dealt with this issue by using independent qualified persons (IQPs) who annually certify whether a building remains compliant after a certificate of occupancy has been issued. See 4.6.9.2, which requires a yearly warrant of fitness for buildings for which performance-based design was utilized.

#### **Example: Maintenance of Design Features**

In 5.1.7, the *Code* requires that the design features of the building be maintained for the life of the building. The design features that might be modified include the following:

1. Occupancy and use of the structure
2. Design specifications
3. Assumptions made by the design team regarding the building conditions, emergency response personnel, or staff assistance
4. Characteristics of the building and occupants

The example that follows shows how great an impact a minor change can have on the design input of a performance-based design. The example does not involve a change in the occupancy of the building, but simply a change in building use. The building in question is an educational facility, originally designed and used as a high school but currently being modified for use as a kindergarten through grade 3 elementary school.

This type of change in building use does not require major reconstruction (see Chapter 43) to the building structure; however, the shops and labs in the high school would have to be converted into spaces that normally are used in an elementary school, such as classrooms, offices, or storage space. Outside of these modified spaces, the design specifications remain the same. Additionally, many of the assumptions remain unchanged,

such as the worst-case time for ignition, the ambient temperature, or the status of the ventilation system. However, changes are required in the characteristics used as design input.

The designer overseeing the change in building use needs to re-evaluate occupant characteristics, based on the fact that the building was designed with the typical occupant falling into the 14- to 18-year-old category. Now the typical occupant age will range from about 4 to 8 years old. This change may lead to differences in movement speed, reaction time, and type of reaction. Additionally, the designer might have to make changes in the location and number of occupants considered in the evaluation, based on the new use. Additional changes would have to be made regarding the need for, and level of, staff assistance.

Changes might also be required in building characteristics, such as the fuel load. The change in building use could lead to differences in the amount and type of fuel. More items geared toward young children might or might not mean additional faster-burning materials. The building might no longer contain shop or lab areas, which act as a fire hazard, but it might have additional storage space, which can add significantly to the fuel load. The designer should investigate the impact of the different fuel loads on the two building uses.

Based on the specific building, there may be additional factors that have to be modified in the design input before the building is re-evaluated. No matter how small the reuse and rehabilitation project might be, the building stakeholders should ensure that the building performance remains at a level that meets the performance goals and objectives. This re-evaluation might simply entail verifying that the new value for part of the design input is still within the allowable range, or it might entail a complete re-evaluation of the structure. In either case, the authority having jurisdiction needs to be consulted before any changes are made.

### 5.1.8 Definitions.

**5.1.8.1 General.** For definitions, see [Chapter 3](#), Definitions.

**5.1.8.2 Special Definitions.** A list of special terms used in this chapter follows:

- (1) **Alternative Calculation Procedure.** See [3.3.15](#).
- (2) **Data Conversion.** See [3.3.52](#).
- (3) **Design Fire Scenario.** See [3.3.105.1](#).
- (4) **Design Specification.** See [3.3.262.1](#).
- (5) **Design Team.** See [3.3.58](#).
- (6) **Exposure Fire.** See [3.3.88](#).
- (7) **Fire Model.** See [3.3.101](#).
- (8) **Fire Scenario.** See [3.3.105](#).
- (9) **Fuel Load.** See [3.3.164.1](#).
- (10) **Incapacitation.** See [3.3.148](#).
- (11) **Input Data Specification.** See [3.3.262.2](#).
- (12) **Occupant Characteristics.** See [3.3.191](#).
- (13) **Performance Criteria.** See [3.3.206](#).
- (14) **Proposed Design.** See [3.3.218](#).
- (15) **Safe Location.** See [3.3.235](#).
- (16) **Safety Factor.** See [3.3.236](#).
- (17) **Safety Margin.** See [3.3.237](#).
- (18) **Sensitivity Analysis.** See [3.3.17.1](#).
- (19) **Stakeholder.** See [3.3.266](#).
- (20) **Uncertainty Analysis.** See [3.3.17.2](#).
- (21) **Verification Method.** See [3.3.285](#).

## 5.2 Performance Criteria

**5.2.1 General.** A design shall meet the objectives specified in [Section 4.2](#) if, for each design fire scenario, assumption, and design specification, the performance criterion in [5.2.2](#) is met.

**5.2.2\* Performance Criterion.** Any occupant who is not intimate with ignition shall not be exposed to instantaneous or cumulative untenable conditions.

**A.5.2.2** One of the methods that follows can be used to avoid exposing occupants to untenable conditions.

**Method 1.** The design team can set detailed performance criteria that ensure that occupants are not incapacitated by fire effects. The *SFPE Engineering Guide to Performance-Based Fire Protection* describes a process of establishing tenability limits.

The guide references D. A. Purser, “Assessment of Hazards to Occupants from Smoke, Toxic Gasses, and Heat,” Chapter 2/6, *SFPE Handbook of Fire Protection Engineering*, which describes a fractional effective dose (FED) calculation approach, which is also contained in NFPA 269, *Standard Test Method for Developing Toxic Potency Data for Use in Fire Hazard Modeling*. FED addresses the effects of carbon monoxide, hydrogen cyanide, carbon dioxide, hydrogen chloride, hydrogen bromide, and anoxia. It is possible to use the test data, combined with laboratory experience, to estimate the FED value that leads to the survival of virtually all people. This value is about 0.8.

There is a relationship between exposures leading to death and those leading to incapacitation. Kaplan [Kaplan and Hartzell, *Journal of Fire Sciences*, 2:286–305 (1984)] found that rodent susceptibility is similar to that of humans and that for the narcotic gases, CO and HCN, incapacitation is estimated to occur at one-third to one-half of the lethal exposure. A set of very large statistical studies on human lethality associated with carbon monoxide involving almost 5000 fatalities (Hirschler et al., “Carbon monoxide and human lethality: Fire and non-fire studies,” Elsevier, 1993) showed that the vast majority of fire deaths are attributable to carbon monoxide poisoning, which results in lethality at levels as low as 25 percent carboxyhemoglobin (much lower than previously believed) without requiring the effect of additional toxicants. This work was also confirmed by Gann [Gann et al., *Fire and Materials*, 18:193 (1994)], who also found

that carbon monoxide dominates the lethality of fire smoke, since most fire deaths occur remote from the fire room in fires that have proceeded past flashover. Thus, if an FED value of 0.8 were used for a nonlethal exposure, an FED of 0.3 would be reasonable for a nonincapacitating exposure.

If the authority having jurisdiction or the design professional is concerned with potential toxic fire effects, other than those addressed by the FED procedure as documented, the calculation procedure can be expanded by adding additional terms to the FED equation, with each term expressed as a ratio. The numerator of the ratio is the cumulative exposure to that fire effect, measured as an integral of the product of instantaneous exposure (concentration for toxic products) and time. The denominator of the ratio is the quantity of cumulative exposure for which FED equals the chosen threshold value (i.e., 0.8 or 0.3) based on that fire effect alone. A complete analysis of tenability requires consideration of tenability criteria for thermal effects (convected heat and radiated heat) and smoke obscuration, as well as those for smoke toxicity, and an example of the application of such criteria is shown in ASTM E 2280, *Standard Guide for Fire Hazard Assessment of the Effect of Upholstered Seating Furniture Within Patient Rooms of Health Care Facilities*.

For buildings where an unusually large fraction of the occupants are especially vulnerable, the calculation procedure for the smoke toxicity incapacitating criterion should be modified to use FED values lower than 0.8 or 0.3.

**Method 2.** For each design fire scenario and the design specifications, conditions, and assumptions, the design team can demonstrate that each room or area will be fully evacuated before the smoke and toxic gas layer in that room descends to a level lower than 6 ft (1830 mm) above the floor. The timing of such an evacuation means that no occupant is exposed to fire effects. Such an evacuation requires calculation of the locations, movement, and behavior of occupants, because fire effects and occupants are separated by moving the occupants. A level of 60 in. (1525 mm) is often used in calculations, but, at that level, a large fraction of the population would not be able to stand, walk, or run normally and still avoid inhalation of toxic gases. They would have to bend over or otherwise move their heads closer to the floor level.

**Method 3.** For each design fire scenario and the design specifications and assumptions, the design team can demonstrate that the smoke and toxic gas layer will not descend to a level lower than 6 ft (1830 mm) above the floor in any occupied room. The advantage of this procedure is that it conservatively ensures that no occupant is exposed to fire effects, regardless of where occupants are located or where they move. This eliminates the need for calculations regarding occupants, including those for their behavior, movement locations, pre-fire characteristics, and reactions to fire effects. This procedure is even more conservative and simpler than the procedure in Method 2, because it does not allow fire effects in occupied rooms to develop to a point where people could be affected at any time during the fire.

**Method 4.** For each design fire scenario and the design specifications and assumptions, the design team can demonstrate that no fire effects will reach any occupied room. The advantage of this procedure is that it eliminates the need for calculations regarding occupants, including those for their behavior, movement, locations, pre-fire characteristics, and reactions to fire effects. A further advantage is that it also eliminates the need for some of the modeling of fire effects, because it is not necessary to model the filling of rooms, only the spread of fire effects to those rooms. This procedure is even more conservative and simpler than the procedures in Methods 2 and 3, because it does not allow any fire effects in occupied rooms.

The methods described in A.5.2.2 provide an indication of the variety of ways of demonstrating that a proposed design meets the performance criteria and, therefore, also meets the objectives. The methods also illustrate how different approaches can result in different margins of safety. Specifically, Methods 2, 3, and 4 are all similar in their approach — they deal with smoke filling a room. Method 2 concentrates on evacuating people before the smoke level reaches 6 ft (1830 mm) above the floor. This method presumes that the smoke will eventually reach a lower level and could, therefore, expose people crawling under the smoke layer. This method results in a relatively small margin of safety. Method 3 has a presumably more proactive design in that its intent is to prevent the smoke layer from descending any lower than 6 ft (1830 mm) above the floor. The intent of this method is to prevent exposure to occupants without their leaving the room, unless they are taller than 6 ft (1830 mm) and unwilling or unable to bend over. This method produces a greater margin of safety than that of Method 2. The margin of safety for Method 4 is the greatest — excluding the room of fire origin — because it requires the proposed design to prevent smoke from reaching any occupied room.

Three additional points are relevant to these methods. The first is that the final performance criteria might be the result of an agreement with the authority having jurisdiction, which might require or accept a threshold other than the 6 ft (1830 mm) threshold cited. In both Methods 2 and 3, a value of 7 ft (2135 mm), 6 ft 6 in. (1980 mm), or 5 ft (1525 mm) might be justified instead, based on the use of different fractions of the population requiring protection — given that some people are taller than 6 ft (1830 mm) — or the use of different safety margins based on the uncertainty calculation of the smoke layer height. The threshold for smoke layer height and other thresholds need to be a subject of discussion before beginning the performance-based design.

The second point is that Method 4 presumes that the room of fire origin is unoccupied. Depending on the facility and the scenario, this might not be a reasonable assumption. If it is not reasonable, the criteria for safety for the room of fire origin need to be set separately.

The final point, outlined in the discussion that follows, demonstrates the differences among Methods 2, 3, and 4 with respect

to the level of analysis required, not with regard to their use as a specification for performing an analysis or determining whether the design meets the performance criterion for the method. Depending on the method selected for use in the evaluation, the designer needs to perform different types and levels of analysis. If it is decided to use Method 2, which states that the smoke and toxic gas will not descend to a level lower than 6 ft (1830 mm) before the area is fully evacuated, the designer needs to model both the fire and smoke spread in the building to determine the time each space becomes untenable. Additionally, the designer needs to model each occupant's egress from the building, determining the times at which each space is occupied or fully evacuated. The models and the levels of fire and smoke spread and occupant egress can then be compared to determine if the toxic gas level and smoke descend beyond the specified level before the area is fully evacuated. This analysis path requires detailed modeling of both the toxic gas spread and the evacuation of the occupants. Care must be taken to ensure that the modeling is completed conservatively and accurately, because Method 2 does not provide a large margin for error inherent in the design.

If Method 3, which states that the smoke and toxic gas layer will not descend below 6 ft (1830 mm) in any occupied room, is selected, the analysis becomes both less complicated and more conservative. After identifying each occupied space in the building, including spaces that will be occupied during occupant egress, the analysis will consist of a determination of when and whether the smoke and toxic gas layer will descend below the specified level in these areas. While the design still needs a detailed analysis of the fire and the spread of the products of combustion to determine the level of filling in each occupied area, such an analysis need not consider the building occupants or any actions they might take before or during the emergency.

If the stakeholders wish to design the building to satisfy Method 4, which states that no fire effects will reach any occupied area, the analysis becomes even less complicated and more conservative than that of Method 3. The designer should evaluate the building for each fire scenario to determine only if the smoke and toxic products of combustion will spread beyond the room of origin to occupied areas. This process often requires less complicated design tools and verification methods, because the rate and degree of smoke movement in the building is irrelevant as long as the designer can determine whether the smoke or toxic gas will travel into occupied areas.

### 5.3 Retained Prescriptive Requirements

**5.3.1\* Systems and Features.** All fire protection systems and features of the building shall comply with applicable NFPA standards for those systems and features.

**A.5.3.1** This requirement applies both to systems and features required by the *Code* that reference applicable standards and to

any additional systems or features included in the design at the discretion of the design team. The referenced standards are hereby expected to state maintenance, testing, and other requirements needed to provide positive assurance of an acceptable level of reliability. The referenced standards themselves might be prescriptive- or performance-based.

**5.3.2 Means of Egress.** The design shall comply with the following requirements in addition to the performance criteria of [Section 5.2](#) and the methods of [Sections 5.4](#) through [5.8](#):

- (1) Changes in level in means of egress — [7.1.7](#)
- (2) Guards — [7.1.8](#)
- (3) Doors — [7.2.1](#)
- (4) Stairs — [7.2.2](#), excluding the provisions of [7.2.2.5.1](#), [7.2.2.5.2](#), [7.2.2.6.2](#), [7.2.2.6.3](#), and [7.2.2.6.4](#)
- (5) Ramps — [7.2.5](#), excluding the provisions of [7.2.5.4.1](#), [7.2.5.5](#), and [7.2.5.7.1](#)
- (6) Fire escape ladders — [7.2.9](#)
- (7) Alternating tread devices — [7.2.11](#)
- (8) Capacity of means of egress — [Section 7.3](#), excluding the provisions of [7.3.3](#) and [7.3.4](#)
- (9) Impediments to egress — [7.5.2](#)
- (10) Illumination of means of egress — [Section 7.8](#)
- (11) Emergency lighting — [Section 7.9](#)
- (12) Marking of means of egress — [Section 7.10](#)

The prescriptive provisions listed in [5.3.2](#) for the means of egress do not readily lend themselves to performance-based calculation. However, these requirements cannot be excluded from the design. Therefore, these prescriptive provisions are retained for performance-based designs. For example, prescriptive exit sign requirements help to ensure the effectiveness of the means of egress; emergency lighting along the egress path provides prescriptive reliability for the illumination needed for effective exiting. A rationale for retaining these prescriptive requirements is that existing models of evacuation behavior are not sophisticated enough to quantify the effect of signs or lighting on the speed and effectiveness of exiting behavior.

**5.3.3 Equivalency.** Equivalent designs for the features covered in the retained prescriptive requirements mandated by [5.3.2](#) shall be addressed in accordance with the equivalency provisions of [Section 1.4](#).

## 5.4 Design Specifications and Other Conditions

**5.4.1\* Clear Statement.** Design specifications and other conditions used in the performance-based design shall be clearly stated and shown to be realistic and sustainable.

**A.5.4.1** The design specifications and other conditions form the input to evaluation of proposed designs (*see Section 5.6*). Where

a specification or condition is not known, a reasonable estimation is permitted. However, the design team must take steps to ensure that the estimation is valid during the life of the building. Any estimations need to be documented. (See [Section 5.8](#).)

An example of an estimation could be a material property value needed as input by a computer fire model. Typically, computer fire models allow a single value to be input for material properties. However, if the material property varies with temperature, there is a question as to which single value adequately characterizes the material. The single value used to estimate the behavior of the material over the entire temperature range that might be experienced during the course of a fire needs to be conservatively selected and documented.

See [A.5.6](#) for more information on computer fire models.

## 5.4.2 Assumptions and Design Specifications Data.

**5.4.2.1** Each assumption and design specification used in the design shall be accurately translated into input data specifications, as appropriate for the method or model.

The documentation of the performance-based analysis needs to clearly indicate the process for converting assumptions and design specifications into input data specifications. In some cases, the conversion process is straightforward. For example, room dimensions are explicitly stated in the design specification and can be used as input data without modification. However, if the designer assumes that a certain material will be the fuel consumed by the fire, then the process of converting that assumption into a heat release rate curve, a mass loss curve, toxic potency values, a flame spread rate, or other data for modeling needs to be described.

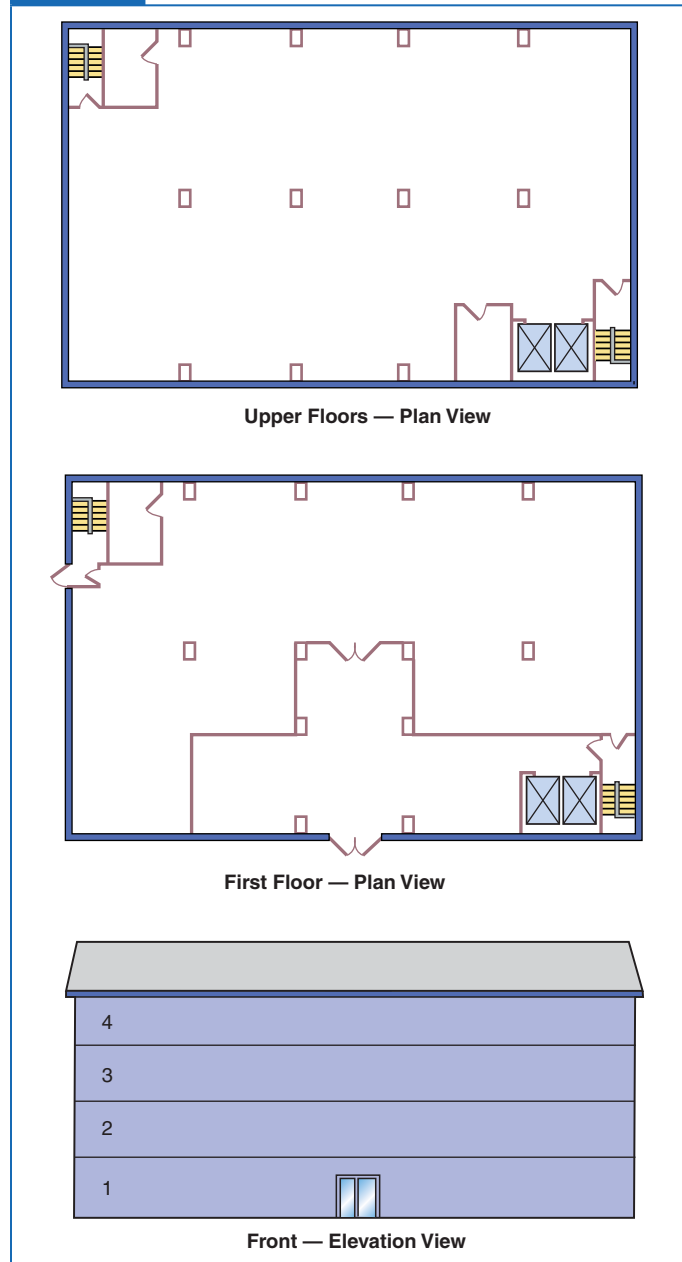

The source of much of the input data for the verification methods is the design specifications for the building. The design specifications are to include all the information from the building design that affects the ability of the building to meet the stated goals and objectives. In addition to the building plans and drawings, the design specification information is to be presented for use by the designer and the authority having jurisdiction. Both parties then review the information and implement it as input data specifications.

The simple example that follows illustrates the type of information that should be included with the design specifications.

### Example: Design Specifications

This example is based on a hypothetical, four-story business occupancy building. The example building plan is shown in [Exhibit 5.3](#), which is not drawn to scale. The fire protection and egress features for the building are not designed to meet the prescriptive *Code* requirements, with the exception of those items listed in [5.3.2](#). Additionally, the building has not been analyzed using the methods in [Chapter 5](#). To conserve time and space, the systems, features, and construction details specified in this example are not explained in full detail, since this

**Exhibit 5.3**

*Four-story business occupancy building.*

information is available from a variety of other sources. However, when completing an actual performance-based design, detailed information on each system and construction feature, such as an automatic sprinkler system or a fire barrier wall, needs to be compiled and presented for use by the designer and the authority having jurisdiction.

A description of the layout and dimensions of the building is to be developed. This description is to include a breakdown of each area to be considered in the performance-based design, as well as a description of the building as a whole.

### Building Specifications

Building footprint — 100 ft × 250 ft (30 m × 76 m)

Building height — 50 ft (15 m)

Story height (top of floor slab to bottom of slab on next floor) — 12 ft (3660 mm)

Floor height (below false ceiling) — 10 ft (3050 mm)

Steel frame construction (interior columns) — W8 × 28 steel columns protected by two layers of gypsum wallboard — total 1 in. (25 mm) thick; include design and construction details for column protection

Poured-on-deck concrete slab — 6 in. (150 mm) thick, supported by prefabricated joists

Interior finish material — gypsum wallboard

Ceiling construction — include design and fabrication details for ceiling construction and materials

Automatic sprinkler system — installed throughout per NFPA 13, *Standard for the Installation of Sprinkler Systems*<sup>1</sup>; include all specifications for sprinkler system normally included in a prescriptive system design [e.g., information relative to design density, response time index (RTI), spacing]

Alarm system — initiation by means of waterflow alarm incorporated into sprinkler system that operates when flow of water is equal to or greater than that from single sprinkler; waterflow alarm activates evacuation signal designed per NFPA 72<sup>®</sup>, *National Fire Alarm and Signaling Code*<sup>2</sup>; include all specification and design information for alarm system normally provided for a prescriptive design

HVAC system — designed and installed per NFPA 90A, *Standard for the Installation of Air-Conditioning and Ventilating Systems*,<sup>3</sup> and applicable regional plumbing and mechanical code

### Stairs

Two exit stair enclosures located in opposite corners of building

Stair enclosures — 10 ft × 25 ft (3050 mm × 7620 mm)

Stair riser height — 6 in. (150 mm)

Stair tread depth — 12 in. (305 mm)

Stair clear width — 48 in. (1220 mm)

Stairs enclosed with 2-hour fire resistance-rated barrier walls (provide design and construction details)

1½-hour fire protection-rated, self-closing, 32 in. (810 mm) clear width doors

### Elevators

Two 12 ft × 12 ft (3660 mm × 3660 mm) elevators separated from rest of building by 2-hour fire resistance-rated barrier walls (provide design and construction details)

Elevator installation per ASME A17.1/CSA B44, *Safety Code for Elevators and Escalators*<sup>4</sup>

### Storage Room — Located on Upper Floors Next to Elevator Lobby

Dimensions — 20 ft × 25 ft (6100 mm × 7620 mm)

Nonbearing walls constructed of gypsum wallboard mounted on metal studs

32 in. (810 mm) clear width self-closing door

### Rest Room — Located Adjacent to Second Stair Enclosure

Dimensions — 15 ft × 25 ft (4570 mm × 7620 mm)

Nonbearing walls constructed of gypsum wallboard mounted on metal studs

32 in. (810 mm) clear width self-closing door

### Entranceway (Ground Floor)

Separated from remainder of first floor by 2-hour fire resistance-rated barrier walls (provide design and construction details)

Two main doors for entry into office space on ground floor — 1½-hour fire protection-rated, self-closing, 40 in. (1015 mm) clear width

Two exterior exit doors off lobby — self-closing, 40 in. (1015 mm) clear width

Dimensions to be indicated on drawing

Emergency lighting and marking of means of egress — specify details and design per Code's prescriptive requirements

### Example: Assumptions

In addition to compiling building specifications, a variety of assumptions needs to be made by the designer in developing a performance-based design. These assumptions are to remain constant and consistent throughout the analysis of the building. This example is included to provide information relating to the types of assumptions that might be made for a hypothetical 15-story hotel occupancy building. Similar to the design specifications example, this information is provided in a list format. Certain assumptions made by the design team can be included with different sections of the design input, such as assumptions regarding the location of the occupants, which would be included with the occupant characteristics. Additionally, any assumptions that do not remain constant across the various scenarios cannot be classified as assumptions — they instead become scenario-related data. The breakdown of information should be agreed on with the AHJ before a design is submitted.

**Status of Ventilation System.** Information relating to the ventilation system and its status at the time of ignition should be included among the assumptions. While the design and

construction information pertaining to the ventilation system would be included in the design specifications, the assumptions relating to this system would relate purely to its status at the time of the fire — mainly whether it was on or off. Additionally, information relating to whether the ventilation system would remain on throughout the fire scenarios — or whether an automatic device would shut down the system — could be included in this data. This example assumes that the ventilation system is on and operating normally at the time of ignition.

**Ambient Temperature.** Ambient temperature is based on the anticipated condition of the building at the time of ignition. For most modern buildings, ambient temperature is dependent on the occupancy classification, since many buildings now incorporate heating/ventilation systems that maintain a constant temperature. For this example, the ambient temperature is 70°F (21°C).

**Ignition Time.** Assume worst-case time of day for the various fire scenarios. In the case of a hotel, the worst-case time is in the evening or very early morning hours, when the occupants are expected to be sleeping.

**Egress Paths.** Assumptions are to be made regarding the condition of the egress ways and whether they are clear of debris. These assumptions are generally dependent on the anticipated use of the building, as certain building types are more likely than others to have objects stored or placed in the egress paths. In this example, the assumption that each stairway is clear of clutter and debris is based on daily verification by a hotel employee. However, the lobby area — which might be used as a primary means of egress — is often cluttered with items such as luggage or chairs, and the designer needs to estimate a usable egress width.

**Mobility Impairment.** Assume one mobility-impaired occupant per floor of the structure. The mobility impairments affect the occupant characteristics of the building. The actual number of mobility-impaired individuals using the building might be based on one of the following:

1. Severity of the impairments
2. Local jurisdictional requirements
3. Selection by the design team, based on the location of the structure and the anticipated clientele
4. Number of rooms properly equipped to house mobility-impaired individuals

**Occupant Age Distribution.** Assumptions regarding the age distribution of occupants are to be made. Research has shown that groups of occupants separated by age have different movement speeds, and the design team needs to conservatively estimate the number of middle-aged adults, elderly, and children who will be located within the structure.

**System Performance.** Assume that all systems perform as designed, unless the scenario specifically mandates a system failure.

**Egress Path Selection.** Assume that all occupants will attempt to egress via the exit most familiar to them or that they will attempt to use the path followed when entering the building. Since most occupants will probably have used the elevator, assume occupants will use the first exit stair encountered in moving toward the elevators.

**Fire Fighter Staging.** Depending on the time that passes until fire fighter arrival, assume that the speed of occupant movement on stairs will be reduced by half for the stairs that the fire department uses as a staging area.

**5.4.2.2** Any assumption and design specifications that the design analyses do not explicitly address or incorporate and that are, therefore, omitted from input data specifications shall be identified, and a sensitivity analysis of the consequences of that omission shall be performed.

The term *design analyses*, as used in 5.4.2.2, means the baseline analyses of the proposed design. The design analyses are compiled into a report and submitted to the authority having jurisdiction for approval. Design specifications and assumptions would not be included in the baseline analyses if, for example, the designer originally considered incorporating an automatic suppression system into the building design or designing the building to rely on manual suppression if a fire occurs. In such a case, the designer would perform an analysis on each of those options and include in the proposed design the analysis that best satisfies the performance criteria at the lowest cost. The rejected option would be included as an appendix in the submittal to the AHJ. The appendix would indicate why the rejected option was not included in the analyses, as well as how the building performance would change if the rejected option were to be incorporated into the design.

**5.4.2.3** Any assumption and design specifications modified in the input data specifications, because of limitations in test methods or other data-generation procedures, shall be identified, and a sensitivity analysis of the consequences of the modification shall be performed.

For example, new and innovative designs for detection systems, suppression systems, or overall building layout and egress systems might be incorporated into a performance-based design. Unfortunately, while the design team may feel that these systems and modifications provide a marked improvement in the performance of the building, they might not be quantifiable in the models used to analyze the structure. If the design specifications and assumptions are such that they cannot be directly implemented into a model, the design team needs to provide justification for selection of input values to be used for the specifications and assumptions. This justification needs to include the following:

1. Detailed description of the new or modified system
2. Rationale behind the selection of the system for incorporation into the building design

3. Reason for not incorporating specifications and assumptions directly into the model input
4. Anticipated level of performance
5. Improvements expected from the system
6. Means of specifying input values in the input data specifications

Due to the level of uncertainty involved in this type of input data specification development, the design team needs to perform a sensitivity analysis on any of the input values formulated using this procedure. An example of a type of system whose design specification cannot be directly incorporated into the input data specifications is a new detection and alarm system that has not been fully tested in the arrangement and layout of the proposed building. If the design team can provide justification that the model cannot accurately predict the system's performance, then modifications should be made to the input data specification to account for the differences in the results of the analysis and the performance of the system.

**5.4.3 Building Characteristics.** Characteristics of the building or its contents, equipment, or operations that are not inherent in the design specifications, but that affect occupant behavior or the rate of hazard development, shall be explicitly identified.

Building characteristics that are not classified as design specifications tend to be limited to particular spaces within the building, occupancy- or purpose-driven, or long-term or transitory adjustments by occupants to problems in the functionality of the basic design. The building characteristics depend largely on the materials used to decorate and furnish the building and on the anticipated layout of such materials. The identification of building characteristics needs to take into account the intended use of the building and potential aging effects on the materials used. The identification of building characteristics of concern requires considerable experience with the hazard-related consequences of both typical and problematic operations in occupancies of the type proposed.

Examples of building characteristics include the anticipated layout, fuel load, and burning characteristics of a work area composed of cubicles in a business occupancy. In addition to the flammability characteristics of the interior lining materials of a structure, an additional modification could be included with the building characteristics to account for the potential buildup of combustible dust or hydrocarbon residue on the material in an industrial complex. Buildings in which there is a high rate of occupant turnover and movement, such as educational facilities or dormitories, might include doors — and more importantly, fire doors — that are routinely blocked open, allowing the uninhibited passage of smoke and other fire products of combustion. Designers of a mercantile occupancy might deliberately or inadvertently create a maze-like effect, which not only affects evacuation times but might also lead to anxiety and confusion in the occupants during an emergency.

The description of the building characteristics is to include all of the information related to the building and its various contents and features that is not included with the design specifications. Various examples of building characteristics are provided in this commentary. However, the example that follows includes a more detailed description of the types of items that should be included with the building characteristics when developing a performance-based design. Additionally, this example presents differences in, and modifications that would be required for, the building characteristics if the intended use is changed from a business occupancy to a mercantile occupancy. The different occupancy types can lead to large differences in smoke production and spread throughout the structure, as well as differences in evacuation time. The designer needs to carefully select and document the characteristics of the specific building. The designer also needs to use conservative estimates of the various building characteristics, particularly if there is a possibility that the owner might change the building type or occupancy.

#### **Example: Building Characteristics**

The building in question is a three-story office building that is being converted into a three-level department store. The specifications that follow provide a description of the building characteristics that might be used in the original performance-based design for the business occupancy.

**Office Space.** The space is divided throughout by work cubicles. A baseline case office setup for cubicle arrangement is to be specified. Arrangements are to be analyzed using sensitivity analysis to determine the allowable level of variance in office setup.

**Fuel Load.** The fuel load is dependent on office setup. A fixed fuel load is to be used, as limited types of materials are available for consumption. The fuel load will consist of materials such as office furniture, computers, cubicle finishing materials, and paper. Tests that measure the burning rate of office cubicles and different office setups are to be consulted to determine the total combined fuel load. The flammability of each potential fuel item in the area of ignition is to be estimated. Other potential sources of fuel in a business occupancy include the interior finish materials and paper or office equipment in storage areas.

The flammability information for the fuel sources, such as the heat release rate, rate of flame spread, and mass loss rate, can be determined from several sources. The flammability data for the fuels in question might be available in typical fire protection texts, such as the NFPA *Fire Protection Handbook*,<sup>5</sup> the *SFPE Handbook of Fire Protection Engineering*,<sup>6</sup> and Drysdale's *An Introduction to Fire Dynamics*.<sup>7</sup> This information can also be estimated using the results from small-scale tests, such as those from a cone calorimeter or a LIFT (lateral ignition and flamespread test) apparatus. A more accurate determination of the flammability characteristics can be produced in large-scale testing of the fuels in question. This is not to suggest that the designer conduct

large-scale testing of the anticipated fuel sources for each design; however, a review of large-scale tests completed on items similar to those in question at fire testing labs such as the National Institute of Standards and Technology (NIST) Building and Fire Research Laboratory might provide accurate estimates of the required material properties. NIST has compiled this research in reports such as “A Survey of Fuel Loads in Contemporary Office Buildings” by Caro and Milke.<sup>8</sup> These reports are available for downloading on NIST’s web site or at its research library. The flammability of the specific items in question should be documented as accurately as possible.

**Egress Paths.** Despite the variability of the office setup, business occupancies typically will have clear, fixed paths of egress. The egress paths will generally consist of a perimeter loop around the office core, along with multiple aiseways leading from the interior offices to the perimeter loop. Based on the type of business occupying the structure, the designer should determine whether the egress paths are likely to remain clear of clutter and debris. This facet of the building characteristics could also be included with the design assumptions.

**Fire Doors.** The condition of the fire doors in the structure is to be specified with the building characteristics. Business occupancies generally keep fire doors in the structure closed due to the limited need to block the doors open, since, generally, occupant turnover is not large and movement of furniture is periodic.

The building characteristics described in this commentary are assumptions relating to the building’s function. These business occupancy characteristics can be compared to those identified for the department store to determine which characteristics can be replaced with new values for the new occupancy. Generally, some differences exist; if the new characteristics vary significantly, the designer might have to re-evaluate the performance of the structure completely.

The paragraphs that follow present the types of information that are to be included with the building characteristics for the renovated mercantile occupancy spaces.

**Mercantile Space.** As in the case of the business occupancy, a baseline case setup of the mercantile space is to be specified. However, a mercantile occupancy generally modifies the arrangement and setup of the building contents more frequently than a business occupancy does, based on the type of store involved. The design is to be sufficiently robust so that almost every typical arrangement of the mercantile occupancy is permitted, with the exception of extreme cases utilizing highly volatile or flammable substances.

**Fuel Load.** The fuel load for a mercantile occupancy is based primarily on the intended merchandise. The fuel load could consist of items ranging from electronics, plastics, and food products to wood materials, upholstered furniture, and seasonal decorations. The fuel load can vary greatly, depending on the type of store and even the time of year. The design is to be based

on the worst-case fuel load that the designer believes might be contained in the building at any time.

**Egress Paths.** Many mercantile establishments either inadvertently or deliberately create maze-like paths that run through the store. While such paths might keep shoppers in the store for longer periods, causing them to view more of the merchandise, they will also cause longer evacuation times and can lead to anxiety during emergencies. Additionally, due to restocking operations and the moving of merchandise, the egress paths and aiseways in a mercantile occupancy might be partially or fully blocked.

**Fire Doors.** Mercantile occupancies are frequently moving items and storing contents and may have large occupant loads moving between different spaces. These practices might result in the fire doors within the structure being blocked open, potentially allowing smoke and other products of combustion to spread uninhibited throughout the structure. The evaluation should consider this issue, or the designer should take steps to ensure that the fire doors remain closed.

**5.4.4\* Operational Status and Effectiveness of Building Features and Systems.** The performance of fire protection systems, building features, and emergency procedures shall reflect the documented performance and reliability of the components of those systems or features, unless design specifications are incorporated to modify the expected performance.

**A.5.4.4** Systems addressed by this requirement include automatic fire suppression systems and fire alarm systems. Performance issues that need to be documented might include response time indexes, discharge densities, and distribution patterns. Calculations should not include an unlimited supply of extinguishing agent if only a limited supply will be provided in the actual structure or building.

Emergency procedures addressed by this requirement might be of two types. The design team could include documentation from buildings that are operationally very similar, along with documented operational performance measures tied to the recruitment and training of emergency team personnel. Where such data are unavailable, or where the proposed design differs significantly from other buildings, the design could be based on detailed analyses of the decisions and tasks that need to be performed by emergency personnel, using plausible conservative assumptions about the occupant characteristics and training of those personnel.

**Subsection 5.4.4 and A.5.4.4** are meant to help ensure that the performance-based design analysis is realistic and reflects the anticipated operation of the systems, including people-oriented systems like emergency procedures. In other words, the analysis must consider that the systems installed in buildings are limited — they are not like Hollywood guns that never run out of bullets. Designers need to make sure that the analysis

deals with the systems in a practical manner and is representative of how the systems will be installed in the building.

**Subsection 5.4.4** addresses inherent performance limitations more than reliability concerns, which are separately addressed in **5.5.3.8**, through mandatory analysis of scenarios with systems and features rendered unavailable. For example, there are different modes of fire detection (such as ionization smoke detectors, photoelectric smoke detectors, fixed-temperature heat detectors, and rate-of-rise heat detectors) that provide different speeds of response to different fire scenarios. Also, automatic fire sprinklers use varying design densities, resulting in different speeds and degrees of effectiveness, depending on the fire scenario. Fire doors are rated for different durations and are expected to withstand different levels of heat impact before failing. Additionally, fire barrier walls are expected to exhibit various performance levels, particularly if one wall extends from the floor to the roof, while another extends to a level below the roof. Systems related to emergency procedures are not of the “one size fits all” character. Such emergency procedures must be tailored to the specific building and occupant population.

### 5.4.5 Occupant Characteristics.

**5.4.5.1\* General.** The selection of occupant characteristics to be used in the design calculations shall be approved by the authority having jurisdiction and shall provide an accurate reflection of the expected population of building users. Occupant characteristics shall represent the normal occupant profile, unless design specifications are used to modify the expected occupant features. Occupant characteristics shall not vary across fire scenarios, except as authorized by the authority having jurisdiction.

**A.5.4.5.1** Examples of design features that might be incorporated to modify expected occupant characteristics include training, use of staff to assist with notification and movement, or type of notification appliance used.

**5.4.5.2\* Response Characteristics.** The basic response characteristics of sensibility, reactivity, mobility, and susceptibility shall be evaluated. Such evaluation shall include the expected distribution of characteristics of a population appropriate to the use of the building. The source of data for these characteristics shall be documented.

**A.5.4.5.2** The four basic characteristics — sensibility, reactivity, mobility, and susceptibility — comprise a minimum, exhaustive set of mutually exclusive performance characteristics of people in buildings that can affect a fire safety system’s ability to meet life safety objectives. The characteristics are briefly described as follows:

- (1) Sensibility to physical cues, which is the ability to sense the sounding of an alarm and can also include discernment and discrimination of visual and olfactory cues in addition to auditory emanations from the fire itself

- (2) Reactivity, which is the ability to interpret cues correctly and take appropriate action and can be a function of cognitive capacity, speed of instinctive reaction, or group dynamics; might need to consider reliability or likelihood of a wrong decision, as in situations where familiarity with the premises influences wayfinding
- (3) Mobility (speed of movement), which is determined by individual capabilities, as well as crowding phenomena, such as arching at doorways
- (4) Susceptibility to products of combustion, which includes metabolism, lung capacity, pulmonary disease, allergies, or other physical limitations that affect survivability in a fire environment

In application, as with the use of computer evacuation models, assumptions can address a larger number of factors that are components of the basic performance characteristics, including the following:

- (1) Alertness — condition of being awake/asleep, can depend on time of day
- (2) Responsiveness — ability to sense cues and react
- (3) Commitment — degree to which occupant is committed to an activity underway before the alarm
- (4) Focal point — point at which an occupant’s attention is focused (e.g., to front of classroom, stage, or server in business environment)
- (5) Physical and mental capabilities — influence on ability to sense, respond, and react to cues; might be related to age or disability
- (6) Role — influence on whether occupant will lead or follow others
- (7) Familiarity — influence of time spent in building or participation in emergency training
- (8) Social affiliation — extent to which an occupant will act/react as an individual or as a member of a group
- (9) Condition over the course of the fire — effects, both physiological and psychological, of the fire and its combustion products on each occupant

For a more detailed explanation of occupant characteristics, see the *SFPE Engineering Guide to Human Behavior in Fire*. Occupant characteristics that are discussed in the guide include the following:

- (1) Population numbers and density
- (2) Condition of being alone or with others
- (3) Familiarity with the building
- (4) Distribution and activities
- (5) Alertness
- (6) Physical and cognitive ability
- (7) Social affiliation
- (8) Role and responsibility
- (9) Location
- (10) Commitment

- (11) Focal point
- (12) Occupant condition
- (13) Gender
- (14) Culture
- (15) Age

**5.4.5.3 Location.** It shall be assumed that, in every normally occupied room or area, at least one person shall be located at the most remote point from the exits.

All occupant locations at the start of the fire must be specified. This information is critical for egress analysis, since travel distances to the exits must be known. Depending on the scenarios of interest, conditions within selected egress paths must be analyzed. However, the conditions in the room of fire origin always need to be determined.

**5.4.5.4\* Number of Occupants.** The design shall be based on the maximum number of people that every occupied room or area is expected to contain. Where the success or failure of the design is contingent on the number of occupants not exceeding a specified maximum, operational controls shall be used to ensure that the maximum number of occupants is not exceeded.

**A.5.4.5.4** The number of people expected to be contained in a room or area should be based on the occupant load factor specified in [Table 7.3.1.2](#) or other approved sources.

An example of another approved source for occupant load factors is zoning regulations. Also, the authority having jurisdiction might specify a higher occupant load than that calculated using the occupant load factors of [Table 7.3.1.2](#) to provide an additional safety margin.

The occupant characteristics specified for a performance-based design need to provide an accurate representation of the abilities and behaviors of the building occupants before and during a fire. This information is critical to a performance-based design if the design is to be based on and compared with Method 2 of [A.5.2.2](#). The selection of Method 2 requires that each room or area be fully evacuated before the smoke layer in that room descends below 6 ft (1830 mm) above the floor. To show that each space is clear before the smoke layer reaches this level, the designer must document the spread of fire, its products of combustion, and the movement of people throughout the building during the emergency as accurately as possible using current verification methods. To model the evacuation of the building, characteristics of the occupants of that building must be formulated. The overall function of occupant characteristics is the estimation of the time required to evacuate the building. Therefore, the designer also needs to formulate response characteristics, which dictate how the occupants perceive the fire threat, the time required to respond to this threat, and the time to evacuate the building once the decision has been made to leave. Additionally, the designer needs to determine the number and location of people occupying the structure at the time of fire initiation. Staff assistance and emergency response, which also

have an impact on evacuation time, are presented in separate examples in the commentary on this chapter.

### **Example: Response Characteristics, Location, and Number of Occupants**

This example presents a sample of occupant characteristics that could be used as the basis for an egress analysis. It is critical that the designer account for premovement activities when completing an egress analysis, as occupants will often spend as much time, if not far more, deciding and preparing to leave than they actually spend moving through the building.<sup>9</sup> The list of occupant characteristics is based on a hypothetical, three-story apartment building as shown in [Exhibit 5.4](#). This building has two enclosed exit stairs located in proximity to two of the opposite corners of the structure. The stair on the bottom right-hand side of [Exhibit 5.4](#) is assumed to be the main, front stairway for the structure — the egress path most familiar to the majority of the people in the building. The building is laid out such that there are 16 one-bedroom apartments (2–5, 8–11, 13–16, and 18–21) and 6 three-bedroom apartments (1, 6, 7, 12, 17, and 22), as follows:

#### *16 Small Apartments (2–5, 8–11, 13–16, and 18–21)*

Single bedroom

Two people per apartment

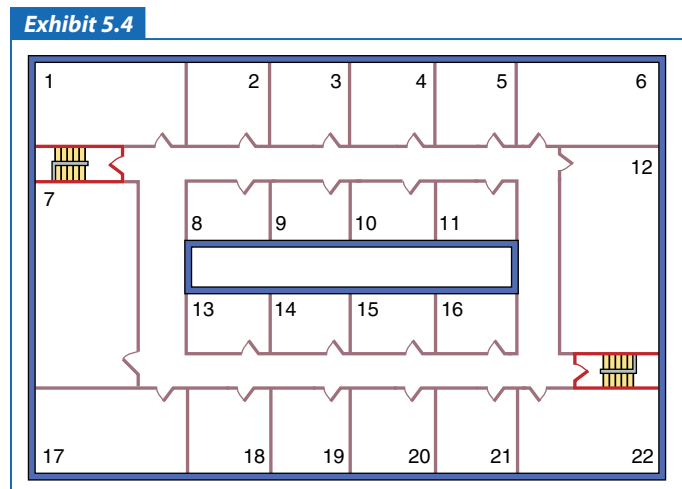

Two mobility-impaired people (walking disabled) per floor; baseline case locations, apartments 3 and 14 — subject to sensitivity analysis

#### *6 Large Apartments (1, 6, 7, 12, 17, and 22)*

Three bedrooms

Three apartments with two adults and two children; three apartments with two adults and three children; baseline case locations, five-person apartments 7, 12, and 17

Distribution of four- and five-person apartments subject to sensitivity analysis

*Three-story apartment building typical floor plan.*

**Notification Time.** Notification time is the time from ignition until the sounding of the alarm. Notification time depends on the fire scene and design specification of the detection and alarm system.

**Reaction Time.** Assume everyone in the building is sleeping at the time of alarm. This state of sensibility presents a delay in the reaction time of the occupants. Additionally, average reaction time is highly influenced by the performance of the detection and alarm system. The average reaction time of adult occupants is determined on the basis of the condition of occupants at the time of alarm (sleeping), the design features and audibility of the alarm system, and any local regulation relating to delay times to be used in egress analysis. This example assumes that children will not react and prepare to evacuate without prompting from adults; therefore, only an estimate for adults is to be provided. The predicted range of reaction time is to be provided.

**Pre-Evacuation Time.** An additional factor that needs to be considered when performing egress analyses is activities that occupants engage in before leaving the building. These activities range from gathering children or pets to getting dressed and packing up valuable belongings. The climate of the building location might factor into the delay time, as occupants are more reluctant to go outside in particularly cold weather, and — before they do — more time will be spent finding and donning jackets and other clothing. In the case of mobility-impaired individuals who require mobility aids, delay time will also include the time required to find, gather, and begin using these devices. An average time for pre-evacuation activities is to be specified for each of the apartment groups. For this example, the apartments housing two adults and no children have pre-evacuation times based on the time required to get dressed; gather items such as a jacket, keys, shoes, and a wallet; and then begin to egress the building. An additional amount of time should be added for those apartments housing mobility-impaired individuals. For those apartments housing children, an additional time factor should be added for the time required to get the children together, dressed, and ready to move out of the building. Information on reaction time and pre-evacuation activities is critical for the completion of an accurate egress analysis. This information can be found in the *NFPA Fire Protection Handbook*, the *SFPE Handbook of Fire Protection Engineering*, or tests, such as those cited in the Proulx and Fahy paper.<sup>10</sup>

In summary, the following pre-evacuation times are also to be included in the egress analysis:

1. Adult apartments pre-evacuation time — provide predicted range based on specific occupant characteristics and available literature and test data
2. Adult apartments for mobility-impaired individuals pre-evacuation time — provide predicted range
3. Apartments with children pre-evacuation time — provide predicted range

**Travel Time.** The final component of an egress analysis is the calculation of the time required for occupants to leave the structure once they begin to evacuate. This travel time is primarily based on the location of the occupants and the speed at which they can navigate through the building. Depending on the structure in question, the occupants' ability to move might be affected by crowding phenomena and unfamiliarity with the structure. Other factors that influence travel time are as follows:

1. Families remain in a group throughout evacuation and move at the speed of the slowest member.
2. Occupants have varied familiarity with the structure.
3. Occupants egress via the most familiar path, unless fire or products of combustion block that path; assume occupants from apartments 1, 2, 3, 7, 8, 9, and 17 attempt to use the stairway in the upper left-hand corner of Exhibit 5.4, while the rest of the occupants use the stairway in the bottom right-hand corner of the exhibit.

Occupant movement speeds are available from several sources, including the *NFPA Fire Protection Handbook*, the *SFPE Handbook of Fire Protection Engineering*, and *Fruin's Pedestrian Planning and Design*,<sup>11</sup> or from tests on different samples of the population.

Movement speeds for the following are to be included in the egress analysis:

1. Adults on floor — provide predicted range based on available literature and test data
2. Adults on stairs — provide predicted range
3. Families with children on floor — provide predicted range
4. Families with children on stairs — provide predicted range
5. Mobility-impaired adults on floor — provide predicted range
6. Mobility-impaired adults on stairs — provide predicted range

Egress time is calculated as follows:

$$\text{Egress time} = t_n + t_r + t_p + t_t$$

where:

- $t_n$  = notification time
- $t_r$  = reaction time
- $t_p$  = pre-evacuation time
- $t_t$  = travel time

**5.4.5.5\* Staff Assistance.** The inclusion of trained employees as part of the fire safety system shall be identified and documented.

**A.5.4.5.5** For example, in hospitals, staff characteristics such as number, location, quality, and frequency of training should be considered.

Certain occupancies or building types might require that staff assistance be provided during the evacuation procedure in order for the occupants to evacuate the building safely. The assistance

of trained staff in public places, such as department stores, shopping malls, theaters, arenas, or similar buildings, can help occupants unfamiliar with the building find emergency exits, accelerating their departure and reducing the overall evacuation time. However, it is important that staff members who are accounted for in a design be properly trained and drilled so that they are familiar with their role in the evacuation of the building.

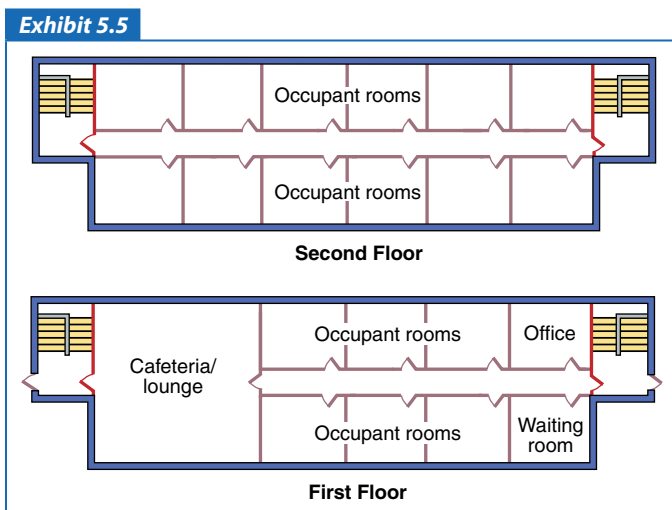

Other examples of occupancies where staff assistance might be required are nursing homes, hospitals, and residential board and care facilities. In facilities housing the elderly or mentally or physically impaired individuals, occupants might be slow to react to warning or alarm systems and might be slow in moving as well. Depending on the severity of the impairment of the occupants, evacuation time might be extremely prolonged without the incorporation of staff assistance. Take, for example, a nursing home that houses nonambulatory occupants incapable of self-preservation. The range of impairments of the occupants might include the following:

1. Inability to hear an alarm
2. Inability to comprehend the significance of an alarm
3. Inability to walk unassisted
4. Inability to move at all without the use of a wheelchair

Due to the varied nature of the occupants in such a setting, the designer will most likely be unable to predict the types of impairments that the occupants of that building will have at any specific time.

### Example: Staff Assistance

The hypothetical building for this example is a two-story nursing home with 6 occupant rooms, an entrance/waiting room, a desk/office area, and a cafeteria/lounge on the first floor; and 12 occupant rooms on the second floor. Exhibit 5.5 shows a plan view for each floor.

Two-story nursing home.

There are a total of 18 rooms, each housing 2 patients, for a total permanent occupancy of 36 patients. These people might suffer from a variety of impairments, which will greatly affect their ability to egress the building in a timely manner in the event of an emergency. This example assumes that any occupant confined to a wheelchair is housed on the ground floor. The occupant characteristics for this building are not discussed in detail for this example, as occupant characteristics and their impact were addressed in the commentary to A.5.4.5.4. However, this example briefly presents the impact of staff assistance on the various time components that can be used to determine the total egress time.

It is assumed that the occupants of the building are sleeping. Because there is a fairly high likelihood that some of the occupants of this building are hearing impaired or might be unable to comprehend and react to an alarm, the reaction time for this component of the population could be infinite. Additionally, elderly occupants might take more time getting dressed and preparing to leave, further lengthening the pre-evacuation time. There is a high likelihood that some of the occupants of this structure suffer from mobility or mental impairments, which would also affect their travel time. Some of the occupants might be unable to move without assistance, so their travel time will be infinite, while others might simply move at a very slow pace.

Staff assistance can be factored into a design to negate some of the effects of various impairments on egress time. The actual level of staff required in a structure of this type might be restricted by local jurisdictions and individual company specifications. For this example, it is assumed that the building is staffed full-time with three nurses, seven aides, and a desk clerk. Two of the nurses and four of the aides are located on the second floor. The designer should work with the building owner and stakeholders to develop a written facility fire safety plan that outlines each person's responsibility in the event of a fire. For this example, it is assumed that, upon alarm and confirmation of a fire, the desk clerk is to notify and interact with the fire department, while the nurses and aides help the occupants to evacuate the building.

The designer must make certain assumptions regarding the facility staff and the degree to which they will affect the occupant response characteristics and evacuation. There must be a basis for each assumption made by the designer regarding staff assistance, and each should be documented. Assumptions might include the following:

1. All patients are under 24-hour supervision and their location is always known.
2. Wheelchair-bound patients are located on the first floor only, and the occupants either are seated in, or located near, their wheelchairs.
3. The facility has an emergency evacuation plan that is practiced twice a year.
4. Each nurse and aide is assigned a patient or group of patients who they must ensure escapes safely from the building.

5. Upon hearing an alarm, the staff verifies that there is a fire, notifies each of the occupants, and proceeds to take the following actions:
  - a. The staff closes the door to each room upon leaving to prevent smoke from entering that room.
  - b. The staff begins helping those in need of assistance in moving through the building.

The effects of staff assistance on the time to evacuation can be stated with each component of the egress analysis time, based on the assumptions made. The first component of the egress time calculation is the time to notification. This component is generally based on the sounding of the alarm, but one of the assumptions for this example is that the staff verifies the existence of a fire before helping to notify the occupants. This action introduces a time delay in the notification time. The second and third components of the egress time calculation are the reaction and pre-evacuation times. As previously discussed, these times might be dramatically affected by hearing, mental, or physical impairments. When the staff is notifying the occupants of the fire, they need to ensure that each occupant capable of evacuating without assistance begins to react, or staff is to help them to begin evacuating the structure. This might include getting each occupant dressed and prepared to leave, as well as placing the occupants into wheelchairs, if necessary.

The delay estimate for staff assistance must include consideration of the fact that each member of the staff might be responsible for more than one person and that there might be delays associated with each person. For the example presented here, the average staff member is assigned three or four people, and an average delay developed depends on the anticipated level of impairment associated with each person. These actions introduce further delays in the reaction and pre-evacuation activities.

Finally, the staff aids the occupants in moving through the building. This might include wheeling them out of the building, walking next to them throughout the egress process, or simply directing them out of the building. Initially, estimates are to be made for each of these delays, and these estimates are to be confirmed by the evacuation drills.

**5.4.6 Emergency Response Personnel.** Design characteristics or other conditions related to the availability, speed of response, effectiveness, roles, and other characteristics of emergency response personnel shall be specified, estimated, or characterized sufficiently for evaluation of the design.

Depending on the design in question, it might be desirable to omit the operations of emergency response personnel. If this is the case, this assumption is to be documented as part of the final design.

Depending on the type of occupancy and the use of the building, the designer might wish to incorporate the actions of emergency personnel into the evaluation of the structure. The design team needs to make many assumptions regarding the

time to arrival and overall capabilities of the response personnel, and these assumptions must be incorporated into the design documentation. The designer cannot simply assume that the fire department will arrive 30 seconds after the initial fire alarm and suppress the fire immediately upon arrival. The example that follows is provided to present the type of questions that should be addressed regarding emergency response personnel, as well as some of the assumptions that might be made.

#### **Example: Emergency Response Personnel**

The facility in this example is an industrial occupancy located on the outskirts of a suburban town. The facility manufactures plastic products and runs two shifts per day. There are two buildings on the campus. One building houses the administrative personnel and design team offices as well as a cafeteria and lounge; all of the manufacturing takes place in the other building. The processes used in manufacturing the product are hazardous and involve the use of toxic and flammable chemicals. The town has two full-time fire stations, both with the same resources. One is located 5 mi (8 km) from the facility; the other is 10 mi (16 km) from the facility.

When determining the assumptions that can be made about the emergency response personnel, it might be useful for the designer to develop a list of questions to ask the owner and authority having jurisdiction or fire department representative on the design team. The answers to such questions can help assess the level of dependence the design should have on the arrival of the fire department. The following are sample questions:

1. Is there a fire brigade on-site?
2. What is the brigade's level of training?
3. What is the estimated response time of the local fire department?
4. How many response personnel will respond with the first arriving company?
5. How many response personnel will respond with the second arriving company?
6. Is the local fire department familiar with, and trained to respond to, emergencies at the facility?
7. When an alarm is sounded, does the signal go straight to the local fire department or to a security station on-site?
8. Who will assess the situation before calling the local fire department?
9. What types of hazards exist on-site, and where are they located?
10. Do these hazards pose health threats to the surrounding community, to the employees, or to the fire fighters?
11. Does the local fire department have the equipment to respond to the types of fire incidents that could develop?
12. Does the municipality or the plant supply the equipment specified in item 11?
13. If supplied by the company, is the equipment stored on-site?

14. What type of access to the site is used by the fire department?
15. How long will it take fire fighters to set up for suppression efforts at a range of locations on the campus?

All assumptions regarding the fire department's response time need to be verified as feasible by the fire department. The overall intention of these questions regarding the fire department and its capabilities is to determine the time to arrival, the time to agent application, and the time to suppression, which can then be incorporated into the building evaluation. These various times should take into consideration not only the fire department but also the building, as the designer should be aware that certain building designs present more challenging situations than others. When emergency response personnel are to be an important part of the fire safety design, the designer needs to try to make the building as friendly to the fire department as possible. To facilitate this process, the designer should consult with the fire department early in, and throughout, the process to ensure that the design is optimized for fire-fighting operations and that any assumptions made regarding the fire department are accurate.

**5.4.7\* Post-Construction Conditions.** Design characteristics or other conditions related to activities during the life of a building that affect the ability of the building to meet the stated goals and objectives shall be specified, estimated, or characterized sufficiently for evaluation of the design.

**A.5.4.7** Design proposals need to state explicitly any design specifications or estimations regarding building fire safety plans, inspection programs, or other ongoing programs whose performance is necessary for the building, when occupied and operational, to meet the stated goals and objectives. Programs of interest include any maintenance, training, labeling, or certification programs required to ensure operational status or reliability in building systems or features.

**Subsection 5.4.7** relates to the management-of-change issues discussed in 5.1.7. One design characteristic that typically changes post-construction is the fuel load. The design basis fuel load must anticipate such changes, no matter what their size. Increased quantities of fuel load involving materials that are easier to ignite and involving higher and faster growing heat release rates, with higher smoke generation rates, could have a significant impact on the performance-based design. Neither the designer nor the authority having jurisdiction will want to reanalyze the design's acceptability fully whenever post-construction conditions change slightly. To avoid that need while maintaining safety, the designer must use assumptions that are more conservative than the conditions actually anticipate and also identify those conditions of greatest sensitivity that must be maintained or reanalyzed.

**5.4.8 Off-Site Conditions.** Design characteristics or other conditions related to resources or conditions outside the property

being designed that affect the ability of the building to meet the stated goals and objectives shall be specified, estimated, or characterized sufficiently for evaluation of the design.

Off-site conditions are considered to be outside the property line and out of the control of the owner/operator. One example of an off-site condition is the status of the public water main. If the fire protection design relies on a sprinkler system fed by the public water main, then the analysis should consider the possibility that the public water main won't deliver the required amount of water.

**5.4.9\* Consistency of Assumptions.** The design shall not include mutually inconsistent assumptions, specifications, or statements of conditions.

**A.5.4.9** The design elements required to be excluded by 5.4.9 include those regarding the interrelations between the performance of building elements and systems, occupant behavior, or emergency response actions that conflict with each other. For each fire scenario, care needs to be taken to ensure that conflicts in actions do not occur. Typical conflicts could include the following:

- (1) Assuming a fire door will remain closed during the fire to contain smoke while this same door is used by occupants during egress from the area
- (2) Assuming fire apparatus will arrive immediately from a distant location to provide water to fire department connections and similar situations

For example, an assumption that compartmentation blocking the passage of fire and smoke will be maintained at the door to a stairwell cannot be paired with an assumption that evacuation through that door will extend over many minutes.

**5.4.10\* Special Provisions.** Additional provisions that are not covered by the design specifications, conditions, estimations, and assumptions provided in Section 5.4, but that are required for the design to comply with the performance objectives, shall be documented.

**A.5.4.10** The provisions required by 5.4.10 to be documented include those that are in excess of basic requirements covered by referenced codes and standards, typical design requirements, and operating procedures. Such provisions include the following:

- (1) More frequent periodic testing and maintenance to increase the reliability of fire protection systems
- (2) Redundant systems to increase reliability
- (3) On-site guard service to enhance detection of fires and aid in fire response procedures
- (4) Staff training
- (5) Availability and performance of emergency response personnel
- (6) Other factors

## 5.5\* Design Fire Scenarios

**A.5.5** Design fire scenarios define the challenge a building is expected to withstand. Design fire scenarios capture and limit value judgments on the type and severity of the fire challenge to which a proposed fire safety system needs to respond. The system includes any and all aspects of the proposed design that are intended to mitigate the effects of a fire, such as egress system, automatic detection and suppression, barriers, staff training, and placement of manual extinguishers.

Design fire scenarios come from two sources: those that are specified in 5.5.3.1 through 5.5.3.8, and those that are developed by the design team based on the unique characteristics of the building as required by 5.5.2. In most, if not all, cases, more than one design fire scenario will be developed to meet the requirements of 5.5.2.

Once the set of design fire scenarios is established, both those specified by 5.5.3.1 through 5.5.3.8 and those that are developed as required by 5.5.2, they need to be quantified into a format that can be used for the evaluation of proposed designs. The *SFPE Engineering Guide to Performance-Based Fire Protection* outlines a process and identifies tools and references that can be used at each step of this process.

**5.5.1 Approval of Parameters.** The authority having jurisdiction shall approve the parameters involved in design fire scenarios. The proposed design shall be considered to meet the goals and objectives if it achieves the performance criteria for each required design fire scenario. (See 5.5.3.)

**5.5.2\* Evaluation.** Design fire scenarios shall be evaluated using a method acceptable to the authority having jurisdiction and appropriate for the conditions. Each design fire scenario shall be as challenging as any that could occur in the building, but shall be realistic, with respect to at least one of the following scenario specifications:

- (1) Initial fire location
- (2) Early rate of growth in fire severity
- (3) Smoke generation

**A.5.5.2** The protection systems and features used to meet the challenge of the design fire scenario should be typical of, and consistent with, those used for other similar areas of the building. They should not be designed to be more effective in the building area addressed than in similar areas not included and that are, therefore, not explicitly evaluated.

**Paragraph A.5.5** indicates that 5.5.2 will typically force one or more scenarios to be considered in addition to the eight specified in 5.5.3.1 through 5.5.3.8. The specified scenarios are to be considered for all performance-based designs, but they do not necessarily represent a comprehensive set of scenarios. There might be additional scenarios truly unique to the proposed facility that need to be analyzed. The intent of including nonspecific

scenarios (as opposed to the specific scenarios of 5.5.3) is to capture those scenarios in which initial fire location, early rate of growth in fire severity, or smoke generation (see 5.5.2) poses a greater problem than those conditions captured by the scenarios in 5.5.3. However, there are also other conditions that may require development of scenarios — the overcrowding of a specific space being just one example. The authority having jurisdiction might also specify additional scenarios to account for a historical, local fire that the AHJ is determined will not recur.

The discussion that follows suggests how suitable scenarios may be developed.

### Introduction

To provide a comprehensive design (i.e., to demonstrate how the fire safety system will respond to a variety of fires), more than one scenario should be considered. It is suggested that, at a minimum, the following three types of scenarios be considered:

1. High-frequency, low-consequence scenario (typical)
2. Low-frequency, high-consequence scenario (high-challenge)
3. Special problems scenario

The scenario in item 1 is used to demonstrate that the fire safety system can manage fires that start as relatively small fires but are frequent (e.g., a wastebasket fire). The scenario in item 2 should present a greater challenge to the fire safety system (e.g., fire in an egress path). The intent is to consider a larger fire, but not one that is so unrealistically large that it ensures the proposed design (or any other) will not perform adequately. The first two scenario types tacitly assume that the fire safety system will function as designed. However, the scenario in item 3 is included to account for those situations in which some aspect of the fire safety system might be compromised (e.g., improperly closed valve on a sprinkler system, detection/alarm system temporarily out of service, degradation of egress system after an earthquake or other natural disaster). The scenario in item 3 can also be used to consider the reliability of the fire safety system design.

**Commentary Table 5.1** provides general scenarios — those that may be experienced by most, if not all, occupancies. **Commentary Table 5.1** presents examples of typical and high-challenge fires, based on slow-, moderate-, and fast-developing fires that expose people in the room of origin who are not intimate with ignition, and based on when the room of origin is unoccupied. The table also presents examples of special problem fires for these same individuals.

The left column of **Commentary Table 5.1** indicates a general fire type, characterized by the rate at which a potential fire hazard might develop. Fire development is defined by a heat release rate curve (HRRC). An additional factor in defining the type of fire is the peak heat release rate, which must be severe enough to challenge the fire safety system but not so severe that no design can effectively reduce the hazards of the postulated fires. The peak heat release rate is a function of the amount of

**Commentary Table 5.1 General Scenarios**

Fire Type	Scenario	
	Occupant in Room of Fire Origin but Not Intimate	Room of Fire Origin Normally Unoccupied
Slow-developing fire	<ul style="list-style-type: none"> <li>• Cigarette ignition of upholstered furniture</li> <li>• Electrical ignition of small appliance or lighting, or overloaded outlet</li> </ul>	<ul style="list-style-type: none"> <li>• Overloaded or failed wiring igniting switch gear, electrical devices, or insulation, followed by ignition of wooden structural members</li> </ul>
Moderate-developing fire	<ul style="list-style-type: none"> <li>• Kitchen/cooking fire</li> <li>• Trash can fire</li> <li>• Open flame ignition of upholstered furniture</li> </ul>	<ul style="list-style-type: none"> <li>• Wildland or exposure fire (e.g., from a neighboring building or parked car)</li> <li>• Lightning-induced ignition of building roof</li> <li>• Laundry room fire</li> </ul>
Fast-developing fire	<ul style="list-style-type: none"> <li>• Flammable liquids</li> </ul>	<ul style="list-style-type: none"> <li>• Flammable liquid storage</li> </ul>
Shielded from systems, or other problems present	<ul style="list-style-type: none"> <li>• Fire with impaired “first line of defense”</li> <li>• Shielded flaming fires; limited fuel and larger</li> </ul>	<ul style="list-style-type: none"> <li>• External trash collection or trash chute fire</li> <li>• Flammable liquid storage</li> <li>• Room of fire origin door open</li> <li>• Fire in egress path</li> </ul>

fuel of the first item ignited, if the fire doesn't spread beyond that first item, or the maximum amount of fuel within the room of origin (e.g., the room goes to flashover).

### Scenario Components

At a minimum, a fire scenario consists of the following:

1. Ignition factors (source, location, and material; other items ignited, if applicable)
2. At least one heat release rate curve (HRRC)
3. Occupant locations (see 5.4.5.3)
4. Occupant characteristics (see 5.4.5.2)
5. Special factors (shielded, systems unreliable, open door)

**Ignition Factors.** Ignition factors include the source of ignition; the material that is first ignited and, if it is a solid, where it is ignited; and whether other items are also ignited. Ignition factors to consider when constructing a fire scenario are shown in [Commentary Table 5.2](#).

**Ignition Source.** Ignition sources are of primary interest when considering the frequency of design fires. Possible sources of ignition include the following:

1. Smoking
2. Open flame
3. Electrical source
4. Incendiary
5. Hot surface
6. Spontaneous combustion
7. Radiant source

Various electrical ignition scenarios are possible, and historical data should be consulted to determine which is most appropriate for the occupancy being considered. In addition to smoking-related ignitions and open flames, another example of

incendiary ignition would be a “runaway” industrial reaction. Hot surfaces are most often associated with either cooking (stoves, hot plates) or industrial processes (engines, furnaces). Spontaneous combustion is essentially an uncontrolled exothermic chemical reaction, due to either a buildup of flammable vapors (e.g., due to improper storage or decomposition) or accidental mixing of reactive chemicals (e.g., some cleaning fluids). A common radiant source is a portable heater.

*First Item Ignited.* The first item ignited is somewhat dependent on the ignition source. For example, an overheated electrical wire is most likely to ignite its own insulation; cooking fires usually ignite items close to the flames, not structural assemblies (e.g., wall or ceiling finish materials). The first item ignited is of interest for two reasons. First, it may pose either a thermal or a nonthermal hazard by itself (e.g., an occupied mattress or the toxic products resulting from its combustion). Second, the first item might ignite a second item that poses an additional or greater hazard. Examples of second items include merchandise, structural assemblies, and carpets capable of releasing toxic combustion products. There may be no need to consider the “second item ignited” column of [Commentary Table 5.2](#) if the first item ignited presents enough of a hazard by itself. Certain types of upholstered furniture fall into this category because of the toxic combustion products they release and their relatively high heat release rate.

*Second Item Ignited.* Ignition of a second item is important in scenarios involving flashover or where structural stability is an issue. Ignition of a second item should be reflected in the heat release rate curve for the room of origin. Ignition of a second item can have the following two effects on the room heat release rate curve:

1. The peak heat release rate might be increased.
2. The growth phase of the fire might be accelerated.

**Commentary Table 5.2 Ignition Factors**

<i>Ignition Source</i>	<i>First Item Ignited</i>	<i>Second Item Ignited</i>
Cigarette	Electrical equipment <sup>1</sup>	Structural assembly <sup>2</sup>
Electrical lighting	Wiring	Library book stack
Incendiary	Seating	Merchandise display
Spontaneous combustion	Sets and decorations	Carpets
Stove/hot plate	Exhibit displays	Curtains
Process-inherent source or item <sup>3</sup>	Upholstered furniture	
	Electrical appliance	
	Trash	
	Ordinary combustibles <sup>4</sup>	
	Gas leaks	
	Flammable liquids	
	Mattress	
	Medical equipment	

<sup>1</sup>Includes, but is not limited to, dust collectors, uninterruptible power supplies, generators, HVAC equipment, dryers, and freezers

<sup>2</sup>Consists of exterior/interior wall or ceiling finish, wall studs, ceiling joists, and insulation

<sup>3</sup>Applies primarily to industrial settings

<sup>4</sup>Includes mixtures of paper, common plastics, and other materials

The possibility of both phenomena occurring might apply to certain scenarios (e.g., if the second item involves flammable liquids or gases).

**Heat Release Rate Curves.** Heat release rate curves can be constructed by referring to the *SFPE Handbook of Fire Protection Engineering* and Drysdale's *An Introduction to Fire Dynamics*.

**Special Factors.** The additional factors that follow might be critical to the development of scenarios.

*Ignition Location.* The location of the point of ignition can affect the eventual course and spread of a fire. In some cases, specifying a location also implies additional items in the scenario. For example, a kitchen fire could actually be a cooking fire that involves a burner igniting loose clothing or a grease fire igniting "ordinary" combustibles nearby.

*Fire Spread.* With regard to fire spread, the point of ignition is significant because it might, in part, determine the severity of the fire. An aspect of this issue is the availability of oxygen. If the first item ignited is an upholstered chair, two different scenarios result, depending on whether the ignition location is on the outside (e.g., ignition by a wastebasket fire) or on the inside (e.g., ignition by a cigarette between a seat cushion and the arm of the chair). In the former case, a flaming fire is likely to occur; in the latter, a smoldering fire with copious amounts of products of combustion results. Additionally, the point of origin might be conducive to localized flashover. Localized flashover has been observed in experiments involving bunk beds and desks with enclosed leg wells (modesty panels). These geometries tend to concentrate heat energy such that an intense fire is created in a relatively small area.

*Relative Location.* Relative location is somewhat related to the localized flashover. These fires are characterized by the ignition

point being shielded from fire protection systems. The problem is that the initial fire development is not sensed by the fire detection system. This results in a larger fire at the time of detection and a commensurate decrease in the time to evacuate. A common scenario involving shielded fires is a fire in warehouse rack storage.

*Interference with Evacuation.* The loss or degradation of any one egress path (e.g., when a fire originates in some aspect of the egress system) can place a significant burden on the fire safety system of a facility. If more than two exits exist, the loss of one will have a lesser impact than if only one or two exits are initially available. If a fire originates in a location shared by more than one egress path (e.g., where two egress paths merge into a single corridor or a dead-end corridor), the impact is greater than if the fire originates in one of several parallel egress routes.

*Compartmentation Barriers.* This situation involves the fire breaching a barrier or originating in a concealed space or on an exterior surface. When the fire breaches a barrier, the potential for a severe fire increases. The problem with fire originating in a concealed space or on an exterior surface is similar to that addressed under the factor "relative location" (fire shielded from detection or suppression systems).

## General Design Scenarios

The general design scenarios shown in [Commentary Table 5.3](#) are recommended as a starting point, since they encompass the issues addressed in earlier commentary. For those instances in which [Commentary Table 5.3](#) does not apply, a process is provided for selecting components for site-specific scenarios that address the concepts of these general scenarios.

**Commentary Table 5.3 General Design Scenarios**

<i>Typical Scenario</i>	<i>High-Challenge Scenario</i>	<i>Special Problem Scenario</i>
Fast growth in room contents	Flammable liquids in means of egress	Ordinary fire in typical unoccupied room with sprinklers or detectors out of commission
Ordinary fire in attic or “challenging” concealed space	Largest room fire, fastest growth consistent with use; worst occupant characteristics	
Ordinary fire in typical occupied room with people not intimate with ignition		
Slow-developing fire in typical occupied room with worst-case occupant characteristics	Worst flame spread fire, if area critical to egress; or flammable room linings or decorations	

## Development of Scenarios

The guidelines that follow are for use in specifying fire scenarios.

### Typical Scenarios

Typical scenarios can be specified partly through routine statistical analysis of fire experience in similar buildings. An advantage of common or typical scenarios is that they provide a good prediction of the building’s performance if fire occurs. Such scenarios also tend to fit easily within the scope of available fire models and calculation methods. This means the authority having jurisdiction can review the results for these scenarios to obtain a basic sense of the building’s level of safety and the appropriateness of the calculations.

### High-Challenge Scenarios

High-challenge scenarios are any scenarios that pose unusual fire challenges to the building design. High-challenge scenarios can be developed by refining common scenarios (e.g., changing the area of fire origin) to create a greater challenge. Also, high-challenge scenarios can be developed by reducing the challenge in scenarios previously identified as beyond the design expectations (i.e., too severe to use as the basis for evaluation).

The illustrative techniques that follow are to be used for developing high-challenge scenarios from typical scenarios.

**1. Change the area of fire origin.** Consider an area (e.g., a bedroom) where occupants are likely to be particularly vulnerable. Consider an area (e.g., a concealed space, an external surface) where fire can develop outside the effective range of key fire protection features (such as detectors or sprinklers). Consider an area (e.g., an egress corridor) that is critical to occupant movement to safety.

**2. Increase the initial size or speed of the development of the fire.** This might be done by adjusting the parameters in a fire growth model (e.g., increasing the alpha value in a *t*-squared modeled fire; creating a scenario that reflects a fast or ultrafast fire; increasing the peak heat release rate value for the fire) or by increasing the assumed room fuel load or decreasing the space between major combustible items.

**3. Assume common degradations in design assumptions.** For example, assume the doors are blocked open, allowing the passage of fire effects to secondary spaces; or assume an unlimited oxygen supply for fire growth that could result from open doors, broken windows, or other circumstances.

**4. Increase the toxicity or yields of products of combustion.**

Developing high-challenge scenarios from scenarios beyond design expectations involves less-challenging quantitative assumptions. For example, if the bomb used in the New York City World Trade Center incident of 1993 were to be deemed too severe for a high-rise office building, how small a bomb would constitute an appropriate high-challenge test? To pose another example, if the *Code* cannot ensure protection of occupants who are intimate with initial fire development, how close can occupants be without being considered intimate?

**5.5.3\* Required Design Fire Scenarios.** Design fire scenarios shall comply with the following:

- (1) Scenarios selected as design fire scenarios shall include, but shall not be limited to, those specified in 5.5.3.1 through 5.5.3.8.
- (2) Design fire scenarios demonstrated by the design team to the satisfaction of the authority having jurisdiction as inappropriate for the building use and conditions shall not be required to be evaluated fully.

**A.5.5.3** It is desirable to consider a wide variety of different fire scenarios to evaluate the complete life safety capabilities of the building or structure. Fire scenarios should not be limited to a single or a couple of worst-case fire scenarios.

The descriptive terms used to indicate the rate of fire growth for the scenarios are intended to be generic. Use of *t*-squared fires is not required for any scenario.

One or more of the required eight design fire scenarios specified in 5.5.3.1 through 5.5.3.8 might not apply. For instance, if the designer is analyzing a building that serves primarily as a warehouse but also has limited office space, and that building does not have any concealed wall or ceiling spaces, then Design Fire Scenario 4 (see 5.5.3.4) might not be applicable.

Another example of a situation in which one of the required scenarios might not apply to a particular design is a building isolated from any possible exposure to outside fire sources, which eliminates the need to evaluate the building using Design Fire Scenario 7 (see 5.5.3.7). The possible ignition or fuel sources for an exposure fire might include trees or vegetation, cars, delivery trucks, or dumpsters. If the designer can show the authority having jurisdiction that the building is designed such that there would be no vegetation around the perimeter; that no personnel or delivery vehicles could park next to, or even within, a certain distance of the building; and that no man-made flammable objects would be placed around the perimeter of the building, then this scenario might not be applicable.

Each of the theoretical examples would be very rare, and justifying the inappropriateness of any of the scenarios could be very difficult for the designer. The majority of buildings to which one or more of the required scenarios do not apply will generally be very specialized cases, such as an aircraft hangar with no concealed spaces or a research lab with no external fuel sources that could lead to an exposure fire. If the designer believes that one or more of the scenarios do not apply to the building in question, the designer should consult the authority having jurisdiction early in the evaluation process and provide written justification for why the scenarios do not apply.

**5.5.3.1\* Design Fire Scenario 1.** Design Fire Scenario 1 shall be described as follows:

- (1) It is an occupancy-specific fire representative of a typical fire for the occupancy.
- (2) It explicitly accounts for the following:
  - (a) Occupant activities
  - (b) Number and location of occupants
  - (c) Room size
  - (d) Contents and furnishings
  - (e) Fuel properties and ignition sources
  - (f) Ventilation conditions
  - (g) Identification of the first item ignited and its location

**A.5.5.3.1** An example of Design Fire Scenario 1 for a health care occupancy would involve a patient room with two occupied beds with a fire initially involving one bed and the room door open. This is a cursory example in that much of the explicitly required information indicated in 5.5.3.1 can be determined from the information provided in the example. Note that it is usually necessary to consider more than one scenario to capture the features and conditions typical of an occupancy.

The idea behind Design Fire Scenario 1 is to ensure that the types of fires most likely to occur in a given occupancy type — that is, the statistically most significant scenarios — are considered in the design analysis. These scenarios have a great degree of variety, from the small fires experienced weekly at aluminum rolling mills to the kitchen fires in high-rise apartment buildings (i.e., residences).

**5.5.3.2\* Design Fire Scenario 2.** Design Fire Scenario 2 shall be described as follows:

- (1) It is an ultrafast-developing fire, in the primary means of egress, with interior doors open at the start of the fire.
- (2) It addresses the concern regarding a reduction in the number of available means of egress.

**A.5.5.3.2** Design Fire Scenario 2 examples include a fire involving ignition of gasoline as an accelerant in a means of egress, clothing racks in corridors, renovation materials, or other fuel configurations that can cause an ultrafast fire. The means of egress chosen is the doorway with the largest egress capacity among doorways normally used in the ordinary operation of the building. The baseline occupant characteristics for the property are assumed. At ignition, doors are assumed to be open throughout the building.

Design Fire Scenario 2 is intended to provide information on the maximum potential spread of fire effects, mostly smoke and toxic products. It answers the question “What is the maximum extent of smoke that may be experienced if an egress path is blocked?”

**5.5.3.3\* Design Fire Scenario 3.** Design Fire Scenario 3 shall be described as follows:

- (1) It is a fire that starts in a normally unoccupied room, potentially endangering a large number of occupants in a large room or other area.
- (2) It addresses the concern regarding a fire starting in a normally unoccupied room and migrating into the space that potentially holds the greatest number of occupants in the building.

**A.5.5.3.3** An example of Design Fire Scenario 3 is a fire in a storage room adjacent to the largest occupiable room in the building. The contents of the room of fire origin are specified to provide the largest fuel load and the most rapid growth in fire severity consistent with the normal use of the room. The adjacent occupiable room is assumed to be filled to capacity with occupants. Occupants are assumed to be somewhat impaired in whatever form is most consistent with the intended use of the building. At ignition, doors from both rooms are assumed to be open. Depending on the design, doorways connect the two rooms or they connect via a common hallway or corridor.

For purposes of this scenario, an occupiable room is a room that might contain people; that is, a location within a building where people are typically found.

**5.5.3.4\* Design Fire Scenario 4.** Design Fire Scenario 4 shall be described as follows:

- (1) It is a fire that originates in a concealed wall or ceiling space adjacent to a large occupied room.

- (2) It addresses the concern regarding a fire originating in a concealed space that does not have either a detection system or a suppression system and then spreading into the room within the building that potentially holds the greatest number of occupants.

**A.5.5.3.4** An example of Design Fire Scenario 4 is a fire originating in a concealed wall or ceiling space adjacent to a large, occupied function room. Ignition involves concealed combustibles, including wire or cable insulation and thermal or acoustical insulation. The adjacent function room is assumed to be occupied to capacity. The baseline occupant characteristics for the property are assumed. At ignition, doors are assumed to be open throughout the building.

**5.5.3.5\* Design Fire Scenario 5.** Design Fire Scenario 5 shall be described as follows:

- (1) It is a slowly developing fire, shielded from fire protection systems, in close proximity to a high occupancy area.
- (2) It addresses the concern regarding a relatively small ignition source causing a significant fire.

**A.5.5.3.5** An example of Design Fire Scenario 5 is a cigarette fire in a trash can. The trash can is close enough to room contents to ignite more substantial fuel sources but is not close enough to any occupant to create an intimate-with-ignition situation. If the intended use of the property involves the potential for some occupants to be incapable of movement at any time, the room of origin is chosen as the type of room likely to have such occupants, filled to capacity with occupants in that condition. If the intended use of the property does not involve the potential for some occupants to be incapable of movement, the room of origin is chosen to be an assembly or function area characteristic of the use of the property, and the trash can is placed so that it is shielded by furniture from suppression systems. At ignition, doors are assumed to be open throughout the building.

**5.5.3.6\* Design Fire Scenario 6.** Design Fire Scenario 6 shall be described as follows:

- (1) It is the most severe fire resulting from the largest possible fuel load characteristic of the normal operation of the building.
- (2) It addresses the concern regarding a rapidly developing fire with occupants present.

**A.5.5.3.6** An example of Design Fire Scenario 6 is a fire originating in the largest fuel load of combustibles possible in normal operation in a function or assembly room, or in a process/manufacturing area, characteristic of the normal operation of the property. The configuration, type, and geometry of the combustibles are chosen so as to produce the most rapid and severe fire growth or smoke generation consistent with the normal operation of the property. The baseline occupant characteristics for the property are assumed. At ignition, doors are assumed to be closed throughout the building.

This scenario includes everything from a big couch fire in a small dwelling to a rack fire in combustible liquids stock in a big box retail store.

The Dupont Plaza Hotel fire of 1986 in San Juan, Puerto Rico,<sup>12</sup> is an example of Design Fire Scenario 6. The storage of chairs was part of the normal operating procedures of the hotel. The location and potential heat release of the chairs were evidently considered a small threat due to the lack of an ignition source. Unfortunately, a source was supplied, with tragic results.

**5.5.3.7\* Design Fire Scenario 7.** Design Fire Scenario 7 shall be described as follows:

- (1) It is an outside exposure fire.
- (2) It addresses the concern regarding a fire starting at a location remote from the area of concern and either spreading into the area, blocking escape from the area, or developing untenable conditions within the area.

**A.5.5.3.7** An example of Design Fire Scenario 7 is an exposure fire. The initiating fire is the closest and most severe fire possible consistent with the placement and type of adjacent properties and the placement of plants and combustible adornments on the property. The baseline occupant characteristics for the property are assumed.

This category includes wildlands/urban interface fires and exterior wood shingle problems, where applicable.

**5.5.3.8\* Design Fire Scenario 8.** Design Fire Scenario 8 shall be described as follows:

- (1) It is a fire originating in ordinary combustibles in a room or area with each passive or active fire protection system independently rendered ineffective.
- (2) It addresses concerns regarding the unreliability or unavailability of each fire protection system or fire protection feature, considered individually.
- (3)\* It is not required to be applied to fire protection systems for which both the level of reliability and the design performance in the absence of the system are acceptable to the authority having jurisdiction.

**A.5.5.3.8** Design Fire Scenario 8 addresses a set of conditions with a typical fire originating in the building with any one passive or active fire protection system or feature being ineffective. Examples include unprotected openings between floors or between fire walls or fire barrier walls, failure of rated fire doors to close automatically, shutoff of sprinkler system water supply, nonoperative fire alarm system, inoperable smoke management system, or automatic smoke dampers blocked open. This scenario should represent a reasonable challenge to the other building features provided by the design and presumed to be available.

The concept of a fire originating in ordinary combustibles is intentionally selected for this scenario. This fire, although presenting a realistic challenge to the building and the associated building systems, does not represent the worst-case scenario or

the most challenging fire for the building. Examples include the following:

- (1) Fire originating in ordinary combustibles in the corridor of a patient wing of a hospital under the following conditions:
  - (a) Staff is assumed not to close any patient room doors upon detection of fire.
  - (b) The baseline occupant characteristics for the property are assumed, and the patient rooms off the corridor are assumed to be filled to capacity.
  - (c) At ignition, doors to patient rooms are not equipped with self-closing devices and are assumed to be open throughout the smoke compartment.
- (2) Fire originating in ordinary combustibles in a large assembly room or area in the interior of the building under the following conditions:
  - (a) The automatic suppression systems are assumed to be out of operation.
  - (b) The baseline occupant characteristics for the property are assumed, and the room of origin is assumed to be filled to capacity.
  - (c) At ignition, doors are assumed to be closed throughout the building.
- (3) Fire originating in ordinary combustibles in an unoccupied small function room adjacent to a large assembly room or area in the interior of the building under the following conditions:
  - (a) The automatic detection systems are assumed to be out of operation.
  - (b) The baseline occupant characteristics for the property are assumed, the room of origin is assumed to be unoccupied, and the assembly room is assumed to be filled to capacity.
  - (c) At ignition, doors are assumed to be closed throughout the building.

Design Fire Scenario 8 provides information to the authority having jurisdiction by answering a series of “What if . . . ?” questions. For example, what if the hotel sprinkler system is out of service when a fire occurs? What might be the extent of the fire and smoke and their subsequent effects on the egress system? Similar questions can be posed for other fire protection system components and subsystems.

**A.5.5.3.8(3)** The exemption is applied to each active or passive fire protection system individually and requires two different types of information to be developed by analysis and approved by the authority having jurisdiction. System reliability is to be analyzed and accepted. Design performance in the absence of the system is also to be analyzed and accepted, but acceptable performance does not require fully meeting the stated goals and objectives. It might not be possible to meet fully the goals and objectives if a key system is unavailable, and yet no system is totally reliable. The authority having jurisdiction will determine

which level of performance, possibly short of the stated goals and objectives, is acceptable, given the very low probability (i.e., the system’s unreliability probability) that the system will not be available.

#### 5.5.4 Design Fire Scenarios Data.

**5.5.4.1** Each design fire scenario used in the performance-based design proposal shall be translated into input data specifications, as appropriate for the calculation method or model.

**5.5.4.2** Any design fire scenario specifications that the design analyses do not explicitly address or incorporate and that are, therefore, omitted from input data specifications shall be identified, and a sensitivity analysis of the consequences of that omission shall be performed.

Paragraph 5.5.4.2 is included to remind the designer that even if every design fire specification cannot be incorporated into a specific design tool or verification method, each must be addressed in the analysis in some manner. For example, an evacuation model that does not address crowding or queuing effects does not address the particular delay hazard initiated by Design Fire Scenario 2, which reduces the means of egress from the building. Additionally, many fire effects models do not address barrier breach, and, therefore, fail to incorporate the defining characteristics of Design Fire Scenario 4, a concealed space fire threatening an adjacent, occupied space.

Despite the fact that these models do not incorporate particular aspects of the design fire scenario specifications, those aspects must be addressed in the design, either through conservative assumptions supported by accepted technical resources or test data or by comparative techniques that will conservatively account for these effects. A sensitivity analysis should be performed on the omission of these aspects, as well as the techniques used to account for their omission.

**5.5.4.3** Any design fire scenario specifications modified in input data specifications, because of limitations in test methods or other data-generation procedures, shall be identified, and a sensitivity analysis of the consequences of the modification shall be performed.

Paragraph 5.5.4.3 essentially expresses the same concern as 5.5.4.2; however, the concern arises more from a limitation of available data than from a limitation of the model. Typically, both types of limitations will be present. When analyzing Design Fire Scenario 2, there may not be a model available that accounts for crowding or queuing, or there may be only a model that assumes uniform speeds and sizes of occupants due to lack of data on expected ranges of occupant characteristics. These limitations will tend to produce an estimated speed of evacuation, in the absence of turbulence, that is unrealistically fast. Additionally, with regard to Design Fire Scenario 4, there may be no model to determine the time to barrier breach and insufficient data on burn-through or failure behavior of the materials and assemblies proposed in the design.

## 5.6\* Evaluation of Proposed Designs

**A.5.6** The *SFPE Engineering Guide to Performance-Based Fire Protection* outlines a process for evaluating whether trial designs meet the performance criteria during the design fire scenarios. Additional information on reviewing the evaluation of a performance-based design can be found in the *SFPE Code Official's Guide to Performance-Based Design Review*.

The procedures described in **Sections 5.2** and **5.4** identify required design fire scenarios among the design fire scenarios within which a proposed fire safety design is required to perform and the associated untenable conditions that are to be avoided in order to maintain life safety. **Section 5.6** discusses methods that form the link from the scenarios and criteria to the goals and objectives.

Assessment methods are used to demonstrate that the proposed design will achieve the stated goals/objectives by providing information indicating that the performance criteria of **Section 5.2** can be adequately met. Assessment methods are permitted to be either tests or modeling.

**Tests.** Test results can be directly used to assess a fire safety design when they accurately represent the scenarios developed by using **Section 5.4** and provide output data matching the performance criteria in **Section 5.2**. Because the performance criteria for this *Code* are stated in terms of human exposure to lethal fire effects, no test will suffice. However, tests will be needed to produce data for use in models and other calculation methods.

**Standardized Tests.** Standardized tests are conducted on various systems and components to determine whether they meet some predetermined, typically prescriptive criteria. Results are given on a pass/fail basis — the test specimen either does or does not meet the pre-established criteria. The actual performance of the test specimen is not usually recorded.

**Scale.** Tests can be either small, intermediate, or full scale. Small-scale tests are used to test activation of detection and suppression devices and the flammability and toxicity of materials. Usually, the item to be tested is placed within the testing device or apparatus. Intermediate-scale tests can be used to determine the adequacy of system components — for example, doors and windows — as opposed to entire systems. The difference between small- and intermediate-scale tests is usually one of definition provided by those conducting the test. Full-scale tests are typically used to test building and structural components or entire systems. The difference between intermediate- and large-scale tests is also subject to the definition of those performing the test. Full-scale tests are intended to most closely depict performance of the test subject as installed in the field; that is, most closely represent real world performance.

Full-scale building evacuations can provide information on how the evacuation of a structure is likely to occur for an existing building with a given population without subjecting occupants to the real physical or psychological effects of a fire.

**Data Uses.** The data obtained from standardized tests have three uses for verification purposes. First, the test results can be used instead of a model. This use is typically the role of full-scale test results. Second, the test results can be used as a basis for validating the model. The model predictions match well with the test results. Therefore, the model can be used in situations similar to the test scenario. Third, the test results can be used as input to models. This is typically the use of small-scale tests, specifically flammability tests.

**Start-Up Test.** Start-up test results can be used to demonstrate that the fire safety system performs as designed. The system design might be based on modeling. If the start-up test indicates a deficiency, the system needs to be adjusted and retested until it can be demonstrated that the design can meet the performance criteria. Typically, start-up tests apply only to the installation to which they are designed.

**Experimental Data.** Experimental data from nonstandardized tests can be used when the specified scenario and the experimental setup are similar. Typically, experimental data are applicable to a greater variety of scenarios than are standardized test results.

**Human and Organizational Performance Tests.** Certain tests determine whether inputs used to determine human performance criteria remain valid during the occupancy of a building. Tests of human and organizational performance might include any of the following:

- (1) Measuring evacuation times during fire drills
- (2) Querying emergency response team members to determine whether they know required procedures
- (3) Conducting field tests to ensure that emergency response team members can execute tasks within predetermined times and accuracy limits

Design proposals should include descriptions of any tests needed to determine whether stated goals, objectives, and performance criteria are being met.

**Modeling.** Models can be used to predict the performance criteria for a given scenario. Because of the limitations on using only tests for this purpose, models are expected to be used in most, if not all, performance-based design assessments.

The effect of fire and its toxic products on the occupants can be modeled, as can the movement and behavior of occupants during the fire. The term *evacuation model* will be used to describe models that predict the location and movements of occupants, and the term *tenability model* will be used to describe models that predict the effects on occupants of specified levels of exposure to fire effects.

**Types of Fire Models.** Fire models are used to predict fire-related performance criteria. Fire models can be either probabilistic or deterministic. Several types of deterministic models are available: computational fluid dynamics (CFD or field) models, zone models, purpose-built models, and hand calculations.

Probabilistic fire models are also available but are less likely to be used for this purpose.

Probabilistic fire models use the probabilities as well as the severity of various events as the basis of evaluation. Some probabilistic models incorporate deterministic models, but are not required to do so. Probabilistic models attempt to predict the likelihood or probability that events or severity associated with an unwanted fire will occur, or they predict the “expected loss,” which can be thought of as the probability-weighted average severity across all possible scenarios. Probabilistic models can be manifested as fault or event trees or other system models that use frequency or probability data as input. These models tend to be manifested as computer software, but are not required to do so. Furthermore, the discussion that follows under “Sources of Models” can also be applied to probabilistic models, although it concentrates on deterministic models.

CFD models can provide more accurate predictions than other deterministic models, because they divide a given space into many smaller-volume spaces. However, since they are still models, they are not absolute in their depiction of reality. In addition, they are much more expensive to use, because they are computationally intensive. Because of their expense, complexity, and intensive computational needs, CFD models require much greater scrutiny than do zone models.

It is much easier to assess the sensitivity of different parameters with zone models, because they generally run much faster and the output is much easier to interpret. Prediction of fire growth and spread has a large number of variables associated with it.

Purpose-built models (also known as stand-alone models) are similar to zone models in their ease of use. However, purpose-built models do not provide a comprehensive model. Instead, they predict the value of one variable of interest. For example, such a model can predict the conditions of a ceiling jet at a specified location under a ceiling, but a zone model would “transport” those conditions throughout the enclosure.

Purpose-built models might or might not be manifested as computer software. Models that are not in the form of software are referred to as hand calculations. Purpose-built models are, therefore, simple enough that the data management capabilities of a computer are not necessary. Many of the calculations are found in the *SFPE Handbook of Fire Protection Engineering*.

*Types of Evacuation Models.* Four categories of evacuation models can be considered: single-parameter estimation methods, movement models, behavioral simulation models, and tenability models.

*Single-parameter estimation methods* are generally used for simple estimates of movement time. They are usually based on equations derived from observations of movement in nonemergency situations. They can be hand calculations or simple computer models. Examples include calculation methods for flow

times based on widths of exit paths and travel times based on travel distances. Sources for these methods include the *SFPE Handbook of Fire Protection Engineering* and the *NFPA Fire Protection Handbook*.

*Movement models* generally handle large numbers of people in a network flow similar to water in pipes or ball bearings in chutes. They tend to optimize occupant behavior, resulting in predicted evacuation times that can be unrealistic and far from conservative. However, they can be useful in an overall assessment of a design, especially in early evaluation stages where an unacceptable result with this sort of model indicates that the design has failed to achieve the life safety objectives.

*Behavioral simulation models* take into consideration more of the variables related to occupant movement and behavior. Occupants are treated as individuals and can have unique characteristics assigned to them, allowing a more realistic simulation of the design under consideration. However, given the limited availability of data for the development of these models, for their verification by their authors, or for input when using them, their predictive reliability is questionable.

*Tenability Models.* In general, tenability models will be needed only to automate calculations for the time-of-exposure effect equations referenced in [A.5.2.2](#).

*Other Models.* Models can be used to describe combustion (as noted, most fire models only characterize fire effects), automatic system performance, and other elements of the calculation. There are few models in common use for these purposes, so they are not further described here.

*Sources of Models.* A compendia of computer fire models are found in the *SFPE Computer Software Directory* and in Olenick, S. and Carpenter, D., “An Updated International Survey of Computer Models for Fire and Smoke,” *Journal of Fire Protection Engineering*, 13, 2, 2003, pp. 87–110. Within these references are models that were developed by the Building Fire Research Laboratory of the National Institute of Standards and Technology, which can be downloaded from the Internet at <http://www.bfrl.nist.gov/864/fmabs.html>. Evacuation models are discussed in the *SFPE Handbook of Fire Protection Engineering* and the *NFPA Fire Protection Handbook*.

*Verification and validation.* Models should undergo verification and validation to ensure that they are appropriate for their intended use. “Verification” is a check of the math used in the models. “Validation” is a check of the physics used in the model. The *SFPE Guidelines for Substantiating a Fire Model for a Given Application* provides a process for verifying and validating models.

The design professional should present the proposal, and the authority having jurisdiction, when deciding whether to approve a proposal, should consider the strength of the evidence presented for the validity, accuracy, relevance, and precision of the proposed methods. An element in establishing the strength

of scientific evidence is the extent of external review and acceptance of the evidence by peers of the authors of that evidence.

Models have limitations. Most are not user friendly, and experienced users are able to construct more reasonable models and better interpret output than are novices. For these reasons, the third-party review and equivalency provisions of 5.1.4 and 5.3.3 are provided. The intent is not to discourage the use of models, only to indicate that they should be used with caution by those who are well versed in their nuances.

*Input Data.* The first step in using a model is to develop the input data. The heat release rate curve specified by the user is the driving force of a fire effects model. If this curve is incorrectly defined, the subsequent results are not usable. In addition to the smoldering and growth phases that will be specified as part of the scenario definition, two additional phases are needed to complete the input heat release rate curve — steady burning and burnout.

Steady burning is characterized by its duration, which is a function of the total amount of fuel available to be burned. In determining the duration of this phase, the designer needs to consider how much fuel has been assumed to be consumed in the smoldering and growth phases and how much is assumed to be consumed in the burnout phase that follows. Depending on the assumptions made regarding the amount of fuel consumed during burnout, the time at which this phase starts is likely to be easy to determine.

The preceding discussion assumes that the burning objects are solid (e.g., tables and chairs). If liquid or gaseous fuels are involved, the shape of the curve will be different. For example, smoldering is not relevant for burning liquids or gases, and the growth period is very short, typically measured in seconds. Peak heat release rate can depend primarily on the rate of release, on the leak rate (gases and liquid sprays), or on the extent of spill (pooled liquids). The steady burning phase is once again dependent on the amount of fuel available to burn. Like the growth phase, the burnout phase is typically short (e.g., closing a valve), although it is conceivable that longer times might be appropriate, depending on the extinguishment scenario.

Material properties are usually needed for all fuel items, both initial and secondary, and the enclosure surfaces of involved rooms or spaces.

For all fires of consequence, it is reasonable to assume that the fire receives adequate ventilation. If there is insufficient oxygen, the fire will not be sustained. An overabundance of oxygen is only a concern in special cases (e.g., hermetically sealed spaces) where a fire might not occur due to dilution of the fuel (i.e., a flammable mixture is not produced). Therefore, given that the scenarios of interest will occur in nonhermetically sealed enclosures, it is reasonable to assume that adequate ventilation is available and that, if a fire starts, it will continue to burn until it either runs out of fuel or is extinguished by other means. The only variable that might need to be assumed is the total vent width.

Maximum fire extent is affected by two geometric aspects: burning object proximity to walls and overall enclosure dimensions.

The room dimensions affect the time required for a room to flashover. For a given amount and type of fuel, under the same ventilation conditions, a small room will flashover before a large room. In a large room with a small amount of fuel, a fire will behave as if it is burning outside — that is, adequate oxygen for burning and no concentration of heat exist. If the fuel package is unchanged but the dimensions of the room are decreased, the room will begin to have an effect on the fire, assuming adequate ventilation. The presence of the relatively smaller enclosure results in the buildup of a hot layer of smoke and other products of combustion under the ceiling. This buildup, in turn, feeds more heat back to the seat of the fire, which results in an increase in the pyrolysis rate of the fuel and, thus, increases the amount of heat energy released by the fire. The room enclosure surfaces themselves also contribute to this radiation feedback effect.

Probabilistic data are expressed as either a frequency (units of inverse time) or a probability (unitless, but applicable to a stated period of time). An example of the former is the expected number of failures per year, and the range of the latter is between zero and one, inclusive. Probabilities can be either objective or subjective. Subjective probabilities express a degree of belief that an event will occur. Objective probabilities are based on historical data and can be expressed as a reliability of an item, such as a component or a system.

**5.6.1 General.** A proposed design's performance shall be assessed relative to each performance objective in Section 4.2 and each applicable scenario in 5.5.3, with the assessment conducted through the use of appropriate calculation methods. The authority having jurisdiction shall approve the choice of assessment methods.

The verification process starts with the submittal of a proposed design to the authority having jurisdiction. If the AHJ does not consider itself qualified to perform an adequate review of the performance-based design, the AHJ might specify a qualified third-party reviewer. The owner typically incurs the expense associated with the third-party review process.

The first step of the verification process is to identify the goals and the objectives relating to those goals. Attention must be paid to both those objectives that apply to the facility as a whole and those that apply only to limited aspects of the facility. The AHJ's purpose in this review is to determine whether the designer/owner's objectives are commensurate with the community's objectives. Next, the AHJ reviews the performance criteria that relate to each of the objectives for consistency and reasonableness. Do the objectives form a comprehensive package? Are they realistic? The next step involves the characteristics of that which is being protected — people, property, and so on. Once again, a comprehensive, cohesive set of assumptions is sought.

Essentially, the verification process ensures that the logic flow and justification for the choices made are sound; the links between the components are checked to ensure that the design process flows — objectives are to be met by demonstrating that criteria have been achieved through the judicious use of verification methods. Assumptions need to be reasonable, consistent, comprehensive, cohesive, and supported by adequate references.

Presumably, the designer's proposal ensures that all criteria are met for all scenarios. Ultimately, the AHJ is interested in determining whether the designer did a credible job so that the predicted results provide a sufficient margin of safety to allow the design to be approved. Because of the complexity involved in determining credibility, many discussions can be anticipated between the AHJ, the designer, and, if used, the third-party reviewer.

**5.6.2 Use.** The design professional shall use the assessment methods to demonstrate that the proposed design will achieve the goals and objectives, as measured by the performance criteria in light of the safety margins and uncertainty analysis, for each scenario, given the assumptions.

The choice of which model to select depends on the objectives, the performance criteria to be predicted, and the scenarios to be considered. The model selected should use most, if not all, of the input data specifications and must produce design output that can be directly compared to the performance criteria selected as a baseline for the analysis. Two criteria are usually of greatest interest: the upper layer temperature and the height of the smoke layer interface. If the objective is to reduce property damage in a telephone vault, then a purpose-built model that predicts smoke filling is adequate. If the objective is the life safety of those not intimate with the fire — both within the room of origin and along adjacent egress paths — in a rectilinear room, then a zone model is adequate. If life safety is the objective and the fire occurs in a more geometrically challenging configuration (e.g., an amusement park fun house or enclosed amusement ride), then a field model is appropriate. If the effects on occupants are to be estimated, an evacuation or toxicity model needs to be used.

### 5.6.3 Input Data.

**5.6.3.1 Data.** Input data for computer fire models shall be obtained in accordance with ASTM E 1591, *Standard Guide for Obtaining Data for Deterministic Fire Models*. Data for use in analytical models that are not computer-based fire models shall be obtained using appropriate measurement, recording, and storage techniques to ensure the applicability of the data to the analytical method being used.

**5.6.3.2 Data Requirements.** A complete listing of input data requirements for all models, engineering methods, and other calculation or verification methods required or proposed as part of the performance-based design shall be provided.

Documentation of the assumptions made by the model user while developing the input data is critical. If the model user does not explicitly state the values used and the references from which they are taken, the credibility of the analysis is decreased.

**5.6.3.3\* Uncertainty and Conservatism of Data.** Uncertainty in input data shall be analyzed and, as determined appropriate by the authority having jurisdiction, addressed through the use of conservative values.

**A.5.6.3.3** Procedures used to develop required input data need to preserve the intended conservatism of all scenarios and assumptions. Conservatism is only one means to address the uncertainty inherent in calculations and does not eliminate the need to consider safety factors, sensitivity analysis, and other methods of dealing with uncertainty. The *SFPE Guidelines for Substantiating a Fire Model for a Given Application* outlines a process for identifying and treating uncertainty and other inaccuracies introduced through the use of fire models.

**5.6.4\* Output Data.** The assessment methods used shall accurately and appropriately produce the required output data from input data, based on the design specifications, assumptions, and scenarios.

**A.5.6.4** An assessment method translates input data, which might include test specifications, parameters, or variables for modeling, or other data, into output data, which are measured against the performance criteria. Computer fire models should be evaluated to ensure that they are appropriate for their intended use in accordance with the *SFPE Guidelines for Substantiating a Fire Model for a Given Application*.

The design team selects verification methods that produce output data that can be directly compared to the performance criteria. Any additional output data needs to be included with the analysis results and submitted to the authority having jurisdiction for review.

**5.6.5 Validity.** Evidence shall be provided to confirm that the assessment methods are valid and appropriate for the proposed building, use, and conditions.

If the chosen assessment method is a computer model, then the validity of the model, with regard to the scenario being modeled, might be in question. By choosing a particular model, the designer is tacitly assuming that the model is valid for the particular scenario. Two situations are possible: either the assumption is correct (and there's nothing to worry about) or the assumption is not correct. If the assumption is not correct, this does not immediately invalidate the entire analysis. Part of the argument for using a particular model is that it is the only tool available (i.e., choice is constrained by the available resources) that can be used. If a sensitivity analysis is also performed, this will go a long way in demonstrating that a range of conditions has been considered and the "real" answer has been adequately bounded by the results of the sensitivity analysis.

## 5.7\* Safety Factors

Approved safety factors shall be included in the design methods and calculations to reflect uncertainty in the assumptions, data, and other factors associated with the performance-based design.

**A.5.7** The assessment of precision required in 5.8.2 will require a sensitivity and uncertainty analysis, which can be translated into safety factors.

*Sensitivity Analysis.* The first run a model user makes should be labeled as the base case, using the nominal values of the various input parameters. However, the model user should not rely on a single run as the basis for any performance-based fire safety system design. Ideally, each variable or parameter that the model user made to develop the nominal input data should have multiple runs associated with it, as should combinations of key variables and parameters. Thus, a sensitivity analysis should be conducted that provides the model user with data that indicate how the effects of a real fire might vary and how the response of the proposed fire safety design might also vary.

The interpretation of a model's predictions can be a difficult exercise if the model user does not have knowledge of fire dynamics or human behavior.

*Reasonableness Check.* The model user should first try to determine whether the predictions actually make sense; that is, whether they do not upset intuition or preconceived expectations. Most likely, if the results do not pass this test, an input error has been committed.

Sometimes the predictions appear to be reasonable but are, in fact, incorrect. For example, a model can predict higher temperatures farther from the fire than closer to it. The values themselves might be reasonable; for example, they are not hotter than the fire, but they do not “flow” down the energy as expected.

A margin of safety can be developed using the results of the sensitivity analysis in conjunction with the performance criteria to provide the possible range of time during which a condition is estimated to occur.

Safety factors and margin of safety are two concepts used to quantify the amount of uncertainty in engineering analyses. Safety factors are used to provide a margin of safety and represent, or address, the gap in knowledge between the theoretically perfect model — reality — and the engineering models that can only partially represent reality.

Safety factors can be applied either to the predicted level of a physical condition or to the time at which the condition is predicted to occur. Thus, a physical or a temporal safety factor, or both, can be applied to any predicted condition. A predicted condition (i.e., a parameter's value) and the time at which it occurs are best represented as distributions. Ideally, a computer fire model predicts the expected or nominal value of the distribution. Safety factors are intended to represent the spread of the distributions.

Given the uncertainty associated with data acquisition and reduction, and the limitations of computer modeling, any

condition predicted by a computer model can be thought of as an expected or nominal value within a broader range. For example, an upper layer temperature of 1110°F (600°C) is predicted at a given time. If the modeled scenario is then tested (i.e., full-scale experiment based on the computer model's input data), the actual temperature at that given time could be 1185°F or 1085°F (640°C or 585°C). Therefore, the temperature should be reported as 1110°F + 75°F/–25°F (600°C + 40°C/–15°C) or as a range of 1085°F to 1185°F (585°C to 640°C).

Ideally, predictions are reported as a nominal value, a percentage, or an absolute value. As an example, an upper layer temperature prediction could be reported as “1110°F (600°C), 55°F (30°C),” or “1110°F (600°C), 5 percent.” In this case, the physical safety factor is 0.05 (i.e., the amount by which the nominal value should be degraded and enhanced). Given the state-of-the-art of computer fire modeling, this is a very low safety factor. Physical safety factors tend to be on the order of tens of percent. A safety factor of 50 percent is not unheard of.

Part of the problem in establishing safety factors is that it is difficult to state the percentage or range that is appropriate. These values can be obtained when the computer model predictions are compared to test data. However, using computer fire models in a design mode does not facilitate this comparison, due to the following:

- (1) The room being analyzed has not been built yet.
- (2) Test scenarios do not necessarily depict the intended design.

A sensitivity analysis should be performed, based on the assumptions that affect the condition of interest. A base case that uses all nominal values for input parameters should be developed. The input parameters should be varied over reasonable ranges, and the variation in predicted output should be noted. This output variation can then become the basis for physical safety factors.

The temporal safety factor addresses the issue of when a condition is predicted and is a function of the rate at which processes are expected to occur. If a condition is predicted to occur 2 minutes after the start of the fire, this prediction can be used as a nominal value. A process similar to that already described for physical safety factors can also be employed to develop temporal safety factors. In such a case, however, the rates (e.g., rates of heat release and toxic product generation) will be varied instead of absolute values (e.g., material properties).

The margin of safety can be thought of as a reflection of societal values and can be imposed by the authority having jurisdiction for that purpose. Because the time for which a condition is predicted will most likely be the focus of the authority having jurisdiction (e.g., the model predicts that occupants will have 5 minutes to safely evacuate), the margin of safety will be characterized by temporal aspects and tacitly applied to the physical margin of safety.

Escaping the harmful effects of fire (or mitigating them) is, effectively, a race against time. When assessing fire safety system designs based on computer model predictions, the choice of an acceptable time is important. When an authority having

jurisdiction is faced with the predicted time of untenability, a decision needs to be made regarding whether sufficient time is available to ensure the safety of building occupants. The authority having jurisdiction is assessing the margin of safety. Is there sufficient time to get everyone out safely? If the authority having jurisdiction feels that the predicted egress time is too close to the time of untenability, the authority having jurisdiction can impose an additional period of time that the designer will have to incorporate into the system design. In other words, the authority having jurisdiction can impose a greater margin of safety than that originally proposed by the designer.

In addition to justification of the baseline case input data specification values, the design team should include an allowable range of values determined using a sensitivity analysis. The design team should investigate the effects of varying key components and variables independently and in combination and should document the effects of this variation.

## 5.8 Documentation Requirements

**5.8.1\* General.** All aspects of the design, including those described in 5.8.2 through 5.8.14, shall be documented. The format and content of the documentation shall be acceptable to the authority having jurisdiction.

**A.5.8.1** The *SFPE Engineering Guide to Performance-Based Fire Protection* describes the documentation that should be provided for a performance-based design.

Proper documentation of a performance-based design is critical to design acceptance and construction. Proper documentation will also ensure that all parties involved understand the factors necessary for the implementation, maintenance, and continuity of the fire protection design. If attention to details is maintained in the documentation, there should be little dispute during approval, construction, start-up, and use.

Poor documentation could result in rejection of an otherwise good design, poor implementation of the design, inadequate system maintenance and reliability, and an incomplete record for future changes or for testing the design forensically.

The maintenance of proper documentation plays an important role in at least three phases of the building life cycle.

1. The documentation needs to be used by the AHJ and other design team members during the design acceptance, construction, and approval that lead to a certificate of occupancy.
2. The documentation needs to be used whenever any potential rehabilitation or change in use is considered.
3. The documentation needs to be used in preparation of the yearly warrant of fitness that certifies compliance with the conditions and limitations of the performance-based design as required by 4.6.9.2.

**5.8.2\* Technical References and Resources.** The authority having jurisdiction shall be provided with sufficient documentation to support the validity, accuracy, relevance, and precision of the proposed methods. The engineering standards, calculation methods, and other forms of scientific information provided shall be appropriate for the particular application and methodologies used.

**A.5.8.2** The sources, methodologies, and data used in performance-based designs should be based on technical references that are widely accepted and used by the appropriate professions and professional groups. This acceptance is often based on documents that are developed, reviewed, and validated under one of the following processes:

- (1) Standards developed under an open consensus process conducted by recognized professional societies, codes or standards organizations, or governmental bodies
- (2) Technical references that are subject to a peer review process and published in widely recognized peer-reviewed journals, conference reports, or other publications
- (3) Resource publications, such as the *SFPE Handbook of Fire Protection Engineering*, which are widely recognized technical sources of information

The following factors are helpful in determining the acceptability of the individual method or source:

- (1) Extent of general acceptance in the relevant professional community, including peer-reviewed publication, widespread citation in the technical literature, and adoption by or within a consensus document
- (2) Extent of documentation of the method, including the analytical method itself, assumptions, scope, limitations, data sources, and data reduction methods
- (3) Extent of validation and analysis of uncertainties, including comparison of the overall method with experimental data to estimate error rates, as well as analysis of the uncertainties of input data, uncertainties and limitations in the analytical method, and uncertainties in the associated performance criteria
- (4) Extent to which the method is based on sound scientific principles
- (5) Extent to which the proposed application is within the stated scope and limitations of the supporting information, including the range of applicability for which there is documented validation, and considering factors such as spatial dimensions, occupant characteristics, and ambient conditions, which can limit valid applications

In many cases, a method will be built from, and will include, numerous component analyses. Such component analyses should be evaluated using the same acceptability factors that are applied to the overall method, as outlined in items (1) through (5).

A method to address a specific fire safety issue, within documented limitations or validation regimes, might not exist. In such

a case, sources and calculation methods can be used outside of their limitations, provided that the design team recognizes the limitations and addresses the resulting implications.

The technical references and methodologies to be used in a performance-based design should be closely evaluated by the design team and the authority having jurisdiction, and possibly by a third-party reviewer. The strength of the technical justification should be judged using criteria in items (1) through (5). This justification can be strengthened by the presence of data obtained from fire testing.

**5.8.3 Building Design Specifications.** All details of the proposed building design that affect the ability of the building to meet the stated goals and objectives shall be documented.

**5.8.4 Performance Criteria.** Performance criteria, with sources, shall be documented.

**5.8.5 Occupant Characteristics.** Assumptions about occupant characteristics shall be documented.

**5.8.6 Design Fire Scenarios.** Descriptions of design fire scenarios shall be documented.

**5.8.7 Input Data.** Input data to models and assessment methods, including sensitivity analyses, shall be documented.

**5.8.8 Output Data.** Output data from models and assessment methods, including sensitivity analyses, shall be documented.

**5.8.9 Safety Factors.** The safety factors utilized shall be documented.

**5.8.10 Prescriptive Requirements.** Retained prescriptive requirements shall be documented.

#### 5.8.11\* Modeling Features.

**A.5.8.11** Documentation for modeling should conform to ASTM E 1472, *Standard Guide for Documenting Computer Software for Fire Models*, although most, if not all, models were originally developed before this standard was promulgated. Information regarding the use of the model DETACT-QS can be found in the *SFPE Engineering Guide—the Evaluation of the Computer Fire Model DETACT-QS*.

**5.8.11.1** Assumptions made by the model user, and descriptions of models and methods used, including known limitations, shall be documented.

**5.8.11.2** Documentation shall be provided to verify that the assessment methods have been used validly and appropriately to address the design specifications, assumptions, and scenarios.

**5.8.12 Evidence of Modeler Capability.** The design team's relevant experience with the models, test methods, databases, and other assessment methods used in the performance-based design proposal shall be documented.

**5.8.13 Performance Evaluation.** The performance evaluation summary shall be documented.

**5.8.14 Use of Performance-Based Design Option.** Design proposals shall include documentation that provides anyone involved in the ownership or management of the building with notification of the following:

- (1) Approval of the building as a performance-based design with certain specified design criteria and assumptions
- (2) Need for required re-evaluation and reapproval in cases of remodeling, modification, renovation, change in use, or change in established assumptions

# Classification of Occupancy and Hazard of Contents

Chapter 6 addresses the following considerations needed for accurately determining which *Code* provisions apply to a specific building:

1. Classification of occupancy
2. Choice of treating multiple occupancies as either mixed occupancies or separated occupancies
3. Categorization of the relative hazard presented by the contents or use of the building

Proper classification of the occupancy is crucial; since the *Code* is not a “one size fits all” document, the selection of the proper occupancy is of para-mount importance to ensure that the correct chapters and sections of the *Code* are used. The occupancy classification scheme uses general descriptions of each occupancy (e.g., assembly, educational, day-care, or health care). The annex text that accompanies each of the occupancy classifications provides lists of the most common building uses for each classification.

Occupancy classification of a building often encompasses more than one category. It is common for multiple occupancy types to coexist within a single building. For example, a hotel often consists of a multiple occupancy that includes hotel, assembly, mercantile, and business occupancies. Paragraph 6.1.14.1.1 requires that multiple occupancies be treated as either mixed occupancies or separated occupancies. An office building with a newsstand and sundries shop located off the main lobby might be classified wholly as a business occupancy by considering the mercantile use as incidental to the predominant business use as permitted by 6.1.14.1.3(1), thus avoiding the provisions applicable to a multiple occupancy.

Hazard of contents, as addressed in Section 6.2, describes the relative hazard associated with the contents and operational aspects of the building. *Hazard of contents* is a relative term that is used to describe the potential threat to occupants from a fire that occurs in building contents in a given occupancy type.

---

## 6.1 Classification of Occupancy

Each of the occupancy groupings addressed by Chapter 6 was developed to reflect the design features, usage patterns, and unique life safety needs of occupants who are characteristic of a given occupancy. This approach was used to assess the degree to which the features contained in the core chapters need to be combined to achieve the minimum level of life safety necessary

for an occupancy. It is extremely important that the correct occupancy classification be determined, because the *Code* requirements differ for each type of occupancy. Improper classification might result in an inadequate level of life safety or overspending on nonrequired items. The occupancy groupings are as follows:

1. *Assembly*. Assembly occupancies generally contain large numbers of people who are unfamiliar with the space and are, therefore, subject to indecision regarding the best means of egress in an emergency.

2. *Educational*. Educational occupancies primarily include the large numbers of young people found in school buildings.

3. *Day-care*. Day-care occupancies contain both young and adult clients who are under the supervision of adults other than their relatives or legal guardians. In cases where day-care occupancies cater to preschool-age children, the occupants might need to be carried out of the facility during evacuation.

4. *Health care*. Health care occupancies are characterized by occupants who are incapable of self-preservation and occupy the occupancy on an inpatient basis. For occupancies that provide health care services on an outpatient basis, see the description that follows on ambulatory health care occupancies. In a health care occupancy, the occupants may not be able to use exits, regardless of the number of exits provided. Occupants might be immobile, connected to monitoring equipment, debilitated, or recovering from surgery; or they might be disabled in some other way. The *Code*, in such instances, calls for a defend-in-place design strategy that uses horizontal movement and compartmentation. It recognizes that the occupants are to be provided enough protection to enable them to survive the fire by remaining in the structure, at least temporarily.

5. *Ambulatory health care*. Ambulatory health care occupancies are similar to health care occupancies in that the occupants are generally incapable of self-preservation, but, unlike health care occupancies, the patients receive medical care on an outpatient basis. In many cases, the treatment causes the patient to be incapable of self-preservation. In other cases, a procedure, such as administering general anesthesia that is needed in conjunction with a treatment, renders the patient incapable of self-preservation. In yet other cases, the patient arrives at the ambulatory health care facility incapable of self-preservation due to an injury or illness, as is common in an emergency or urgent care outpatient facility. The ambulatory health care occupancy operates on an outpatient basis, so no individual patient occupies the building for a period of 24 hours or more.

**6. Detention and correctional.** Detention and correctional occupancies, as in the case of health care occupancies, house occupants who are incapable of self-preservation. In a detention and correctional occupancy, however, the incapability for self-preservation is due to the security imposed on the occupants. Because doors are not unlocked to allow free egress to the public way, the defend-in-place design strategy is used.

**7. Residential.** Residential occupancies are characterized by occupants who are asleep for a portion of the time they occupy the building. The sleeping that takes place is for normal restorative rest, as opposed to the sleeping that takes place in a hospital or residential board and care facility where caretakers are present. Sleeping occupants might be unaware of an incipient fire and might be trapped before egress can occur, thus creating a need for early warning smoke alarms. This occupancy group is further divided into one- and two-family dwellings, lodging or rooming houses, hotels and dormitories, and apartment buildings. Each occupancy in the group has characteristic needs that differ from the others. For this reason, separate chapters of the *Code* address each of these subgroups.

**8. Residential board and care.** Residential board and care occupancies, as in the case of residential occupancies, provide sleeping accommodations. However, the residents also receive personal care services by caretakers who live with the residents. Personal care includes assistance with many of the activities of daily living, such as bathing and dressing. Personal care does not include medical care.

**9. Mercantile.** Mercantile occupancies, as in the case of assembly occupancies, are characterized by large numbers of people who gather in a space that is relatively unfamiliar to them. In addition, mercantile occupancies often contain sizable quantities of combustible contents and use circuitous egress paths that are deliberately arranged to force occupants to travel around displays of materials that are available for sale.

**10. Business.** Business occupancies generally have a lower occupant density than mercantile occupancies, and the occupants are usually more familiar with their surroundings. However, confusing and indirect egress paths are often developed due to office layouts and the arrangement of tenant spaces. The *Code* requirements for such occupancies address the needs of visitors unfamiliar with the building.

**11. Industrial.** Industrial occupancies expose occupants to a wide range of processes and materials of varying hazard. Special-purpose industrial occupancies, which are characterized by large installations of equipment that dominate the space, are addressed separately from general-purpose industrial facilities, which have higher densities of human occupancy.

**12. Storage.** Storage occupancies are characterized by relatively low human occupancy in comparison to building size and by varied hazards associated with the materials stored.

## 6.1.1 General.

**6.1.1.1 Occupancy Classification.** The occupancy of a building or structure, or portion of a building or structure, shall be classified in accordance with 6.1.2 through 6.1.13. Occupancy classification shall be subject to the ruling of the authority having jurisdiction where there is a question of proper classification in any individual case.

Because the appropriate occupancy classification is not always easily determined, the *Code* assigns the authority having jurisdiction (AHJ) the responsibility of determining whether the designer, owner's representative, or other applicable person has correctly classified the occupancy.

**6.1.1.2 Special Structures.** Occupancies in special structures shall conform to the requirements of the specific occupancy chapter, Chapters 12 through 43, except as modified by Chapter 11.

The provision of 6.1.1.2 clarifies that placing an occupancy in a special structure — such as a limited access, underground, water-surrounded, or high-rise building — does not create a unique occupancy. Rather, the occupancy is classified as one of those addressed by Chapters 12 through 42. Chapter 11 is then consulted to identify any permitted leniencies or additional requirements that apply to the special structure.

**6.1.2 Assembly.** For requirements, see Chapters 12 and 13.

**6.1.2.1\* Definition — Assembly Occupancy.** An occupancy (1) used for a gathering of 50 or more persons for deliberation, worship, entertainment, eating, drinking, amusement, awaiting transportation, or similar uses; or (2) used as a special amusement building, regardless of occupant load.

**A.6.1.2.1** Assembly occupancies might include the following:

- (1) Armories
- (2) Assembly halls
- (3) Auditoriums
- (4) Bowling lanes
- (5) Club rooms
- (6) College and university classrooms, 50 persons and over
- (7) Conference rooms
- (8) Courtrooms
- (9) Dance halls
- (10) Drinking establishments
- (11) Exhibition halls
- (12) Gymnasiums
- (13) Libraries
- (14) Mortuary chapels
- (15) Motion picture theaters
- (16) Museums
- (17) Passenger stations and terminals of air, surface, underground, and marine public transportation facilities

- (18) Places of religious worship
- (19) Pool rooms
- (20) Recreation piers
- (21) Restaurants
- (22) Skating rinks
- (23) Special amusement buildings, regardless of occupant load
- (24) Theaters

Assembly occupancies are characterized by the presence or potential presence of crowds with attendant panic hazard in case of fire or other emergency. They are generally or occasionally open to the public, and the occupants, who are present voluntarily, are not ordinarily subject to discipline or control. Such buildings are ordinarily not used for sleeping purposes. Special conference rooms, snack areas, and other areas incidental to, and under the control of, the management of other occupancies, such as offices, fall under the 50-person limitation.

Restaurants and drinking establishments with an occupant load of fewer than 50 persons should be classified as mercantile occupancies.

Occupancy of any room or space for assembly purposes by fewer than 50 persons in another occupancy, and incidental to such other occupancy, should be classified as part of the other occupancy and should be subject to the provisions applicable thereto.

For special amusement buildings, see 12.4.8 and 13.4.8.

### 6.1.2.2 Other. (Reserved)

Exhibit 6.1 depicts an assembly occupancy.

The definition in item (1) of 6.1.2.1 utilizes thresholds that must be met in order for an occupancy to qualify as an assembly occupancy. In the case of assembly occupancies, the thresholds relate to number of occupants and use of the space. Both the occupant number and use thresholds must be met [except for

Exhibit 6.1

An assembly occupancy. (© Álvaro Germán Vilela, Dreamstime.com)

special amusement buildings, as addressed in item (2) of 6.1.2.1, for which the number of occupants is not germane] in order to qualify as an assembly occupancy. For example, a situation in which 40 persons gather for entertainment fits one of the listed assembly use criteria, but not the minimum 50-person criterion, so such an assemblage of persons is not an assembly occupancy. Similarly, a situation in which 60 persons occupy work cubicles in an office setting fits the minimum 50-person criterion, but not any of the assembly use criteria, so such an assemblage of persons is not an assembly occupancy.

Item (2) of 6.1.2.1 clarifies that a special amusement building is an assembly occupancy, even if the occupant load is fewer than 50 persons. If this were not the case, the house of horror amusement building at a carnival, for example, could be treated as a business occupancy, because it does not have the minimum 50-person occupant load typically associated with an assembly occupancy, and the necessary level of life safety might not be provided. As an assembly occupancy, a special amusement building is subject to the provisions of Chapter 12 or Chapter 13. Because such buildings purposely confound the egress path and further confuse the occupants with sound and lighting effects, they need to meet the special requirements of 12.4.8 or 13.4.8.

For other than special amusement buildings, the threshold at which an assembly use becomes an assembly occupancy is the 50-person occupant load.

There is no Code-sanctioned occupancy called a *small assembly occupancy*. An occupancy used for the purposes in item (1) of 6.1.2.1 either is or is not an assembly occupancy based on the 50-person criterion [except for special amusement buildings, as addressed in item (2) of 6.1.2.1]. As the fourth paragraph of A.6.1.2.1 advises, small assembly uses are considered part of the predominant occupancy [see 6.1.14.1.3(2)]. Except for special amusement buildings, as addressed in item (2) of 6.1.2.1, there are no assembly occupancies with occupant loads fewer than 50 persons.

**6.1.3 Educational.** For requirements, see Chapters 14 and 15.

**6.1.3.1\* Definition — Educational Occupancy.** An occupancy used for educational purposes through the twelfth grade by six or more persons for 4 or more hours per day or more than 12 hours per week.

**A.6.1.3.1** Educational occupancies include the following:

- (1) Academies
- (2) Kindergartens
- (3) Schools

An educational occupancy is distinguished from an assembly occupancy in that the same occupants are regularly present.

**6.1.3.2 Other Occupancies.** Other occupancies associated with educational institutions shall be in accordance with the appropriate parts of this Code.

**Exhibit 6.2**An educational occupancy. (© Cynthia Farmer, *Dreamstime.com*)

**6.1.3.3 Incidental Instruction.** In cases where instruction is incidental to some other occupancy, the section of this *Code* governing such other occupancy shall apply.

**Exhibit 6.2** depicts an educational occupancy.

An elementary school classroom used for the requisite hours detailed in **6.1.3.1**, with an occupant load of 50 or more, is classified as an educational occupancy, not an assembly occupancy. The assembly occupancy criteria of **6.1.2.1** involve not just the minimum 50-person criterion but also the use criterion of gathering for deliberation, worship, entertainment, eating, drinking, amusement, awaiting transportation, or similar use. See **14.2.5.4** and **15.2.5.4**, which require a second exit access door from any educational occupancy room with an occupant load of more than 50 persons.

Educational occupancies are limited to facilities used for educational purposes through the twelfth grade. A college classroom does not meet this criterion and is classified as a business occupancy or, where the college classroom has an occupant load of 50 or more, as an assembly occupancy.

Incidental instruction, as addressed in **6.1.3.3**, conducted in some other occupancy is permitted to be considered part of that other occupancy and is subject to the provisions applicable to such other occupancy. For example, a developer of learning software might have a test lab where students, under the direction of teaching specialists, test the effectiveness of such software. The laboratory experience does not substitute for the students' normal schooling. The instruction is incidental to the building functioning as a business occupancy. The occupancy is classified as a business occupancy and is subject to the provisions of **Chapter 38** or **Chapter 39**.

**6.1.4 Day Care.** For requirements, see **Chapters 16** and **17**.

**6.1.4.1\* Definition — Day-Care Occupancy.** An occupancy in which four or more clients receive care, maintenance, and supervision, by other than their relatives or legal guardians, for less than 24 hours per day.

**A.6.1.4.1** Day-care occupancies include the following:

- (1) Adult day-care occupancies, except where part of a health care occupancy
- (2) Child day-care occupancies
- (3) Day-care homes
- (4) Kindergarten classes that are incidental to a child day-care occupancy
- (5) Nursery schools

In areas where public schools offer only half-day kindergarten programs, many child day-care occupancies offer state-approved kindergarten classes for children who need full-day care. As these classes are normally incidental to the day-care occupancy, the requirements of the day-care occupancy should be followed.

#### **6.1.4.2 Other. (Reserved)**

**Exhibit 6.3** depicts a day-care occupancy.

Day-care occupancies have some similarities to educational occupancies. However, in lieu of educational activity with classroom occupants and teachers, there are activities with clients and staff, with staff serving as caretakers. The clients of a day-care occupancy might be adults. It has become fairly common for elderly adults to attend a day-care facility.

The provision of **6.1.14.1.3(2)** permits a nonresidential use with an occupant load fewer than that established by **Section 6.1** for the occupancy threshold to be considered part of the predominant occupancy where such nonresidential use is incidental to the predominant occupancy. Consider a day-care center for 10 clients where such center occupies less than 1000 ft<sup>2</sup> (93 m<sup>2</sup>) in a 100,000 ft<sup>2</sup> (9300 m<sup>2</sup>) office building. The day-care center is a nonresidential use. The occupancy threshold for day-care occupancy classification is four or more clients per **6.1.4.1**. The day-care center occupies not more than 1 percent of the building area, but it cannot be considered incidental to the

**Exhibit 6.3**A day-care occupancy. (© Designpicssub, *Dreamstime.com*)

business use. Per 6.1.4.1 and 6.1.14.1.3(2), it must be classified as a day-care occupancy. Thus, the building is classified as a multiple occupancy comprised of both a business occupancy and a day-care occupancy. The building must meet the provisions of 6.1.14, including protection as either separated occupancies or mixed occupancies. In other words, the provisions for day-care occupancies must be applied, even though the day-care center is small in comparison to the remainder of the building. Otherwise, the day-care clients would not be adequately protected.

**6.1.5 Health Care.** For requirements, see Chapters 18 and 19.

**6.1.5.1\* Definition — Health Care Occupancy.** An occupancy used to provide medical or other treatment or care simultaneously to four or more patients on an inpatient basis, where such patients are mostly incapable of self-preservation due to age, physical or mental disability, or because of security measures not under the occupants' control.

**A.6.1.5.1** Health care occupancies include the following:

- (1) Hospitals
- (2) Limited care facilities
- (3) Nursing homes

Occupants of health care occupancies typically have physical or mental illness, disease, or infirmity. They also include infants, convalescents, or infirm aged persons.

**6.1.5.2 Other. (Reserved)**

Exhibit 6.4 depicts a health care occupancy.

Chapters 18 and 19 address hospitals, nursing homes, and limited care facilities as health care occupancies. These subclassifications of health care occupancies are defined in 3.3.144, 3.3.142.2, and 3.3.90.2, respectively. The definitions specify that each type of facility accommodates four or more persons. Because 24.1.1.2 permits a living unit housing a family and up to

three outsiders to be classified as a one-family dwelling, a home with three or fewer persons incapable of self-preservation does not constitute a health care occupancy.

The definition of *health care occupancy* in 6.1.5.1 clarifies that it applies to patient care on an inpatient basis. In editions prior to the 2009 Code, the user learned this clarification by inference after reading the definition of *ambulatory health care occupancy*, which clearly stipulates the outpatient criterion. See 18.1.1.1.5, 18.1.1.1.9, 19.1.1.1.5, and 19.1.1.1.9 for criteria related to providing sleeping accommodations for more than 24 hours (i.e., the inpatient criterion). Health care occupancies, if they are to be protected by the provisions of Chapter 18 or Chapter 19, must have at least four inpatients. A health care facility used only for outpatients is addressed by 6.1.6.1 as an ambulatory health care occupancy and is subject to the provisions of Chapter 20 or Chapter 21.

A definition of *birth center* appears in 3.3.33. Also, guidance for whether a birth center is to be classified as a business occupancy or as a health care occupancy is provided in the third paragraph of A.6.1.11.1.

**6.1.6 Ambulatory Health Care.** For requirements, see Chapters 20 and 21.

**6.1.6.1\* Definition — Ambulatory Health Care Occupancy.** An occupancy used to provide services or treatment simultaneously to four or more patients that provides, on an outpatient basis, one or more of the following:

- (1) Treatment for patients that renders the patients incapable of taking action for self-preservation under emergency conditions without the assistance of others
- (2) Anesthesia that renders the patients incapable of taking action for self-preservation under emergency conditions without the assistance of others
- (3) Emergency or urgent care for patients who, due to the nature of their injury or illness, are incapable of taking action for self-preservation under emergency conditions without the assistance of others

**A.6.1.6.1** It is not the intent that occupants be considered to be incapable of self-preservation just because they are in a wheelchair or use assistive walking devices, such as a cane, a walker, or crutches. Rather, it is the intent to address emergency care centers that receive patients who have been rendered incapable of self-preservation due to the emergency, such as being rendered unconscious as a result of an accident or being unable to move due to sudden illness.

**6.1.6.2 Other. (Reserved)**

Exhibit 6.5 depicts an ambulatory health care occupancy.

Note that the definition of *ambulatory health care occupancy* in 6.1.6.1 stipulates an outpatient criterion, and that the definition of *health care occupancy* in 6.1.5.1 stipulates an inpatient criterion. A health care facility used only for outpatients is

Exhibit 6.4

A health care occupancy. (© Paul Brennan, Dreamstime.com)

Exhibit 6.5

An ambulatory health care occupancy. (© Mark Winfrey, Dreamstime.com)

addressed by 6.1.6.1 as an ambulatory health care occupancy and is subject to the provisions of Chapter 20 or Chapter 21. Health care occupancies, if they are to be protected by the provisions of Chapter 18 or Chapter 19, must have at least four inpatients. See 18.1.1.1.5, 18.1.1.1.9, 19.1.1.1.5, and 19.1.1.1.9 for criteria related to providing sleeping accommodations for more than 24 hours (i.e., the inpatient criterion).

Chapters 20 and 21 address the outpatient form of a health care occupancy. The requirements draw heavily from those applicable to business occupancies but supplement them with special provisions that address the fact that some patients in such occupancies are incapable of self-preservation. As is the case with other health care occupancies, the facility must accommodate at least four persons. The provisions of 6.1.6.1(1) through (3) further define the treatment, care, and initial condition of the patient that can render the patient incapable of self-preservation.

Dialysis treatment centers that accommodate four or more patients at one time generally fall under the classification of ambulatory health care occupancy based on 6.1.6.1(1). The blood-filtering treatment often wreaks havoc with the patients' blood pressure. Even if the patients are provided with instructions on how to clamp and cut their blood-filtering tubing, there is no assurance that they have the capability of immediately evacuating the facility without the assistance of others.

Day-surgery centers that accommodate four or more patients at one time generally fall under the classification of ambulatory health care occupancy based on 6.1.6.1(2). The anesthesia used prevents the patients from taking action for self-preservation under emergency conditions without the assistance of others.

Urgent-care centers that accommodate four or more patients at one time generally fall under the classification of ambulatory health care occupancy based on 6.1.6.1(3). The nature of the injury, illness, or condition present when patients arrive for treatment prevents patients from taking action for self-

preservation under emergency conditions without the assistance of others.

The four-person criterion of 6.1.6.1 is meant to be applied independently on an area-by-area basis within a building. For example, it is common practice for individual health care practitioners to rent their own tenant space within a multitenant office building. Assume three dentists, each specializing in tooth extraction where the patients are under general anesthesia, have their own tenant spaces. Each of the three dentists does not have more than two patients under anesthesia or recovering from the effects of anesthesia at any time. Although, collectively, the three dentists might have six patients simultaneously rendered incapable of self-preservation due to anesthesia, the four-person criterion is not satisfied within any tenant space considered alone. Each dentist's office would be considered a business occupancy and not an ambulatory health care occupancy.

**6.1.7 Detention and Correctional.** For requirements, see Chapters 22 and 23.

**6.1.7.1\* Definition — Detention and Correctional Occupancy.** An occupancy used to house one or more persons under varied degrees of restraint or security where such occupants are mostly incapable of self-preservation because of security measures not under the occupants' control.

**A.6.1.7.1** Detention and correctional occupancies include the following:

- (1) Adult and juvenile substance abuse centers
- (2) Adult and juvenile work camps
- (3) Adult community residential centers
- (4) Adult correctional institutions
- (5) Adult local detention facilities
- (6) Juvenile community residential centers
- (7) Juvenile detention facilities
- (8) Juvenile training schools

See A.22.1.1.1.6 and A.23.1.1.1.6.

**6.1.7.2\* Nonresidential Uses.** Within detention and correctional facilities, uses other than residential housing shall be in accordance with the appropriate chapter of the Code. (See 22.1.3.3 and 23.1.3.3.)

**A.6.1.7.2** Chapters 22 and 23 address the residential housing areas of the detention and correctional occupancy as defined in 3.3.190.5. Examples of uses, other than residential housing, include gymnasiums or industries.

Exhibit 6.6 depicts a detention and correctional occupancy.

The definition of *detention and correctional occupancy* (see 6.1.7.1) applies at the threshold of one or more persons. In editions of the Code prior to 2006, the threshold was four or more persons. This criterion for one person correlates with the provisions for lockups in other than detention and correctional occupancies, as addressed in 22.4.5 and 23.4.5, which were added to

Exhibit 6.6

A detention and correctional occupancy. (© Maigi, Dreamstime.com)

the *Code* in 2006. The provisions for lockups are needed for application even when only one person is detained, as the locked doors characteristic of such detention deny the occupant free egress as required by 7.2.1.5. A lockup in an occupancy other than detention and correctional that detains any individual for more than 24 hours is required to be classified as a detention and correctional occupancy (see 22.4.5.1.2 and 23.4.5.1.2) and is subject to the provisions of Chapter 22 or Chapter 23. Thus, the provisions of Chapters 22 and 23 needed to be made applicable to one or more residents.

Chapters 22 and 23 are intended to apply only to those areas of detention and correctional facilities used for occupant housing, such as sleeping and day activity areas. Other occupied spaces within the facility are to receive an occupancy classification representative of their use and are to be regulated by the applicable provisions of Chapters 12 through 21 and Chapters 24 through 42. For example, cafeterias are regulated using the assembly occupancy chapters, and metal shops follow the requirements of the industrial occupancy chapter. The authority having jurisdiction usually modifies the occupancy requirements of those chapters due to special security needs.

**6.1.8 Residential.** For requirements, see Chapters 24 through 31.

**6.1.8.1 Definition — Residential Occupancy.** An occupancy that provides sleeping accommodations for purposes other than health care or detention and correctional.

**6.1.8.1.1\* Definition — One- and Two-Family Dwelling Unit.** A building that contains not more than two dwelling units with independent cooking and bathroom facilities.

**A.6.1.8.1.1** The application statement of 24.1.1.1 limits each dwelling unit to being “occupied by members of a single family with not more than three outsiders.” The *Code* does not define the term *family*. The definition of family is subject to federal, state, and local regulations and might not be restricted to a person

or a couple (two people) and their children. The following examples aid in differentiating between a single-family dwelling and a lodging or rooming house:

- (1) An individual or a couple (two people) who rent a house from a landlord and then sublease space for up to three individuals should be considered a family renting to a maximum of three outsiders, and the house should be regulated as a single-family dwelling in accordance with Chapter 24.
- (2) A house rented from a landlord by an individual or a couple (two people) in which space is subleased to 4 or more individuals, but not more than 16, should be considered and regulated as a lodging or rooming house in accordance with Chapter 26.
- (3) A residential building that is occupied by 4 or more individuals, but not more than 16, each renting from a landlord, without separate cooking facilities, should be considered and regulated as a lodging or rooming house in accordance with Chapter 26.

Exhibit 6.7 depicts a one-family dwelling unit.

Exhibit 6.7

A one-family dwelling unit. (© Ligonography, Dreamstime.com)

**6.1.8.1.2 Definition — Lodging or Rooming House.** A building or portion thereof that does not qualify as a one- or two-family dwelling, that provides sleeping accommodations for a total of 16 or fewer people on a transient or permanent basis, without personal care services, with or without meals, but without separate cooking facilities for individual occupants.

Exhibit 6.8 depicts a lodging or rooming house.

**6.1.8.1.3\* Definition — Hotel.** A building or groups of buildings under the same management in which there are sleeping accommodations for more than 16 persons and primarily used by transients for lodging with or without meals.

Exhibit 6.8

A lodging or rooming house. (© Margiew, Dreamstime.com)

**A.6.1.8.1.3** So-called apartment hotels should be classified as hotels, because they are potentially subject to the same transient occupancy as hotels. Transients are those who occupy accommodations for less than 30 days.

Exhibit 6.9 depicts a hotel.

**6.1.8.1.4\* Definition — Dormitory.** A building or a space in a building in which group sleeping accommodations are provided for more than 16 persons who are not members of the same

Exhibit 6.9

A hotel. (© Arbaes, Dreamstime.com)

family in one room, or a series of closely associated rooms, under joint occupancy and single management, with or without meals, but without individual cooking facilities.

**A.6.1.8.1.4** Rooms within dormitories intended for the use of individuals for combined living and sleeping purposes are guest rooms or guest suites. Examples of dormitories include college dormitories, fraternity and sorority houses, and military barracks.

Exhibit 6.10 depicts a dormitory.

Exhibit 6.10

A dormitory. (© Arim44, Dreamstime.com)

**6.1.8.1.5 Definition — Apartment Building.** A building or portion thereof containing three or more dwelling units with independent cooking and bathroom facilities.

Exhibit 6.11 depicts an apartment building.

### 6.1.8.2 Other. (Reserved)

Residential occupancies are characterized by occupants who are asleep for a portion of the time they occupy the building. The sleeping that takes place is for normal restorative rest, as opposed to the sleeping that takes place in a hospital or residential board and care facility where caretakers are present. Sleeping occupants might be unaware of an incipient fire and might be trapped before egress can occur. This occupancy group is further divided into one- and two-family dwellings, lodging or rooming houses, hotels and dormitories, and apartment buildings. Each occupancy in the group has characteristic needs that differ from the others. For this reason, separate chapters of the *Code* address each of these subgroups or subclassifications.

The residential occupancy subclassifications of one- and two-family dwellings, lodging or rooming houses, hotels,

Exhibit 6.11

An apartment building. (© Tupungato, Dreamstime.com)

dormitories, and apartment buildings are defined in 6.1.8.1.1 through 6.1.8.1.5.

The definition of *apartment building* in 6.1.8.1.5 is copied from that in 3.3.36.3, which has advisory text in A.3.3.36.3. The text of A.3.3.36.3 clarifies that town house–type apartments — particularly those under condominium ownership — are to be classified as apartment buildings. It is often mistakenly believed that condominiums are a form of occupancy rather than a form of ownership.

Although people sleep in health care occupancies and detention and correctional occupancies, they occupy such facilities for other than normal residential purposes. Because the occupants of these facilities are incapable of self-preservation — in one case due to illness or infirmity and, in the other, as a result of security measures — the provisions that apply to normal residential occupancies might not provide the necessary level of life safety. The user is referred to Chapters 18 and 19 for inpatient health care occupancies and Chapters 22 and 23 for detention and correctional occupancies. See also 6.1.5 and 6.1.7.

**6.1.9 Residential Board and Care.** For requirements, see Chapters 32 and 33.

**6.1.9.1\* Definition — Residential Board and Care Occupancy.** An occupancy used for lodging and boarding of four or more residents, not related by blood or marriage to the owners or operators, for the purpose of providing personal care services.

**A.6.1.9.1** The following are examples of facilities classified as residential board and care occupancies:

- (1) Group housing arrangement for physically or mentally handicapped persons who normally attend school in the community, attend worship in the community, or otherwise use community facilities
- (2) Group housing arrangement for physically or mentally handicapped persons who are undergoing training in preparation for independent living, for paid employment, or for other normal community activities
- (3) Group housing arrangement for the elderly that provides personal care services but that does not provide nursing care
- (4) Facilities for social rehabilitation, alcoholism, drug abuse, or mental health problems that contain a group housing arrangement and that provide personal care services but do not provide acute care
- (5) Assisted living facilities
- (6) Other group housing arrangements that provide personal care services but not nursing care

**6.1.9.2 Other. (Reserved)**

Exhibit 6.12 depicts a residential board and care occupancy.

Residential board and care occupancies, as in the case of residential occupancies, provide sleeping accommodations. However, the residents also receive personal care services by caretakers who live with the residents. Personal care includes assistance with many of the activities of daily living, such as bathing and dressing. Personal care does not include medical care.

The provision of personal care services to residents of residential board and care facilities is an indicator that the residents might have special needs. The requirements of Chapters 32 and 33 credit the combined abilities of staff and residents, working together, to evacuate the building or relocate to a point of safety.

Exhibit 6.12

A residential board and care occupancy. (© Jennifer Walz, Dreamstime.com)

**6.1.10 Mercantile.** For requirements, see [Chapters 36](#) and [37](#).

**6.1.10.1\* Definition — Mercantile Occupancy.** An occupancy used for the display and sale of merchandise.

**A.6.1.10.1** Mercantile occupancies include the following:

- (1) Auction rooms
- (2) Department stores
- (3) Drugstores
- (4) Restaurants with fewer than 50 persons
- (5) Shopping centers
- (6) Supermarkets

Office, storage, and service facilities incidental to the sale of merchandise and located in the same building should be considered part of the mercantile occupancy classification.

**6.1.10.2 Other. (Reserved)**

[Exhibit 6.13](#) depicts a mercantile occupancy.

Mercantile occupancies, as in the case of assembly occupancies, are characterized by large numbers of people who gather in a space that is relatively unfamiliar to them. In addition, mercantile occupancies often contain sizable quantities of combustible contents and use circuitous egress paths that are deliberately arranged to force occupants to travel around displays of materials that are available for sale.

Mall buildings, while predominantly occupied by mercantile occupancies, typically have assembly occupancies within

**Exhibit 6.13**

A mercantile occupancy. (© Michael Ludwig, [Dreamstime.com](#))

them (e.g., food courts or cinemas), which classifies the mall building as a multiple occupancy building. In [12.1.3.4](#) and [13.1.3.4](#), applicable to new and existing assembly occupancies, the provisions of [Chapters 12](#) and [13](#) are made applicable to the assembly occupancy tenant space, but the specialized mall criteria of [36.4.4](#) and [37.4.4](#) from the mercantile occupancy chapters are made applicable to the space outside the assembly occupancy tenant space, as that space might be used for egress by the occupants of the assembly occupancy.

Bulk merchandising retail buildings, which characteristically consist of a warehouse-type building occupied for sales purposes, are a subclass of mercantile occupancy with a greater potential for hazards than more traditional mercantile operations. See also [36.4.5](#) and [37.4.5](#).

**6.1.11 Business.** For requirements, see [Chapters 38](#) and [39](#).

**6.1.11.1\* Definition — Business Occupancy.** An occupancy used for the transaction of business other than mercantile.

**A.6.1.11.1** Business occupancies include the following:

- (1) Air traffic control towers (ATCTs)
- (2) City halls
- (3) College and university instructional buildings, classrooms under 50 persons, and instructional laboratories
- (4) Courthouses
- (5) Dentists' offices
- (6) Doctors' offices
- (7) General offices
- (8) Outpatient clinics (ambulatory)
- (9) Town halls

Doctors' and dentists' offices are included, unless of such character as to be classified as ambulatory health care occupancies. (See [3.3.190.1](#).)

Birth centers should be classified as business occupancies if they are occupied by fewer than four patients, not including infants, at any one time; do not provide sleeping facilities for four or more occupants; and do not provide treatment procedures that render four or more patients, not including infants, incapable of self-preservation at any one time. For birth centers occupied by patients not meeting these parameters, see [Chapter 18](#) or [Chapter 19](#), as appropriate.

Service facilities common to city office buildings, such as newsstands, lunch counters serving fewer than 50 persons, barber shops, and beauty parlors are included in the business occupancy group.

City halls, town halls, and courthouses are included in this occupancy group, insofar as their principal function is the transaction of public business and the keeping of books and records. Insofar as they are used for assembly purposes, they are classified as assembly occupancies.

**6.1.11.2 Other. (Reserved)**

[Exhibit 6.14](#) depicts a business occupancy.

**Exhibit 6.14**

A business occupancy. (© Brianguest, Dreamstime.com)

Business occupancies generally have a lower occupant density than mercantile occupancies, and the occupants are usually more familiar with their surroundings. However, confusing and indirect egress paths are often developed due to office layouts and the arrangement of tenant spaces. The *Code* requirements for such occupancies address the needs of visitors unfamiliar with the building.

Depending on the characteristics of a laboratory, it may be classified as a business occupancy, industrial occupancy, or other occupancy.

Paragraph A.6.1.11.1 provides guidance in classifying a birth center as a business occupancy or a health care occupancy. The definition of *birth center* appears in 3.3.33. Also see A.3.3.33, Birth Center.

A medical office that provides treatment or performs procedures that render patients incapable of self-preservation might be classified as an ambulatory health care occupancy or as a business occupancy. Guidance on the subject appears in the commentary that follows 6.1.6.2.

**6.1.12 Industrial.** For requirements, see Chapter 40.

**6.1.12.1\* Definition — Industrial Occupancy.** An occupancy in which products are manufactured or in which processing, assembling, mixing, packaging, finishing, decorating, or repair operations are conducted.

**A.6.1.12.1** Industrial occupancies include the following:

- (1) Drycleaning plants
- (2) Factories of all kinds
- (3) Food processing plants
- (4) Gas plants
- (5) Hangars (for servicing/maintenance)
- (6) Laundries
- (7) Power plants
- (8) Pumping stations

- (9) Refineries
- (10) Sawmills
- (11) Telephone exchanges

In evaluating the appropriate classification of laboratories, the authority having jurisdiction should treat each case individually, based on the extent and nature of the associated hazards. Some laboratories are classified as occupancies other than industrial; for example, a physical therapy laboratory or a computer laboratory.

#### 6.1.12.2 Other. (Reserved)

Exhibit 6.15 depicts an industrial occupancy.

**Exhibit 6.15**

An industrial occupancy. (© Typhoonski, Dreamstime.com)

Industrial occupancies expose occupants to a wide range of processes and materials of varying hazard. Special-purpose industrial occupancies, which are characterized by large installations of equipment that dominate the space, are addressed separately from general-purpose industrial facilities, which have higher densities of human occupancy.

Industrial occupancy buildings, along with storage occupancy buildings, are more likely than any other occupancy to have contents with a wide range of hazards. Where industrial operations in a special-purpose industrial occupancy or general-purpose industrial occupancy include high hazard materials, processes, or contents (see 6.2.2.4), the occupancy is to be classified as a high hazard industrial occupancy, not as a special-purpose or general-purpose industrial occupancy.

Depending on the characteristics of a laboratory, it may be classified as a business occupancy, industrial occupancy, or other occupancy.

**6.1.13 Storage.** For requirements, see Chapter 42.

**6.1.13.1\* Definition — Storage Occupancy.** An occupancy used primarily for the storage or sheltering of goods, merchandise, products, or vehicles.

**A.6.1.13.1** Storage occupancies include the following:

- (1) Barns
- (2) Bulk oil storage
- (3) Cold storage
- (4) Freight terminals
- (5) Grain elevators
- (6) Hangars (for storage only)
- (7) Parking structures
- (8) Truck and marine terminals
- (9) Warehouses

Storage occupancies are characterized by the presence of relatively small numbers of persons in proportion to the area.

**6.1.13.2 Other. (Reserved)**

Exhibit 6.16 depicts a storage occupancy.

**Exhibit 6.16**

A storage occupancy. (© Pemmett, Dreamstime.com)

Storage occupancies are characterized by relatively low human occupancy in comparison to building size and by varied hazards associated with the materials stored.

Storage occupancy buildings, along with industrial occupancy buildings, are more likely than any other type of occupancy to have contents with a wide range of hazards.

Bulk merchandising retail buildings, which characteristically consist of a warehouse-type building, occupied for sales purposes, are a subclass of mercantile occupancy rather than a storage occupancy. See 36.4.5 and 37.4.5.

In *Code* editions prior to 2009, the sheltering of animals was one of the examples of a storage occupancy included in the

definition of *storage occupancy*. The phrase “sheltering of animals” was deleted, as not all facilities housing animals are storage occupancies. See NFPA 150, *Standard on Fire and Life Safety in Animal Housing Facilities*.<sup>1</sup>

**6.1.14 Multiple Occupancies.**

**6.1.14.1 General.**

**6.1.14.1.1** Multiple occupancies shall comply with the requirements of 6.1.14.1 and one of the following:

- (1) Mixed occupancies — 6.1.14.3
- (2) Separated occupancies — 6.1.14.4

Classifying a building simply as a multiple occupancy is an incomplete classification, as the options for occupancy classification are limited to assembly, educational, day-care, health care, ambulatory health care, detention and correctional, residential (one- and two-family dwellings, lodging or rooming houses, hotels and dormitories, or apartment buildings), residential board and care, mercantile, business, industrial, and storage. Rather, a classification of multiple occupancy needs to include mention of the occupancy types involved. For example, a multiple occupancy building with spaces used for sales and spaces used for storage should be classified as a multiple occupancy that is part mercantile occupancy and part storage occupancy.

Once a building is classified as a multiple occupancy and the occupancy types present are identified, the provisions of 6.1.14.1.1 are applied. Paragraph 6.1.14.1.1 offers the option of protecting multiple occupancies via the mixed occupancies requirements of 6.1.14.3 or via the separated occupancies requirements of 6.1.14.4.

If the mixed occupancies option of 6.1.14.3 is chosen for the protection of the multiple occupancy, the *Code* provisions for all occupancy types present must be compared. For each subject area addressed, the more stringent requirement from the applicable occupancy chapters must be identified and followed. Consider, for example, a new multiple occupancy building that is part ordinary hazard mercantile occupancy and part ordinary hazard storage occupancy for which the mixed occupancies form of protection is to be provided. In comparing the requirements of Chapter 36 for new mercantile occupancies and Chapter 42 for ordinary hazard storage occupancies, it becomes evident that neither occupancy is consistently stricter than the other on all features and systems addressed by the occupancy chapter. For example, both occupancies are permitted to use access-controlled egress doors in accordance with 7.2.1.6.2, but mercantile occupancies are permitted to do so only if the entire building is protected throughout by either a fire detection system or a sprinkler system (see 36.2.2.2.6 and 42.2.2.2.3). Mercantile occupancies are permitted to use horizontal or vertical security grilles or doors in accordance with 7.2.1.4.1(3) as part of the means of egress from a tenant space (see 36.2.2.2.7), but no such permission is given for storage occupancies in 42.2.2.2. In each case, the more stringent provision must be followed in the multiple occupancy being protected as a mixed occupancy.

If the separated occupancies option of 6.1.14.4 is chosen for the protection of the multiple occupancy, the Code user must identify the appropriate cell or cells of Table 6.1.14.4.1(a) or Table 6.1.14.4.1(b) to determine the minimum hourly fire resistance rating needed for the barriers separating the occupancies from each other.

**6.1.14.1.2** Where exit access from an occupancy traverses another occupancy, the multiple occupancy shall be treated as a mixed occupancy.

Paragraph 6.1.14.1.2 was new to the 2006 edition of the Code. It was added to clarify the original intent, which was not fully explained when the provisions for multiple occupancies were added to the 2003 edition. Users incorrectly believed they could satisfy the provisions for multiple occupancies protected as separated occupancies by complying with the following two-step approach:

1. Separate the multiple occupancies from each other by the fire resistance-rated construction required by Table 6.1.14.4.1(a) or Table 6.1.14.4.1(b).
2. Provide egress paths from one of the occupancies to involve travel through doors in the separating construction into the other occupancy (meaning that the two occupancies would share exit access, for example in a common corridor). See Exhibit 6.17.

Multiple occupancy building with shared exit access corridor, which prohibits it from protection via the separated occupancies provisions.

The shared exit access corridor system does not permit the multiple occupancy to be protected as separated occupancies. Instead, the multiple occupancy must be protected as mixed occupancies.

In Exhibit 6.18, the two required means of egress for the business occupancy are provided by two remotely located doors opening directly to the outside. The door openings to the corridor, located in the fire resistance-rated occupancy separation barrier, are convenient extras not required by the Code. With this arrangement, the multiple occupancy is permitted to be protected as separated occupancies.

**6.1.14.1.3\*** Where incidental to another occupancy, areas used as follows shall be permitted to be considered part of the predominant occupancy and shall be subject to the provisions of the Code that apply to the predominant occupancy:

- (1) Mercantile, business, industrial, or storage use
- (2)\* Nonresidential use with an occupant load fewer than that established by Section 6.1 for the occupancy threshold

**A.6.1.14.1.3** Examples of uses that might be incidental to another occupancy include the following:

- (1) Newsstand (mercantile) in an office building
- (2) Giftshop (mercantile) in a hotel
- (3) Small storage area (storage) in any occupancy

Multiple occupancy building permitted to be protected via the separated occupancies provisions.

- (4) Minor office space (business) in any occupancy
- (5) Maintenance area (industrial) in any occupancy

**A.6.1.14.1.3(2)** Examples of uses that have occupant loads below the occupancy classification threshold levels include the following:

- (1) Assembly use with fewer than 50 persons within a business occupancy
- (2) Educational use with fewer than 6 persons within an apartment building.

**Paragraph 6.1.14.1.3** clarifies that some, but not all, incidental uses can be considered part of the predominant occupancy. Incidental residential uses, regardless of the number of persons for whom sleeping accommodations are provided, are classified as residential occupancies and are subject to the appropriate residential occupancy chapter requirements. For example, if there are sleeping facilities for five fire fighters in a fire station, the *Code* does not permit the building to be classified simply as a storage occupancy where motor vehicles are sheltered. Rather, the proper classification is a multiple occupancy that is part storage occupancy and part residential occupancy (i.e., lodging or rooming house in this case). The requirements that apply to both occupancies need to be compared, with the more stringent provisions applied in accordance with 6.1.14.3, or the occupancies need to be separated from each other by fire resistance-rated construction in accordance with 6.1.14.4, in which case each occupancy is prohibited from sharing the other occupancy's means of egress per 6.1.14.1.2.

In addition, a day-care use with more than 3 clients is not exempted by either of the criteria of 6.1.14.1.3. For example, a small day-care center with 14 clients located in a high-rise office building is not part of the predominant business occupancy. The more stringent of the requirements that apply to day-care occupancies and business occupancies need to be implemented in accordance with 6.1.14.3, or the occupancies need to be separated from each other by fire resistance-rated construction in accordance with 6.1.14.4, in which case each occupancy is prohibited from sharing the other occupancy's means of egress per 6.1.14.1.2.

If the day-care use in the high-rise office building addressed in the preceding paragraph had only 3 clients, that number of clients would be less than the threshold number of 4 clients at which a day-care use becomes a day-care occupancy (see 6.1.4.1). The day-care use could, therefore, be classified as incidental to the business occupancy as permitted by 6.1.14.1.3(2).

### 6.1.14.2 Definitions.

**6.1.14.2.1 Multiple Occupancy.** A building or structure in which two or more classes of occupancy exist.

**6.1.14.2.2 Mixed Occupancy.** A multiple occupancy where the occupancies are intermingled.

**6.1.14.2.3 Separated Occupancy.** A multiple occupancy where the occupancies are separated by fire resistance-rated assemblies.

### 6.1.14.3 Mixed Occupancies.

**6.1.14.3.1** Each portion of the building shall be classified as to its use in accordance with Section 6.1.

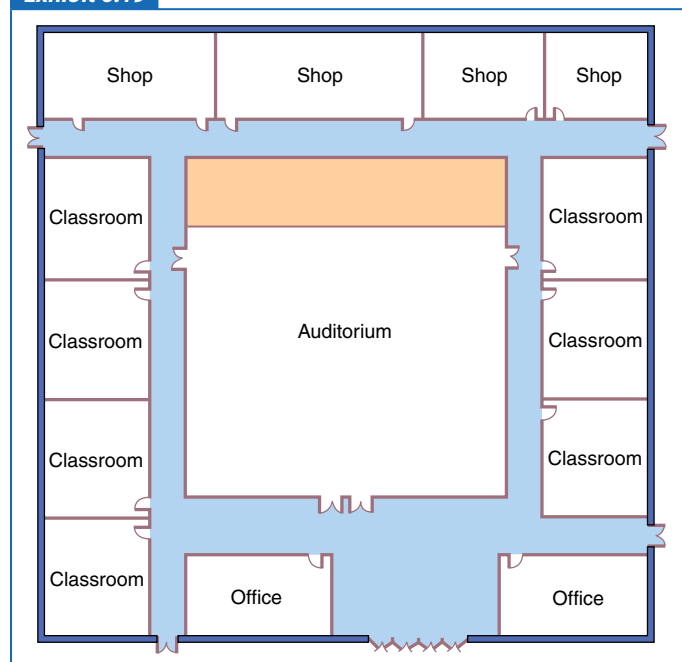

**6.1.14.3.2\*** The building shall comply with the most restrictive requirements of the occupancies involved, unless separate safeguards are approved.

**A.6.1.14.3.2** For example, a common path of travel that occurs wholly in a business tenant space, in a multiple occupancy building containing assembly and business occupancies, should not have to meet the assembly occupancy common path of travel limitation.

An example of a multiple occupancy building that is protected as a mixed occupancy is illustrated in Exhibit 6.19. Because the assembly occupancy (i.e., the auditorium) shares the internal corridor egress system with the educational occupancy classrooms and shops, separating the individual occupancies from each other so that they do not share any common exit access is impractical. Therefore, the provision of 6.1.14.1.2 requires that the multiple occupancy be protected as mixed occupancies.

In the building depicted in Exhibit 6.19, assume that the office space (business occupancy) is considered incidental to the predominant occupancies of educational (i.e., the classrooms and shops) and assembly (i.e., the auditorium) as permitted by 6.1.14.1.3(1). Assuming also that the building is new, the occupancy requirements of Chapter 12 for new assembly occupancies are compared with those of Chapter 14 for new educational occupancies for each of the subjects addressed by the *Code*. In

**Exhibit 6.19**

*Multiple occupancy building protected via the mixed occupancies provisions.*

each comparison of requirements between the applicable occupancy chapters, the more stringent requirement is chosen as having applicability to the multiple occupancy.

For example, the 6 ft (1830 mm) minimum corridor width requirement of 14.2.3.2 for educational occupancies is stricter than the 44 in. (1120 mm) minimum requirement of 12.2.3.8 for assembly occupancies and, thus, applies throughout the floor. The panic hardware requirement of 12.2.2.2.3 for assembly occupancies is identical to that in 14.2.2.2.2 for educational occupancies; therefore, this common requirement applies to all doors provided with latches or locks throughout the multiple occupancy. With regard to travel distance, in assembly occupancies, travel distance to the nearest exit is limited by 12.2.6.2 to a maximum of 200 ft (61 m) in a nonsprinklered building or 250 ft (76 m) in a sprinklered building; educational occupancies are limited by 14.2.6.2 and 14.2.6.3 to a 150 ft (46 m) travel distance in a nonsprinklered building and 200 ft (61 m) in a sprinklered building. So, the stricter travel distance requirement from the educational occupancy chapter applies to the multiple occupancy.

Paragraph 6.1.14.3.2 was revised, and the advisory text of A.6.1.14.3.2 was added for the 2012 edition of the Code. The revision reinstates a concept that was lost when the provisions for multiple occupancy buildings were rewritten for the 2003 edition. Where separate safeguards are approved (see 3.2.1), one or more applicable Code requirements are permitted to be relaxed to that provision applicable to the occupancy in question, rather than mandating use of the most restrictive requirement of the occupancies involved. The annex text provides a good example of the application of the exemption permitted by the words “unless separate safeguards are approved” in 6.1.14.3.2.

#### 6.1.14.4 Separated Occupancies. (See also 6.1.14.1.2.)

**6.1.14.4.1** Where separated occupancies are provided, each part of the building comprising a distinct occupancy, as described in this chapter, shall be completely separated from other occupancies by fire-resistive assemblies, as specified in 6.1.14.4.2, 6.1.14.4.3, Table 6.1.14.4.1(a), and Table 6.1.14.4.1(b), unless separation is provided by approved existing separations or as otherwise permitted by 6.1.14.4.6.

**6.1.14.4.2** Occupancy separations shall be classified as 3-hour fire resistance-rated, 2-hour fire resistance-rated, or 1-hour fire resistance-rated and shall meet the requirements of Chapter 8.

**6.1.14.4.3** The minimum fire resistance rating specified in Table 6.1.14.4.1(a) and Table 6.1.14.4.1(b) shall be permitted to be reduced by 1 hour, but in no case shall it be reduced to less than 1 hour, where the building is protected throughout by an approved automatic sprinkler system in accordance with 9.7.1.1(1) and supervised in accordance with 9.7.2, unless prohibited by the double-dagger footnote entries in the tables.

**6.1.14.4.4** Occupancy separations shall be vertical, horizontal, or both or, when necessary, of such other form as required to provide complete separation between occupancy divisions in the building.

**6.1.14.4.5\*** Each separated portion of the building shall comply with the requirements for the occupancy therein.

**A.6.1.14.4.5** Where the Code text states that the provision has applicability to the building, rather than just to the occupancy, the provision applies to the entire building, regardless of whether the separated occupancies form of protection is used. For example, the provision of 18.3.5.1 requires that the entire building housing a health care occupancy be sprinklered. Contrast that with the requirement of 20.3.4.1, which requires an ambulatory health care facility, and not the entire building, to be provided with a fire alarm system.

**6.1.14.4.6** Where permitted in Chapters 11 through 43, atrium walls shall be permitted to serve as part of the separation required by 6.1.14.4.1 for creating separated occupancies on a story-by-story basis, provided all of the following are met:

- (1) The atrium is separated from adjacent areas by walls that are smoke partitions in accordance with Section 8.4.
- (2) Doors in the smoke partitions required by 6.1.14.4.6(a) are equipped with positive latching hardware.
- (3) The atrium meets the provisions of 8.6.7 that are applicable to new atriums.

Note that 6.1.14.4.1 requires the fire-rated construction separating occupancies protected as separated occupancies to have the minimum fire resistance rating specified in Table 6.1.14.4.1(a) and Table 6.1.14.4.1(b), unless separation is provided by approved existing separations. The phrase “unless separation is provided by approved existing separations” does not mean that existing separations are exempt from the requirements of Table 6.1.14.4.1(a) and Table 6.1.14.4.1(b). An approved existing separation is a separation approved by the current authority having jurisdiction and is different from a previously approved separation. See 3.3.81.1 for the definition of the term *approved existing* and 3.3.214 for the definition of the term *previously approved*. If the current AHJ refuses to approve an existing separation, the provisions of Table 6.1.14.4.1(a) and Table 6.1.14.4.1(b) can be invoked, as applicable. For example, where an existing separation stops at the underside of a suspended ceiling, the AHJ can withhold approval of the existing separation and require compliance with Table 6.1.14.4.1(a) and Table 6.1.14.4.1(b). In another example, the existing separation in a sprinklered building is judged to have approximately 45 minutes of fire resistance rating, but Table 6.1.14.4.1(a) and Table 6.1.14.4.1(b) require a minimum 1-hour rating in such a building. The AHJ judges the existing separation acceptable and approves it. The existing separation becomes an approved existing separation not subject to the requirements of Table 6.1.14.4.1(a) and Table 6.1.14.4.1(b).

Exhibit 6.20 illustrates a simple example of a multiple occupancy building where the individual occupancies can easily be protected as separated occupancies. Because each individual-use space is arranged to meet its egress requirements independently of its neighbors, meeting only the requirements that apply to the occupancy of that individual-use space (see

Table 6.1.14.4.1(a) Required Separation of Occupancies (hours),<sup>†</sup> Part 1

Occupancy	Assembly ≤300	Assembly >300 to ≤1000	Assembly >1000	Educational	Day-Care >12 Clients	Day-Care Homes	Health Care	Ambulatory Health Care	Detention & Correctional	One- & Two-Family Dwellings	Lodging or Rooming Houses	Hotels & Dormitories

NP: Not permitted.

<sup>†</sup>Minimum Fire Resistance Rating. The fire resistance rating is permitted to be reduced by 1 hour, but in no case to less than 1 hour, where the building is protected throughout by an approved automatic sprinkler system in accordance with 9.7.1.1(1) and supervised in accordance with 9.7.2.

<sup>‡</sup>The 1-hour reduction due to the presence of sprinklers in accordance with the single-dagger footnote is not permitted.

Multiple occupancy building protected via the separated occupancies provisions.

6.1.14.4.5) is adequate to protect each space if the fire resistance-rated separations required by Table 6.1.14.4.1(a) or Table 6.1.14.4.1(b) are provided.

Table 6.1.14.4.1(a) and Table 6.1.14.4.1(b) were editorially expanded for the 2012 edition of the Code. The expansion of the tables was made to ensure that the Code user finds the required fire resistance rating, regardless of the order (i.e., reading down the left column for locating one of the occupancies and reading horizontally across the top columns of the table for locating the other occupancy) in which the affected occupancies are accessed

**Table 6.1.14.4.1(b) Required Separation of Occupancies (hours)<sup>†</sup>, Part 2**

NP: Not permitted.

<sup>†</sup>*Minimum Fire Resistance Rating.* The fire resistance rating is permitted to be reduced by 1 hour, but in no case to less than 1 hour, where the building is protected throughout by an approved automatic sprinkler system in accordance with 9.7.1.1(1) and supervised in accordance with 9.7.2.

<sup>‡</sup>The 1-hour reduction due to the presence of sprinklers in accordance with the single-dagger footnote is not permitted.

in the table. For example, in earlier editions, if the table was used to locate the required separation between business and mercantile occupancies, and the user located business occupancies in the left column and mercantile occupancies by reading across the horizontal columns, the intersecting cell in the table was blank. The user was expected to reverse the locating procedure and locate mercantile occupancies in the left column; locate business occupancies in the columns at the top of the table; and then note the required fire separation in the intersecting cell. The editorial expansion of the table ensures the user can locate the required fire separation in a single step.

In the case of a multiple occupancy that is part mercantile occupancy and part business occupancy, the corresponding cell in Table 6.1.14.4.1(b) specifies that a 2-hour fire resistance-rated separation is required to achieve protection of the multiple occupancy as separated occupancies if the building is not sprinklered. If the multiple occupancy building is sprinklered and the sprinkler system is electrically supervised, the 2-hour fire resistance-rated separation is permitted to be reduced to 1 hour per the dagger symbol footnote to Table 6.1.14.4.1(b) and its reference to the sprinkler system supervision requirements of 9.7.2.

The provision of 6.1.14.4.6 is new to the 2015 edition of the Code. It recognizes an atrium as part of the separation required for protecting multiple occupancies as separated occupancies, but only where an occupancy chapter specifically permits its use. For example, health care occupancies permit the use of 6.1.14.4.6 in 18.1.3.2 and 19.1.3.2. Further, 6.1.14.4.6 permits the atrium to serve as part of the separation of occupancies only on a story-by-story basis. This concept is explained in the following paragraphs.

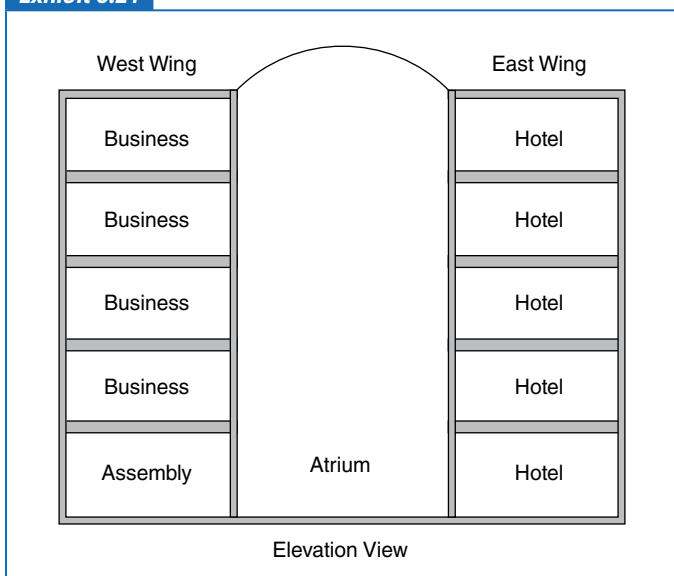

Exhibit 6.21 illustrates a multiple occupancy building, with an atrium, under design. The West wing will include assembly occupancy on floor 1 and business occupancy on floors 2 through 4. The East wing will be hotel occupancy on floors 1 through 4. The building (i.e., the combination of the West wing, atrium, and East wing) will be protected throughout by approved sprinkler systems in accordance with 9.7.1.1(1) that are supervised in accordance with 9.7.2. For purposes of simplifying this example, the atrium will be an indoor garden with occupants relegated only to the paths connecting the West and East wings. The atrium will fully comply with the requirements of 8.6.7 that are applicable to new atriums, meaning that the atrium will have a smoke control system for compliance with the performance criteria of 8.6.7(5).

The multiple occupancy building illustrated in Exhibit 6.21 could be protected as mixed occupancies in accordance with 6.1.14.1.1(1) or as separated occupancies in accordance with 6.1.14.1.1(2). The building designer, on behalf of the owner, has chosen to protect the multiple occupancy building as separated occupancies. Further, the designer has chosen to utilize the provision of 6.1.14.4.6 as permitted by 12.1.3.2 for assembly

occupancies and by 38.1.3.3 for business occupancies. As a point of interesting, but unneeded, information — as addressed below — the hotel occupancy provisions of 28.1.3.3 also permit the use of 6.1.14.4.6. Occupants of each occupancy will have access to their required exits without using the exit access paths of any other occupancy (see 6.1.14.1.2). The required separation between each occupancy is a 1-hour fire resistance-rated barrier based on the presence of sprinkler protection as detailed in the daggered footnote to Table 6.1.14.4.1(a) or Table 6.1.14.4.1(b).

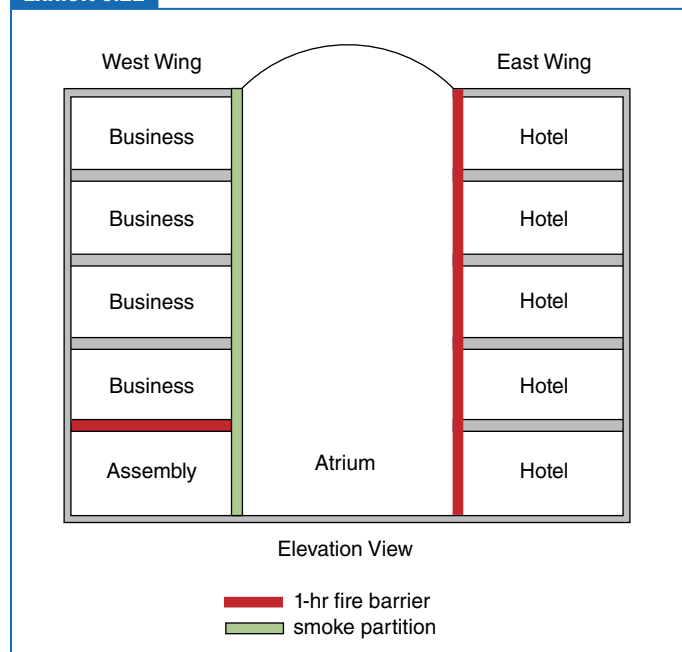

Exhibit 6.22 illustrates that the required separation between the assembly occupancy on floor 1 and the business occupancy on floors 2 through 4 of the West wing will be provided by the combination of the 1-hour fire resistance-rated floor-ceiling assembly and the smoke partition comprising the West wall of the atrium as shown in the exhibit. Given that 6.1.14.4.6 permits the atrium wall to serve as part of an occupancy separation only on a floor-by-floor basis, the hotel occupancy in the East wing can meet its required separation from the West wing only via the traditional, side-by-side arrangement. It achieves the separation from the West wing by making the East wall of the atrium a 1-hour fire resistance-rated wall assembly. Note that the smoke partition at the atrium West wall serves only as part of an occupancy separation in conjunction with a floor-ceiling assembly, whereas the fire-rated atrium East wall serves, by itself, as an occupancy separation.

Exhibit 6.21

Multiple occupancy building with atrium.

Exhibit 6.22

Multiple occupancy building utilizing atrium walls in occupancy separations.

### Combining the Mixed Occupancies and Separated Occupancies Forms of Protection

The commentary and [Exhibit 6.19](#) that follow [6.1.14.3.2](#) address the mixed occupancies form of protection. The commentary and [Exhibits 6.20](#) through [6.22](#) that follow [6.1.14.4.6](#) address the separated occupancies form of protection. In multiple occupancy buildings with three or more occupancies present, it is not the intent of [6.1.14.1.1](#) to require all the occupancies to be protected by one common scheme, whether the scheme be that for mixed occupancies or that for separated occupancies. In other words, it is possible for a portion of a multiple occupancy building to be protected as a mixed occupancy and for another portion of the same multiple occupancy building to be separated from the mixed occupancies by fire-rated barriers as required by [Table 6.1.14.4.1\(a\)](#) or [Table 6.1.14.4.1\(b\)](#) so as to be considered a separated occupancy.

In [Exhibit 6.23](#), assume that (1) the building is new; (2) the building is protected throughout by an approved automatic sprinkler system in accordance with [9.7.1.1\(1\)](#) and supervised in accordance with [9.7.2](#); (3) the office space (business occupancy) is considered incidental to the predominant occupancies of educational (i.e., the classrooms), assembly (i.e., the auditorium, which, in this case, has an occupant load exceeding 300), and day-care, as permitted by [6.1.14.1.3\(1\)](#). The day-care occupancy space satisfies all required egress features via the two sets of doors that discharge directly outside; the doors from the day-care space to the corridor are convenience doors provided in excess of *Code* requirements. The day-care occupancy space is separated from the combined assembly occupancy and educational occupancy spaces by 1-hour fire resistance-rated construction in compliance with [Table 6.1.14.4.1\(a\)](#) so as to meet the separated occupancies form of protection. [Table 6.1.14.4.1\(a\)](#) was used to establish the minimum 1-hour fire-rated separation as follows:

1. In the first column, in the row for assembly >300 to ≤1000, the user moves across the table to the column for day-care >12 clients, noting the required fire rating of 2 hours.
2. In the first column, in the row for educational, the user moves across the table to the column for day-care >12 clients, noting the required fire rating of 2 hours.
3. In the title of [Table 6.1.14.4.1\(a\)](#), the user notes the superscript dagger symbol and references the corresponding footnote. The building is protected throughout by an approved automatic sprinkler system in accordance with [9.7.1.1\(1\)](#) and supervised in accordance with [9.7.2](#), so the required fire-rated separation values of 2 hours from the applicable table cells are reduced to 1 hour.

Returning to [Exhibit 6.23](#), the assembly occupancy space, which is landlocked at the center of the building, shares its exit access with that of the educational occupancy spaces. The provision of [6.1.14.1.2](#) requires that the portion of the multiple

**Exhibit 6.23**

*Multiple occupancy building protected via combination of the mixed occupancies and separated occupancies provisions.*

occupancy building that houses the assembly occupancy and the educational occupancy be protected as mixed occupancies. The occupancy requirements of [Chapter 12](#) for new assembly occupancies are compared with those of [Chapter 14](#) for new educational occupancies for each of the subjects addressed by the *Code*. In each comparison of requirements between the applicable occupancy chapters, the more stringent requirement is chosen as having applicability to the portion of the multiple occupancy building housing the assembly occupancy and educational occupancy spaces being protected as mixed occupancies, unless separate safeguards are approved (see [6.1.14.3.2](#) and the example in [A.6.1.14.3.2](#)).

## 6.2 Hazard of Contents

### 6.2.1 General.

**6.2.1.1** For the purpose of this *Code*, the hazard of contents shall be the relative danger of the start and spread of fire, the danger of smoke or gases generated, and the danger of explosion or other occurrence potentially endangering the lives and safety of the occupants of the building or structure.

The classification of hazard of contents is based on the potential threat to life presented by the contents. A fuel load that might be considered as *light hazard* contents in terms of its ease of

extinguishment by a sprinkler system might, in fact, produce enough smoke and other products of combustion to threaten the lives of the occupants. In this case, the provision of [Section 6.2](#) leads the user to classifying the material as *ordinary hazard contents*.

The *Code's* method of classifying hazard of contents is based on life safety. For this reason, the *Code's* provisions are not readily incorporated into the design criteria of other codes or standards where hazard classification is based on property preservation. Many light hazard materials, in terms of extinguishment characteristics, are required to be treated as ordinary hazard under the *Code*. For example, a business occupancy might be classified as light hazard contents by NFPA 13, *Standard for the Installation of Sprinkler Systems*,<sup>2</sup> for purposes of sprinkler system design but be considered ordinary hazard contents for purposes of applying *Life Safety Code* requirements.

The *Life Safety Code* classifies contents based on the threat of fire, explosions, and other similar events. It generally does not specifically consider the danger posed by toxic chemicals, etiologic contamination, or similar hazards. However, the new provision of [42.1.5.2](#) for storage occupancies requires that hazardous materials that exceed the maximum allowable quantities (MAQs) as permitted in the fire code be classified as high hazard contents. It is expected that future editions of the *Code* will address hazardous materials in greater detail, as the Correlating Committee on Safety to Life has charged the life safety technical committees with studying the subject.

**6.2.1.2** Hazard of contents shall be classified by the registered design professional (RDP) or owner and submitted to the authority having jurisdiction for review and approval on the basis of the character of the contents and the processes or operations conducted in the building or structure.

The provision of [6.2.1.2](#) places the task of tentatively determining the hazard of contents on the building owner or registered design professional (RDP). The authority having jurisdiction then receives the owner's or RDP's recommended classification, reviews it on the basis of the character of the contents and operations present, and either approves or disapproves such classification. In most cases, a tentative classification of ordinary hazard contents will receive the AHJ's approval. In cases where there is nothing combustible, a safe classification is that of light hazard contents, but the contents of few spaces are limited to such materials. Where rapid fire spread is expected or there is potential for explosion, the logical tentative classification for presentation to the AHJ is that of high hazard contents.

**6.2.1.3\*** For the purpose of this *Code*, where different degrees of hazard of contents exist in different parts of a building or structure, the most hazardous shall govern the classification, unless hazardous areas are separated or protected as specified in [Section 8.7](#) and the applicable sections of [Chapters 11](#) through [43](#).

**A.6.2.1.3** Under the provision of [6.2.1.3](#), any violation of the requirements of [Chapters 11](#) through [42](#) for separation or protection of hazardous operation or storage would inherently involve violation of the other sections of the *Code*, unless additional egress facilities appropriate to high hazard contents were provided.

The presence of a high hazard contents area on a floor does not have to result in classification of the entire floor as a high hazard contents area if separation or protection is provided in accordance with the requirements of [Section 8.7](#). Once the potential hazard has been mitigated either by automatic sprinkler protection or via isolation from the remainder of the floor by fire resistance-rated construction, the remainder of the floor, if it has ordinary hazard contents, is permitted to be treated as an ordinary hazard contents area. For example, in an industrial occupancy where an area is used for the dispensing and transfer of flammable liquids from large containers to smaller containers, and such area is separated by fire resistance-rated construction in accordance with [Section 8.7](#), the requirements for high hazard contents areas apply only within the high hazard contents area. The remainder of the floor is not penalized by the presence of the high hazard contents area, provided that the requisite separation is present. For details on the limitations imposed on areas having high hazard contents — such as maximum 75 ft (23 m) travel distance needed for occupants to get out of the immediate high hazard space — see [Section 7.11](#).

[Paragraph 6.2.1.3](#) references the separation or protection provisions of [Section 8.7](#), as do the requirements of the [\\_\\_.3.2](#) subsection of the occupancy chapters, related to protection from hazards, which leads the user to the mistaken belief that the terms *hazardous (contents) area* and *high hazard contents area* are synonymous. Building areas requiring protection by the [\\_\\_.3.2](#) subsection of an occupancy chapter are not necessarily high hazard areas. Often such areas are occupied by ordinary hazard materials in quantities exceeding those typically associated with the occupancy. For example, a storage room for office supplies in a business occupancy might be required to be protected as a hazardous area in accordance with [Section 8.7](#). Yet, the materials stored are the same ordinary hazard materials dispensed throughout the office area. See the differentiation made between hazardous areas and high hazard contents areas in [38.3.2.1](#) and [38.3.2.2](#) or [39.3.2.1](#) and [39.3.2.2](#). Each occupancy chapter's [\\_\\_.3.2](#) subsection is concerned with relative hazards — typically the presence of combustible materials in quantities exceeding those typical of the occupancy.

## 6.2.2 Classification of Hazard of Contents.

**6.2.2.1\* General.** The hazard of contents of any building or structure shall be classified as low, ordinary, or high in accordance with [6.2.2.2](#), [6.2.2.3](#), and [6.2.2.4](#).

**A.6.2.2.1** These classifications do not apply to the application of sprinkler protection classifications. See NFPA 13, *Standard for the Installation of Sprinkler Systems*. Depending on the use of the space, the area might require special hazard protection in accordance with [Section 8.7](#).

**6.2.2.2\* Low Hazard Contents.** Low hazard contents shall be classified as those of such low combustibility that no self-propagating fire therein can occur.

**A.6.2.2.2** [Chapter 42](#) recognizes storage of noncombustible materials as low hazard. In other occupancies, it is assumed that, even where the actual contents hazard is normally low, there is sufficient likelihood that some combustible materials or hazardous operations will be introduced in connection with building repair or maintenance, or some psychological factor might create conditions conducive to panic, so that the egress facilities cannot safely be reduced below those specified for ordinary hazard contents.

Very few occupancies qualify as having low hazard contents. When pressed for an example of low hazard contents, the cautious offer “pig iron ingots stored underwater.” A more realistic and useful example of low hazard contents might be metal parts stored in metal containers on metal — not wood — pallets supported by metal shelving. If the same metal parts stored in metal containers were placed on wood pallets, the pallets would be capable of sustaining a self-propagating fire, and the hazard of contents classification would be ordinary.

**6.2.2.3\* Ordinary Hazard Contents.** Ordinary hazard contents shall be classified as those that are likely to burn with moderate rapidity or to give off a considerable volume of smoke.

**A.6.2.2.3** Ordinary hazard classification represents the conditions found in most buildings and is the basis for the general requirements of this *Code*.

The fear of poisonous fumes or explosions is necessarily a relative matter to be determined on a judgment basis. All smoke contains some toxic fire gases but, under conditions of ordinary hazard, there should be no unduly dangerous exposure during the period necessary to escape from the fire area, assuming there are proper exits.

**6.2.2.4\* High Hazard Contents.** High hazard contents shall be classified as those that are likely to burn with extreme rapidity or from which explosions are likely. (*For means of egress requirements, see [Section 7.11](#).*)

**A.6.2.2.4** High hazard contents include occupancies where flammable liquids are handled or used or are stored under conditions involving possible release of flammable vapors; where grain dust, wood flour or plastic dust, aluminum or magnesium dust, or other explosive dusts are produced; where hazardous chemicals or explosives are manufactured, stored, or handled; where materials are processed or handled under conditions producing flammable flyings; and other situations of similar hazard.

[Chapters 40](#) and [42](#) include detailed provisions on high hazard contents.

Occupancies containing low hazard or high hazard contents are rare. In deciding which hazard classification applies, users need to ask the following questions:

1. Do the contents qualify for a low hazard classification?
2. Do the contents qualify for a high hazard classification?

If the answer to each of these questions is “no,” then the hazard of contents classification is ordinary.

Once an ordinary hazard contents classification is made, the application of *Code* requirements becomes simple, because the vast majority of the provisions are written to apply to ordinary hazard contents without mentioning ordinary hazard specifically. Generally, specialized requirements apply to high hazard contents, such as those specified in [Section 7.11](#), and to the few exceptions for which application is limited to low hazard contents, such as the unlimited travel distance permitted in low hazard storage occupancies by [Table 42.2.6](#).

# Means of Egress

The earliest editions of the *Life Safety Code* were titled *Building Exits Code*. The cover of the first edition is shown in [Exhibit 7.1](#). This title made it evident that one of the main themes addressed in the *Code* was that sufficient exits are needed to allow building occupants to leave a building safely during a fire or similar emergency.

The term *means of egress* is defined in [3.3.172](#) as “a continuous and unobstructed way of travel from any point in a building or structure to a public way consisting of three separate and distinct parts: (1) the exit access, (2) the exit, and (3) the exit discharge.” [Exhibit 7.2](#) illustrates the three-part means of egress. The interior carpeted corridor is the exit access, the door to the outside is the exit, and the outdoor walkway is the exit discharge. The concept of the three-part means of egress was made part of

the *Code* in 1956. Since that time, this concept has been well understood, and its philosophy has been implemented by code officials and building designers.

This chapter is segmented to describe the key elements that are typical of egress features.

Separation of the means of egress from other use areas is important to ensure a route of safe passage for the occupants. [Subsection 7.1.3](#) establishes a set of basic principles concerning the separation and segregation of exits to achieve this objective.

[Section 7.2](#) establishes criteria applicable to a variety of components that might constitute a part of the means of egress — from door assemblies and stairs (which are permitted by all occupancy chapters) to specialized components such as

**Exhibit 7.1**

First edition of the *Building Exits Code*.

**Exhibit 7.2**

The three-part means of egress — exit access, exit, and exit discharge. (Photo courtesy of Jake Pauls)

alternating tread devices (which are permitted by the occupancy chapters only within the constraints applied by this chapter, such as for the purposes of providing access to unoccupied roof spaces).

The method used to determine the number of occupants who can safely move through any of these individual components is addressed in [Section 7.3](#), which deals with the capacity of the means of egress. Part of this approach also involves establishing how many people can reasonably be expected to occupy a given area; [Section 7.3](#) also presents occupant load factors.

[Sections 7.4](#) through [7.7](#) relate to the number, arrangement, measurement, and discharge of the means of egress. These four sections not only address the proper number of exits and exit access points, they also control the distance to the exits and the placement of the exits with respect to one another.

The illumination of the means of egress, emergency lighting, and the marking of the means of egress with appropriate signage are related topics. The portions of this chapter that address these subjects were written in recognition of the fact that simply having enough exits that are properly arranged does not guarantee that the exits are readily apparent in a variety of circumstances. [Section 7.8](#) governs normal illumination for the means of egress, while emergency lighting provisions, which address the reillumination of means of egress routes upon loss of normal power, are covered in [Section 7.9](#). [Section 7.10](#) establishes the requirements for proper marking of the means of egress with various types of exit signs and directional exit signs.

[Sections 7.11](#) and [7.12](#) provide general rules for egress arrangement for high hazard areas and for mechanical equipment rooms.

[Section 7.13](#) addresses normally unoccupied building service equipment support areas (as found in attics, crawl spaces, chases, and interstitial areas where the space is vacant or intended exclusively for routing ductwork, cables, conduits, piping, and similar services and is rarely accessed). The provisions exempt such spaces from many of the egress provisions required of all other occupiable spaces in recognition of the fact that the lack of routine habitation in such spaces does not support the expense of providing traditional egress features. [Section 7.14](#) addresses elevators for occupant-controlled evacuation.

---

## 7.1 General

The purpose of [Chapter 7](#) is to establish minimum requirements for the means of egress for application to all occupancy classifications. In agreement with the [1.3.1](#) application statement, [Chapter 7](#) presents requirements that apply to both new construction and existing buildings (i.e., existing situations). Where the requirements of this chapter are unsuitable for a specific occupancy or impose an unreasonable burden on an existing facility, exemptions are provided as part of the text.

Sometimes the exemptions take the form of a concise statement that refers the user to the specific occupancy chapter. Only by consulting the complete text in the specific occupancy

chapter does the user learn the details of the exemption from the [Chapter 7](#) requirements. For example, where [7.2.1.5.1](#) requires that egress door assemblies remain unlocked, [7.2.1.5.4](#) cues the user to the fact that, for health care occupancies and detention and correctional occupancies, locked door assemblies are permitted under certain conditions. [Paragraph 7.2.1.5.4](#) uses the phrase “where otherwise provided in [Chapters 18](#) through [23](#)” to refer the user to chapters in which the details of the exemption’s conditions can be found. For example, [18.2.2.2.5.1](#) permits locked door assemblies in health care occupancies where the clinical needs of the patients require specialized security measures for their safety or where patients pose a security threat, with the provision that staff must be able to readily unlock the door assemblies at all times in accordance with the criteria of [18.2.2.2.6](#).

In addition to specifying means of egress features that are required to be provided in all occupancies, [Chapter 7](#) presents other features that, although not required, are permitted to be part of the means of egress if specified conditions are met. Recognizing that some provisions detailed in this chapter might not be suitable to a particular occupancy, the *Code* often introduces such features using the wording “where permitted in [Chapters 11](#) through [43](#).” For example, door assemblies in means of egress can be equipped with the access-controlled entrance and egress locking system addressed in [7.2.1.6.2](#) only where specifically permitted by an occupancy chapter. New business occupancies are permitted to use such a system via [38.2.2.2.6](#), which reads “access-controlled egress doors complying with [7.2.1.6.2](#) shall be permitted.” If an occupancy chapter is silent on the use of access-controlled egress door assemblies, such door assemblies are prohibited within the required means of egress serving that type of occupancy.

[Chapter 7](#) also presents features that are mandatory only when another part of the *Code* specifically requires the use of that component, system, or arrangement. Recognizing that some of the features detailed in this way in [Chapter 7](#) might not be necessary for a particular occupancy, the *Code* often introduces such features using the wording “where required in [Chapters 11](#) through [43](#).” For example, [Section 7.10](#) provides details for exit signs but does not require such signs. [Section 7.10](#) is written to include all the criteria necessary for providing exit signs if another part of the *Code* — typically an occupancy chapter — requires exit signs in accordance with [Section 7.10](#). New assembly occupancies require exit signs per [12.2.10.1](#), which reads “means of egress shall be provided with signs in accordance with [Section 7.10](#).”

Thus, some of the provisions of [Chapter 7](#) are absolute requirements that apply to all occupancies, unless specific exemptions are presented; some provisions are permitted to be used only if another part of the *Code* — typically an occupancy chapter — specifically includes language permitting such use; and some provisions apply only where another part of the *Code* — typically an occupancy chapter — specifically includes language requiring the use of that feature.

**7.1.1\* Application.** Means of egress for both new and existing buildings shall comply with this chapter. (See also 4.5.3.)

Means of egress are to comply with the requirements of this chapter and those detailed in Chapter 11, Chapters 12 through 42 for the appropriate occupancy, and Chapter 43. To avoid creating conflicting requirements, the occupancy chapters, Chapters 12 through 42, are permitted to establish provisions or requirements less stringent than those in Chapter 7 only if correlating language is added to the Chapter 7 requirement to which the exemption applies. However, if a provision of Chapters 11 through 43 is written to be more stringent than Chapter 7, it only needs to include the more strict requirement. In accordance with 4.4.2.3(1), where the specific requirements of Chapters 11 through 43 differ from the general requirements contained in Chapters 1 through 4 and Chapters 6 through 10, the more specific requirements of Chapters 11 through 43 govern. See also the commentary following 4.4.2.3.

**A.7.1.1** An installation of supplemental evacuation equipment is not recognized as a means of egress. Consequently, such equipment does not satisfy any requirement for minimum number of, capacity of, travel distance to, or remoteness of, means of egress.

Annex B, Supplemental Evacuation Equipment, is presented as a separate, adoptable annex of the Code. It is not part of Chapter 7, Means of Egress, because supplemental evacuation equipment, including platform rescue systems and controlled descent devices, is not credited with meeting any of the requirements for means of egress. Supplemental evacuation equipment is provided voluntarily to supplement the egress systems. Annex B helps to ensure that such equipment does not provide a false sense of security or interfere with the use of the required egress systems. See the commentary associated with Annex B.

## 7.1.2 Definitions.

**7.1.2.1 General.** For definitions see Chapter 3 Definitions.

**7.1.2.2 Special Definitions.** A list of special terms used in this chapter follows:

The occupants of a building must be protected from obstacles to safe egress. To achieve this goal, the protection of each component in the egress system is to be considered. Clear and concise definitions of the terms in 7.1.2.2 appear in Chapter 3. These definitions help explain the special features of each component. The term *means of egress* has been used for many years, but it was not until the late 1950s that its definition was expanded to comprise three separate and distinct parts: (1) the exit access, (2) the exit, and (3) the exit discharge. Prior to that, the term *exit* was used more often than the term *means of egress*, a fact evidenced by the Code's original title, *Building Exits Code*.

(1) **Accessible Area of Refuge.** See 3.3.22.1.

For an area of refuge to be considered an accessible area of refuge, it must be capable of being reached by a person in a wheelchair without traveling over stairs or other obstacles. ICC/ANSI

A117.1, *American National Standard for Accessible and Usable Buildings and Facilities*,<sup>1</sup> provides additional details on accessible routes. This edition of the *Life Safety Code* references the 2009 edition of ICC/ANSI A117.1. The 2009 edition, and its predecessor, the 2003 edition, are in harmony with the Americans with Disabilities Act Accessibility Guidelines for Buildings and Facilities (ADAAG),<sup>2</sup> which was revised to become ADA and ABA Accessibility Guidelines for Buildings and Facilities (ADA-ABA-AG).<sup>3</sup>

(2) **Accessible Means of Egress.** See 3.3.172.1.

A means of egress is considered an accessible means of egress if it meets one of the following criteria:

1. A wheelchair-bound person is able to travel unassisted through the exit access, exit, and exit discharge to a public way (i.e., ramp-type travel and not stair-type travel if elevation differences are involved).
2. A wheelchair-bound person is able to travel unassisted through that portion of the exit access necessary to reach an area of refuge.

The *area of refuge* specified in item 2 serves as a temporary haven from the effects of the fire. A person with severe mobility impairment must have the ability to travel from the area of refuge to the public way, although such travel might depend on the assistance of others. If elevation differences are involved, a special, protected elevator might be used, or the person might be carried on an extra-wide stair. See also 7.5.4.

(3) **Area of Refuge.** See 3.3.22.

The definition of *area of refuge* in 3.3.22 establishes the provisions that would create an area of refuge. Item (1) in 3.3.22 recognizes the combination of a sprinklered building and any story providing access to two accessible rooms or spaces separated from each other by smoke-resisting partitions. Some occupancy chapters exempt the occupancy from the criterion for the two accessible rooms or spaces separated from each other by smoke-resisting partitions. Those occupancy chapters recognize each story of a sprinklered building as being an area of refuge under the premise that it might be frightening to be left behind on such a floor without the ability to move to another room, but it is not dangerous, because the sprinkler system is designed to control the fire. See, for example, 28.2.2.12.2, 30.2.2.12.2, 36.2.2.12.2, and 38.2.2.12.2 for hotels and dormitories, apartment buildings, mercantile occupancies, and business occupancies, respectively.

(4) **Common Path of Travel.** See 3.3.47.

Common path of travel involves providing only one egress path for the initial portion of the exit access. The occupant does not have a choice of independent directions to travel. Common path of travel is addressed in 7.5.4.1.4 and the \_\_.2.5 subsection of the occupancy chapters. The occupancy chapter limitations on common path of travel are summarized in Table A.7.6.

(5) **Electroluminescent.** See 3.3.68.

(6) **Elevator Evacuation System.** See 3.3.69.

- (7) **Elevator Lobby.** See 3.3.70.
- (8) **Elevator Lobby Door.** See 3.3.62.1.

The terms *elevator evacuation system*, *elevator lobby*, and *elevator lobby door* are defined for purposes of applying 7.2.13. Although elevators are addressed in 7.2.13 as a component of a means of egress system, the restrictions imposed recognize the elevator only as a second means of egress from a tower with limited occupant load, without access by the general public, with sprinkler protection throughout the tower building, and with other detailed features. See also 11.3.2.2.2.

Section 7.14, Occupant Evacuation Elevators, appeared as Annex B in the 2009 edition of the *Code* and has been part of Chapter 7 since the 2012 edition. There is no assurance that elevators will remain in service for the time needed to evacuate the building, so such elevators are not credited with satisfying any means of egress requirements. Where elevators are used for occupant-controlled evacuation in accordance with the provisions of Section 7.14, the full complement of egress elements, routes, and systems must be provided as required by other provisions of Chapter 7 and the applicable occupancy chapter.

- (9) **Exit.** See 3.3.83.

The term *exit* is defined by 3.3.83 as that portion of a means of egress that is separated from other building spaces by enclosing it within construction, the fire resistance of which is specified by 7.1.3.2, with limited openings through the enclosing construction and protection of such openings. The exit might include door assemblies, stairs, ramps, smokeproof enclosures, exit passageways, and outside balconies. In each case, the exit components are required to conform to the *Code* specifications for fire protection, dimensions, and arrangement. In its simplest form, an exit is a doorway or a door opening directly to the exterior at grade. Such doorway or door opening provides the requisite protected way of travel to the exit discharge without the need for fire-rated, separating construction. An exit other than a door opening directly to the outside must provide a protected path of travel.

In the case of a stairway, the exit includes the door assembly into the stairway enclosure, the stair enclosure, the stairs and landings inside the enclosure, and the door assembly from the enclosure to the exterior or interior exit discharge.

The entrance to an exit enclosure is part of the exit and usually consists of a fire protection-rated door assembly that provides a protected entrance into a protected area. A fire door assembly, however, does not always signal an entrance to an exit. A door assembly or fire door assembly between a hotel room and a corridor or a fire door assembly across a corridor or lobby is part of exit access and not part of an exit, unless the corridor or lobby and all other openings into the corridor or lobby are separated and protected as required for an exit in accordance with 7.1.3.2, as might be accomplished using an exit passageway (see 7.2.6). Such protection is seldom provided for corridors, because, although it might be technically and monetarily

feasible at the time the exit passageway is constructed, it would be difficult to maintain over the life of the building, as penetrations for communications cabling and other rehabilitation projects diminish the protection features.

Various building features — where properly arranged, located, or constructed — might constitute an exit. Examples include an exterior exit door assembly, an exit passageway, a horizontal exit, an exit stair, or an exit ramp.

Several types of exits are shown in Exhibit 7.3 as light-blue shaded areas. On the second floor, exits include the following:

1. Two exit stairs enclosed by fire resistance-rated barriers, including a fire protection-rated, self-closing door assembly
2. Horizontal exit consisting of a fire resistance-rated barrier, including a pair of fire protection-rated, self-closing cross-corridor door assemblies that completely divide the floor into two fire compartments

On the first floor, exits include the following:

1. Two door assemblies from the corridor directly to the outside at grade level
2. Horizontal exit that is a vertical extension of, and, therefore, similar to, the horizontal exit located immediately above on the second floor
3. Exit passageway that connects one of the second-floor exit stair enclosures directly with the outside and is separated from the remainder of the first floor by fire resistance-rated barriers, including a fire protection-rated, self-closing door assembly from the room at the upper right corner

Note that the spiral stair connecting the first- and second-floor rooms at the upper right corner of the second floor in Exhibit 7.3 is not an exit. The spiral stair does not provide the separated and protected travel path required of an exit by 7.1.3.2.1. The spiral stair shown might have been installed in accordance with the convenience opening provisions of 8.6.9.1, with permission of the applicable occupancy chapter [e.g., see 38.3.1.1(1) for new business occupancies]. The spiral stair is a convenience opening that is prohibited by 8.6.9.1(6) from serving as a required means of egress.

For detailed requirements for a horizontal exit, see 7.2.4. For detailed requirements for an exit passageway, see 7.2.6.

- (10) **Exit Access.** See 3.3.84.

The exit access includes the rooms and building spaces people occupy and the door assemblies, aisles, corridors, unenclosed stairs, and unenclosed ramps that are traversed to reach an exit. Spaces constituting exit access are shown in Exhibit 7.4 as light-blue shaded areas. All spaces occupied and traversed in reaching an exit are considered the exit access portion of the means of egress. The shading shown in the exhibit indicates that exit access comprises more floor area than either of the other components of means of egress — the exit and exit discharge.

Exhibit 7.3

Various forms of exits.

Exhibit 7.4

Spaces constituting exit access.

The small closet in the room at the upper left corner of the first floor in [Exhibit 7.4](#) is judged to be not occupiable and, therefore, is not part of the exit access. Similarly, if an HVAC shaft were running up through the building, it too would be considered nonoccupiable and not part of the exit access.

Note that the two elevators are shaded so as to denote they are within the exit access. The elevators are not permitted to serve as components of the means of egress system (except for nonpublic towers in accordance with [7.2.13](#)). The building

occupants must be provided with egress components and paths independent of the elevators. Yet, the travel across the elevator floor to the corridor is exit access for the building occupants who find themselves on the elevator at the time the fire emergency is called to their attention.

The spiral stair connecting the first- and second-floor rooms at the upper right corner of the second floor in [Exhibit 7.4](#) is not an exit, as explained in the commentary associated with [7.1.2.2\(9\)](#), as it does not provide the separated and protected

travel path required of an exit by 7.1.3.2.1. The spiral stair shown might have been installed in accordance with the convenience opening provisions of 8.6.9.1, with permission of the applicable occupancy chapter [e.g., see 38.3.1.1(1) for new business occupancies]. The spiral stair is a convenience opening that is prohibited by 8.6.9.1(6) from serving as a required means of egress. Yet, travel on the spiral stair to reach an exit access path provided on the first floor or the second floor is exit access for the building occupants who find themselves on the spiral stair at the time the fire emergency is called to their attention.

(11) **Exit Discharge.** See 3.3.85.

Because some exits do not discharge directly into a public way, the exit discharge is defined as providing building occupants with a path of travel from the termination of an exit to a public way. This path of travel might be inside the building, as permitted by 7.7.2, or outside. Where an exit opens onto an alley, court, or yard, a safe path of travel is required to be provided to a public way or some equivalent safe area. This portion of the means of egress is the exit discharge. See also 7.7.1.

Forms of exit discharge are shown in Exhibit 7.5 as light-blue shaded areas. Because occupants leave the building at the first floor only, no exit discharge occurs on the second floor. The first-floor exit discharge includes the following:

1. Exterior space beginning at the corridor exit door assemblies in the exterior walls and continuing to the public way (street)
2. Exterior walkway along the side of the building beginning at the door assembly from the exit passageway and continuing to the public way
3. Interior path of travel from the second-floor exit stair discharging through a portion of the first-floor corridor

A portion of the first floor through which an occupant of the second floor needs to travel is considered exit discharge, because the occupant reaches a required exit on the second floor (i.e., the enclosed exit stair) and then is forced to leave that protected area after traveling through the stair enclosure door opening on the first floor. However, an occupant of the first floor who travels across the same space is considered to be within exit access and still en route to finding an exit, which occurs upon reaching the door opening to the outside. See also 7.7.2.

(12) **Externally Illuminated.** See 3.3.146.1.

(13) **Fire Exit Hardware.** See 3.3.135.1.

(14) **Horizontal Exit.** See 3.3.83.1.

A horizontal exit is a fire barrier with fire door assemblies that provides passage from one fire compartment of a building to another fire compartment in the same building or in an adjoining building on approximately the same level. Substantial fire separations are required, because the area to which egress is made serves as a temporary safe haven. The horizontal exit might be a combination of a 2-hour fire resistance-rated barrier separating a building into two areas with 1½-hour fire protection-rated door assemblies that allow travel from one side of the barrier to the other; or the horizontal exit might be a bridge or balcony that allows travel to an adjoining building. An example of a horizontal exit is depicted in Exhibit 7.3 by the barrier running across the center of the building, which provides a continuous separation from outside wall to opposite outside wall.

Horizontal exits are particularly useful in health care occupancies and in detention and correctional occupancies where they are important components of an effective defend-in-place

Spaces constituting exit discharge.

strategy. Horizontal exits make it possible to move nonambulatory patients horizontally to a temporary safe area rather than vertically down flights of stairs. They also provide added safety to residents of detention and correctional occupancies by allowing those residents to relocate within a building, rather than requiring that they rely on staff to unlock door assemblies to allow them to evacuate to the outside. For details on horizontal exits, see 7.2.4.

(15) **Internally Illuminated.** See 3.3.146.2.

(16) **Means of Egress.** See 3.3.172.

A means of egress, by definition, provides a path of egress travel to a public way. In effect, the *Code* emphasizes the need to move building occupants to a safe place. In means of egress arrangements for university campuses, military bases, resorts, and other large complexes, there are numerous areas a building occupant could reach before reaching a public way that afford the intended level of safety from a building fire. It is the *Code's* intent that occupants have the ability to move to a safe place from which they can continue to move away from the burning building as necessary. At that safe point, *Code* requirements cease to apply. This concept provides the basis for A.7.8.1.1, which is applicable to illumination of means of egress. This annex text states that the extent to which illumination needs to be provided outside the building — that is, within the exit discharge portion of the means of egress — should be to either a public way or a distance away from the building that is considered safe, whichever is closest to the building being evacuated.

From every location in a building, a means of egress or path of travel is required over which a person can move to gain access to the outside or to a place of safety. Any persons who gain entrance to a building usually have available to them that ingress route by which to egress. However, one important consideration makes egressing more than just reversing one's route of entry, especially if emergency conditions exist. This reverse route might consist of features that, although not obstacles upon entrance, prove to be such upon egress. For example, a door leaf hinged to swing in the direction of entry can become an obstacle when multiple occupants attempt to leave the building simultaneously in the opposite direction. The door leaf swings against the flow of traffic — a flow that, during emergency egress, is greatly increased, as compared with the leisurely flow of people entering a building. As another example, in assembly occupancies where turnstiles are used to meter ingress, reversing one's route often is not possible if additional openings independent of the turnstiles are not provided.

A basic principle of the *Code* requires that every component of a means of egress be operable by, and under the control of, the occupants attempting egress. Where the *Code* makes exemptions to this basic concept — for example, in health care occupancies where locked door assemblies are permitted if it is necessary for specialized protective measures or the clinical needs of the patients — it does so by substituting requirements adequate to achieve the same level of life safety as would

be provided if the means of egress system were fully under the control of the building occupants. For example, in the case of health care occupancy door assemblies that are locked for the clinical needs of the patients, staff is required to carry the keys needed to unlock those door assemblies at all times.

(17) **Panic Hardware.** See 3.3.135.2.

(18) **Photoluminescent.** See 3.3.209.

Photoluminescent materials have been used effectively as internally illuminated exit and directional exit signs in accordance with 7.10.7 and as floor proximity egress path marking in accordance with 7.10.1.7.

The provisions of 7.2.2.5.5 on exit stair path markings extend the use of photoluminescent materials as exit stair path markings. See 7.2.2.5.5.10. Exhibit 7.6 depicts the effectiveness of exit stair path marking via photoluminescent materials in a darkened exit stair enclosure.

**Exhibit 7.6**

*Photoluminescent exit stair path marking. (Photo courtesy of Jake Pauls)*

(19) **Ramp.** See 3.3.221.

Requirements for ramps used in a means of egress are found in 7.2.5.

(20) **Self-Luminous.** See 3.3.241.

See the commentary on photoluminescent materials that follows 7.1.2.2(18). Photoluminescent materials are a form of self-luminous materials.

(21) **Severe Mobility Impairment.** See 3.3.246.

See also 7.5.4.1, which requires new areas accessible to persons with severe mobility impairment to be provided with accessible means of egress. See the commentary that follows 7.1.2.2(1).

(22) **Smokeproof Enclosure.** See 3.3.257.

### 7.1.3 Separation of Means of Egress. See also Section 8.2.

**7.1.3.1 Exit Access Corridors.** Corridors used as exit access and serving an area having an occupant load exceeding 30 shall be separated from other parts of the building by walls having not less than a 1-hour fire resistance rating in accordance with Section 8.3, unless otherwise permitted by one of the following:

- (1) This requirement shall not apply to existing buildings, provided that the occupancy classification does not change.
- (2) This requirement shall not apply where otherwise provided in Chapters 11 through 43.

Paragraph 7.1.3.1 requires protection via fire-rated corridor walls of exit access corridors serving more than 30 occupants. Note that the requirement for the corridor walls to be fire resistance rated, which is not a requirement for the floor/ceiling or roof/ceiling assemblies forming the top and bottom of the corridor compartment, provides separation only between the corridor and other spaces on the same floor. To provide the 1-hour separation between the corridor and the remainder of the floor, as required by 7.1.3.1, the fire barriers forming the corridor walls must extend above any ceiling membranes so as to be sealed tightly against the floor or roof above.

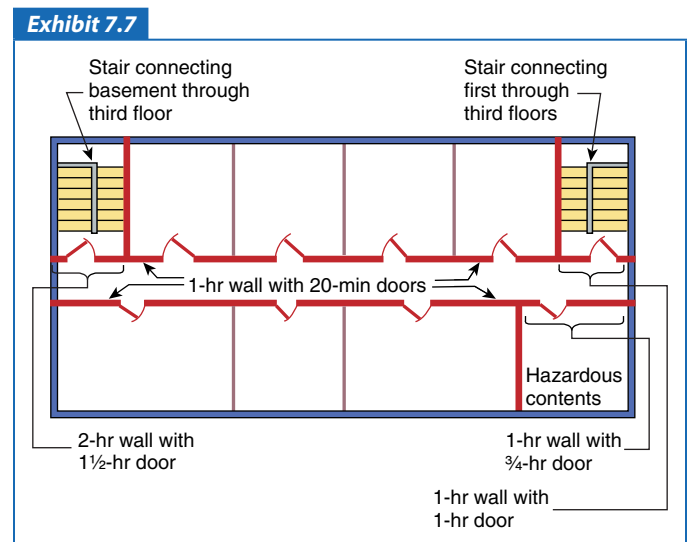

To learn if any separation between the corridor and spaces on floors above or below is required, one has to rely on, for example, the provisions of 8.6.1(1) to ensure that the floor is constructed as a smoke barrier — or the provisions of subsection \_\_.1.6 of an occupancy chapter that require fire resistance-rated floor construction.

Paragraph 7.1.3.1(1) exempts existing corridors, provided that the occupancy classification does not change. Therefore, if the occupancy classification of an existing building does change, the 1-hour corridor wall requirement applies, unless the specific occupancy involved has different requirements. Most of the occupancy chapters establish new exit access corridor wall requirements that supersede the requirements of 7.1.3.1. Also, some of the occupancy chapters establish corridor wall requirements for existing buildings. Such provisions usually appear in subsection \_\_.3.6. For example, 14.3.6 addresses special requirements for corridor walls in new educational occupancies, and 15.3.6 addresses special requirements for corridor walls in existing educational occupancies. If no special requirements appear in an occupancy chapter, the provisions of 7.1.3.1 prevail.

Paragraph 7.1.3.1 does not require corridors; however, it does require that, where corridors do exist and where they serve an area having an occupant load of more than 30 persons, they must be separated from other (i.e., noncorridor) spaces on that floor by corridor walls. Section 8.3 regulates the construction of the fire barrier forming the corridor walls and the opening protection. Wall segments that serve both as a corridor wall and as part of an exit enclosure must meet the more stringent provisions required for the enclosure of exits. Similarly, wall segments that serve both as a corridor wall and enclosure protection of

hazardous contents areas must meet the more stringent of the applicable provisions. In some cases, the provisions for corridor walls and those for hazardous area protection require a minimum 1-hour fire resistance rating. Yet, the minimum required fire protection rating of door assemblies in such walls might vary, with a minimum 45-minute rating required for the hazardous area protection and only a 20-minute rating for the corridor wall. Determining which set of requirements is more stringent involves comparing all related requirements, not only the fire resistance rating of the wall.

Exhibit 7.7 is an example of the protection of exit access corridors required by 7.1.3.1. Note the difference in the required protection for the corridor wall segments serving also as enclosure protection from the hazardous contents area (see Section 8.7) and as part of the enclosure of an exit (see 7.1.3.2).

Protection of exit access corridors.

### 7.1.3.2 Exits.

**7.1.3.2.1** Where this Code requires an exit to be separated from other parts of the building, the separating construction shall meet the requirements of Section 8.2 and the following:

- (1)\* The separation shall have a minimum 1-hour fire resistance rating where the exit connects three or fewer stories.

**A.7.1.3.2.1(1)** In existing buildings, existing walls in good repair and consisting of lath and plaster, gypsum wallboard, or masonry units can usually provide satisfactory protection for the purposes of this requirement where a 1-hour fire resistance rating is required. Further evaluation might be needed where a 2-hour fire resistance rating is required. Additional guidelines can be found in Annex O of NFPA 914, *Code for Fire Protection of Historic Structures*, and in the *SFPE Handbook of Fire Protection Engineering*.

- (2) The separation specified in 7.1.3.2.1(1), other than an existing separation, shall be supported by construction having not less than a 1-hour fire resistance rating.
- (3)\* The separation shall have a minimum 2-hour fire resistance rating where the exit connects four or more stories, unless one of the following conditions exists:
  - (a) In existing non-high-rise buildings, existing exit stair enclosures shall have a minimum 1-hour fire resistance rating.
  - (b) In existing buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7, existing exit stair enclosures shall have a minimum 1-hour fire resistance rating.
  - (c) The minimum 1-hour enclosures in accordance with 28.2.2.1.2, 29.2.2.1.2, 30.2.2.1.2, and 31.2.2.1.2 shall be permitted as an alternative to the requirement of 7.1.3.2.1(3).

**A.7.1.3.2.1(3)** In existing buildings, existing walls in good repair and consisting of lath and plaster, gypsum wallboard, or masonry units can usually provide satisfactory protection for the purposes of this requirement where a 1-hour fire resistance rating is required. Further evaluation might be needed where a 2-hour fire resistance rating is required. Additional guidelines can be found in Annex O of NFPA 914, *Code for Fire Protection of Historic Structures*, and in the *SFPE Handbook of Fire Protection Engineering*.

- (4) Reserved.
- (5) The minimum 2-hour fire resistance-rated separation required by 7.1.3.2.1(3) shall be constructed of an assembly of noncombustible or limited-combustible materials and shall be supported by construction having a minimum 2-hour fire resistance rating, unless otherwise permitted by 7.1.3.2.1(7).
- (6)\* Structural elements, or portions thereof, that support exit components and either penetrate into a fire resistance-rated assembly or are installed within a fire resistance-rated wall assembly shall be protected, as a minimum, to the fire resistance rating required by 7.1.3.2.1(1) or (3).

**A.7.1.3.2.1(6)** It is not the intent to require the structural elements supporting outside stairs, or structural elements that penetrate within exterior walls or any other wall not required to have a fire resistance rating, to be protected by fire resistance-rated construction.

- (7) In Type III, Type IV, and Type V construction, as defined in NFPA 220, *Standard on Types of Building Construction* (see 8.2.1.2), fire retardant-treated wood enclosed in noncombustible or limited-combustible materials shall be permitted.
- (8) Openings in the separation shall be protected by fire door assemblies equipped with door closers complying with 7.2.1.8.

- (9)\* Openings in exit enclosures shall be limited to door assemblies from normally occupied spaces and corridors and door assemblies for egress from the enclosure, unless one of the following conditions exists:
  - (a) Vestibules that separate normally unoccupied spaces from an exit enclosure shall be permitted, provided the vestibule is separated from adjacent spaces by corridor walls and related opening protectives as required for the occupancy involved but not less than a smoke partition in accordance with Section 8.4.
  - (b) In buildings of Type I or Type II construction, as defined in NFPA 220, *Standard on Types of Building Construction*, (see 8.2.1.2) fire protection-rated door assemblies to normally unoccupied building service equipment support areas as addressed in Section 7.13 shall be permitted, provided the space is separated from the exit enclosure by fire barriers as required by 7.1.3.2.1(3).
  - (c) Openings in exit passageways in mall buildings as provided in Chapters 36 and 37 shall be permitted.
  - (d) In buildings of Type I or Type II construction, as defined in NFPA 220, *Standard on Types of Building Construction*, (see 8.2.1.2) existing fire protection-rated door assemblies to interstitial spaces shall be permitted, provided that such spaces meet all of the following criteria:
    - i. The space is used solely for distribution of pipes, ducts, and conduits.
    - ii. The space contains no storage.
    - iii. The space is separated from the exit enclosure in accordance with Section 8.3.
  - (e) Existing openings to mechanical equipment spaces protected by approved existing fire protection-rated door assemblies shall be permitted, provided that the following criteria are met:
    - i. The space is used solely for non-fuel-fired mechanical equipment.
    - ii. The space contains no storage of combustible materials.
    - iii. The building is protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7.

**A.7.1.3.2.1(9)** Means of egress from the level of exit discharge is permitted to pass through an exit stair enclosure or exit passageway serving other floors. Doors for convenience purposes and unrelated to egress also are permitted to provide access to and from exit stair enclosures and exit passageways, provided that such doors are from corridors or normally occupied spaces. It is also the intent of this provision to prohibit exit enclosure windows, other than approved vision panels in doors, that are not mounted in an exterior wall.

- (10) Penetrations into, and openings through, an exit enclosure assembly shall be limited to the following:
- Door assemblies permitted by 7.1.3.2.1(9)
  - \* Electrical conduit serving the exit enclosure
  - Required exit door openings
  - Ductwork and equipment necessary for independent stair pressurization
  - Water or steam piping necessary for the heating or cooling of the exit enclosure
  - Sprinkler piping
  - Standpipes
  - Existing penetrations protected in accordance with 8.3.5
  - Penetrations for fire alarm circuits, where the circuits are installed in metal conduit and the penetrations are protected in accordance with 8.3.5

**A.7.1.3.2.1(10)(b)** Penetrations for electrical wiring are permitted where the wiring serves equipment permitted by the authority having jurisdiction to be located within the exit enclosure, such as security systems, public address systems, and fire department emergency communications devices.

- Penetrations or communicating openings shall be prohibited between adjacent exit enclosures.
- Membrane penetrations shall be permitted on the exit access side of the exit enclosure and shall be protected in accordance with 8.3.5.6.

Exits must provide protection from fire originating inside or outside the exit. Protection from fire originating within the enclosure is accomplished by prohibiting use of the enclosure for any purpose that could possibly interfere with the exit functioning as a protected path of travel (see 7.1.3.2.3) and by limiting the combustibility of interior wall, ceiling, and floor finish materials within exit enclosures (see 7.1.4). Details on interior wall, ceiling, and floor finish are contained in Section 10.2 and subsection 10.2.3 of Chapters 12 through 42.

Protection from fire originating outside the exit enclosure is accomplished by providing separating construction having the required specified degree of fire resistance and by careful control of openings into the exit enclosure itself. The only openings permitted in the fire barriers between the exit and the building spaces are those for entering the exit from any normally occupied space or corridor and those for leaving the exit to reach the exit discharge. In other words, only openings provided for an occupant to enter and leave the exit enclosure are permitted.

Exhibit 7.8 depicts an egress arrangement on the ground floor of a building where occupants of that floor can enter the two exit stair enclosures, although such door assemblies are not required, because the door assemblies at the end of the corridor that discharge directly outside provide the required means of egress for the ground floor occupants. Earlier editions of the Code limited door assemblies into exit stair enclosures to those necessary for access to the enclosure. Some authorities having

Exhibit 7.8

Convenience door assemblies permitted from ground floor into exit enclosure.

jurisdiction (AHJs) interpreted that limitation as prohibiting the convenience door assembly from the ground floor to the exit stair enclosure. The Code was revised to delete the concept of necessity for openings and states that openings in exit enclosures are limited to door assemblies from normally occupied spaces and corridors and door assemblies for egress from the enclosure. Thus, the arrangement depicted in Exhibit 7.8, with the convenience door assemblies into the stair enclosures on the ground floor, is permitted.

The required degree of fire resistance-rated separation for the exit enclosure depends on the number of stories or floor levels the exit connects, not the height of the building. It is possible to have stairs in a high-rise building connecting only three or fewer stories. In such a case, the enclosing construction is not required to be more than 1-hour fire resistance rated. See Exhibit 7.9. Where connecting four stories or more, exit stairs must be separated from other spaces within the building by 2-hour fire resistance-rated

Exhibit 7.9

Required separating construction for exit stairs.

noncombustible, limited-combustible, or fire-retardant-treated wood construction. Where connecting three or fewer stories, the separation is permitted to be reduced to a minimum 1-hour rating. Via 7.1.3.2.1(3)(a) and 7.1.3.2.1(3)(b), existing exit stair enclosures in existing non-high-rise buildings or in existing sprinklered buildings — regardless of height — are permitted a 1-hour fire resistance rating. As indicated by 7.1.3.2.1(3)(c), some occupancy chapters reduce the 2-hour fire resistance-rated construction requirement to 1 hour — even for new construction — if the building is protected throughout by an approved, supervised automatic sprinkler system. An example can be found in 28.2.2.1.2, applicable to new hotels.

The door assemblies in walls of exit enclosures are to be 1-hour fire protection-rated door assemblies where used in 1-hour fire resistance-rated enclosures, and 1½-hour fire protection-rated door assemblies where used in 2-hour fire resistance-rated enclosures. See Table 8.3.4.2. Paragraph 8.3.4.3 modifies the provisions of Table 8.3.4.2 by permitting existing ¾-hour fire protection-rated door assemblies to continue in use in lieu of the minimum 1-hour fire protection rating required by the table.

If a pair of fire door leaves opening in the same direction without a center mullion post between the door leaf panels is to be used in an opening in an exit enclosure, it would be prudent to choose a pair of door leaves listed for use without an overlapping astragal plate. Pairs of door leaves with an astragal must be arranged to close in a particular sequence to ensure full closure. A coordinator is required to accomplish the sequential closing, and the record of coordinators functioning properly is poor. However, a pair of door leaves without an astragal could allow the passage of considerable smoke through any gap between the meeting edges of the leaves and into the exit; therefore, the use of pairs of fire door leaves opening in the same direction into an exit enclosure, without a center mullion post, should be discouraged.

The provision of 7.1.3.2.1(2) applies a requirement to 1-hour fire resistance-rated exit enclosure barriers similar to that applied to 2-hour barriers by 7.1.3.2.1(5) relative to providing a fire rating for the supporting construction. The provisions of 7.1.3.2.1(5) and (7) work together to limit the combustibility of the minimum 2-hour fire resistance-rated separating construction required by 7.1.3.2.1(3). Additionally, such 2-hour separating construction must be supported by construction having a minimum 2-hour fire resistance rating. The effect of this requirement is that, in a building with floor/ceiling assemblies of less than a 2-hour fire resistance rating, the exit stair enclosure fire barrier walls are not permitted to be supported by the building floors. Rather, the exit stair enclosure needs to be a self-supporting shaft system.

The provision of 7.1.3.2.1(6) supplements the requirement of 7.1.3.2.1(5) to help ensure that structural elements that support exit stair components are protected to the same level as required for the exit enclosure. The provision helps to prevent the early failure of exit enclosures and related egress elements.

For example, a hanger rod supporting a stair landing must not be installed within a wall cavity, as the cavity and outer wall membrane do not provide the required minimum fire resistance rating that the entire wall assembly provides (i.e., the fire resistance rating achieved by the combination of the outer wall membrane, cavity, and inner wall membrane). The text of A.7.1.3.2.1(6) clarifies that outside walls that are not required to be fire rated to complete the separation of the exit stair from the remainder of the floor are permitted to be penetrated by structural elements, such as the stair landing hanger rod referenced earlier in this paragraph.

In accordance with 7.1.3.2.1(9), the only openings permitted in the exit enclosure are for door assemblies providing access into the enclosure from normally occupied spaces and corridors and for door assemblies providing egress from the enclosure into the exit discharge. These door assemblies are required to be self-closing fire door assemblies as described in 7.2.1.8. No opening through the exit enclosure walls — including a door opening — is permitted from storage rooms, closets, boiler rooms, equipment spaces, utility rooms, electrical vaults, or similar spaces that are not normally occupied. Access panels to access building spaces cannot be installed in the walls or ceilings of exit enclosures, regardless of whether the access panels have a fire resistance rating.

The provision of 7.1.3.2.1(9)(a) is new to the 2015 edition of the Code. It recognizes the often practiced, but heretofore non-compliant, arrangement whereby a vestibule is created to prevent a normally unoccupied space from opening directly onto an exit enclosure. Exhibit 7.10 depicts a fuel-fired mechanical equipment room that is to be considered as a normally unoccupied space. The vestibule and associated door that opens directly into the room comply with the corridor wall and door provisions of the applicable occupancy chapter. Where an occupancy chapter requires no corridor separation, as is the case with existing

*Vestibule separating exit enclosure from normally unoccupied space.*

business occupancies per 39.3.6, the vestibule barriers must be smoke partitions. The corridor is permitted to open directly onto the stair per 7.1.3.2(9). Similarly, normally occupied spaces are permitted to open directly onto the exit enclosure.

The provision of 7.1.3.2.1(9)(b) is new to the 2015 edition of the Code. It treats a normally unoccupied building service equipment support area (see Section 7.13) as a normally occupied space, but it requires that the separation between such space and the exit enclosure be based on the provisions applicable to an exit enclosure that connects four or more stories. In other words, a minimum 2-hour fire resistance-rated separation is required unless one of the exemptions to 7.1.3.2(3) is met, in which case a minimum 1-hour fire resistance-rated separation is required.

Paragraph 7.1.3.2.1(9)(c) permits openings from normally unoccupied spaces within the exit enclosures created by exit passageways in mall buildings, as detailed in Chapters 36 and 37. By consulting the provisions of 36.4.4.6.2 and 37.4.4.6.2, one finds that rooms housing building service equipment, service elevators, and janitor closets — spaces not normally occupied — are permitted to open directly onto mall building exit passageways. For an explanation of this deviation from the requirement of 7.1.3.2.1(9), see the commentary following 36.4.4 and 37.4.4.

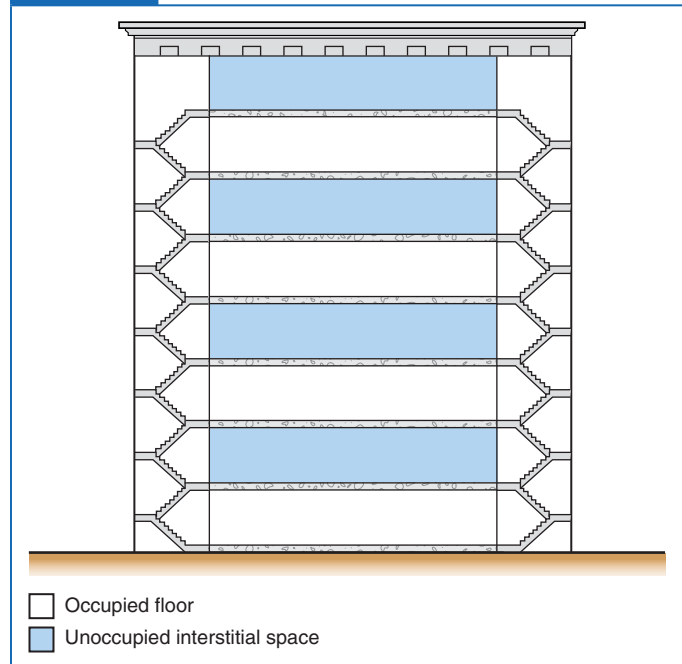

Paragraph 7.1.3.2.1(9)(d) recognizes that, in some existing buildings, it is safe to permit unoccupied rooms to open directly onto an exit stair enclosure. For example, in some existing hospitals, it is common to have interstitial spaces above the ceiling of each floor for purposes of running pipes, ducts, and conduits. The interstitial spaces appear much like separate floors. For example, in an elevation view of a four-story hospital, it would appear that there are eight stories. Patients would occupy every other floor, and the alternating “floors” created by the interstitial spaces would house the service pipes, ducts, and conduits. This arrangement is depicted in Exhibit 7.11. Access to the patient floors and to the interstitial space “floors” would be by means of fire protection-rated door assemblies from the stair enclosure. See 7.1.3.2.1(9)(b) for the other criteria necessary to permit the existing situation to be continued in use.

Exit enclosure penetrations generally are prohibited for new construction. Penetrations for ductwork for pressurization of smokeproof enclosures might be permitted (see 7.2.3), but penetration by other ductwork is prohibited. Penetrations are permitted by 7.1.3.2.1(10) for the following:

1. Water and steam piping necessary for the heating and cooling of the exit enclosure
2. Electrical conduit serving the exit enclosure
3. Fire alarm system circuit wiring installed in metallic conduit and serving the building
4. Standpipe and sprinkler piping serving the building

The technical committee carefully compiled the list of penetrations permitted by 7.1.3.2.1(10) to be a complete list rather than a partial list of examples. Given that fire alarm system circuit wiring installed in metallic conduit is permitted, some designers

Exhibit 7.11

Unoccupied interstitial spaces with openings to exit stair enclosure.

and contractors have attempted to justify placing control panels within the exit enclosure. It was not the committee's intent to permit fire alarm system controls and associated components, other than circuit wiring in metallic conduit, to be installed within the exit enclosure.

Exhibit 7.12 shows fire protection and alarm system features installed within an exit enclosure. The equipment is connected to equipment outside the enclosure via penetrations of the enclosing fire barriers. Some of the penetrations are specifically permitted by 7.1.3.2.1(10) and others might fall into the category of existing penetrations protected in accordance with 8.3.5 as permitted by 7.1.3.2.1(10)(h). Other items, such as the fire alarm system cabinets, should not be within the exit enclosure.

Openings to the exterior of the building are not regulated, provided that there is no potential fire exposure from an adjacent source. Such openings need not be protected with fire protection-rated assemblies, because they are not separating the exit from other parts of the building. However, where the exterior wall of the exit stair enclosure is not fire resistance rated, such stair is subject to the provisions of 7.2.2.5.2. See Figure A.7.2.2.5.2(c) for an example of the fire-rated separating construction needed for an exterior wall segment adjacent to, and exposing, the nonrated exterior wall of an exit stair enclosure at an angle of less than 180 degrees.

The provision of 7.1.3.2.1(12) recognizes that the purpose of 7.1.3.2.1 is to limit through-penetrations into an exit enclosure but not to prohibit membrane penetrations on the outside of the exit enclosure. This provision allows for membrane penetrations, such as those for the installation of fire alarm system

Exhibit 7.12

Fire protection and alarm equipment within, and penetrating the barrier walls of, an exit enclosure. (Photo courtesy of Jake Pauls)

manual fire alarm boxes next to the door, into the stair enclosure. In prior editions, such membrane penetrations on the outside of the exit enclosure were not addressed, as they were not specifically permitted by 7.1.3.2.1(10).

**7.1.3.2.2** An exit enclosure shall provide a continuous protected path of travel to an exit discharge.

**Paragraph 7.1.3.2.2** emphasizes that exit enclosures, and the protection they afford the occupants, must be continuous. It is a fundamental premise that, once an occupant has been provided the level of protection afforded by an exit, that level of protection must be maintained to the exit discharge.

**Paragraph 7.1.3.2.2** prohibits an exit stair or exit ramp arrangement that requires a person to leave the exit enclosure, become exposed to conditions on a floor, and then re-enter the exit enclosure to continue moving to the exit discharge. **Exhibit 7.13** shows an unacceptable arrangement. The discontinuity of leaving the stair enclosure, and then re-entering the stair enclosure to continue moving to the level of exit discharge, creates too great a potential for exposing occupants to danger and blocking their egress route.

**7.1.3.2.3\*** An exit enclosure shall not be used for any purpose that has the potential to interfere with its use as an exit and, if so designated, as an area of refuge. (See also 7.2.2.5.3.)

**A.7.1.3.2.3** This provision prohibits the use of exit enclosures for storage or for installation of equipment not necessary for

Exhibit 7.13

Unacceptable arrangement for enclosing a stair serving as a required exit.

safety. Occupancy is prohibited other than for egress, refuge, and access. The intent is that the exit enclosure essentially be “sterile” with respect to fire safety hazards.

**Paragraph 7.1.3.2.3** prohibits the use of an exit enclosure for any purpose that could potentially interfere with its use as an exit or as an area of refuge. For example, use of an enclosed exit stair to house vending machines, copying machines, or storage, or to run electrical distribution wires and cables to areas of the building, is prohibited. Standpipes and emergency lighting that are part of the life safety features are permitted only if their arrangement does not interfere with the passage of people. This limitation covers more than mechanical obstruction of the egress path; it includes any use that could interfere with the use of the exit. See also 7.1.10.1 and 7.2.2.5.3.

**Exhibit 7.14** shows rolled carpet on a stair landing within an exit enclosure. The presence of the carpeting violates the requirement of 7.1.3.2.3 in two ways:

1. The carpet encroaches on the required egress width.
2. If the combustible carpet were to burn, the resultant heat and smoke would prevent the exit enclosure from serving its intended use.

Exhibit 7.14

Rolled carpet stored in an exit enclosure. (Photo courtesy of Jake Pauls)

The prohibitions of 7.1.3.2.3 also apply to exit passageways, because they also are exit enclosures.

#### 7.1.4 Interior Finish in Exit Enclosures.

**7.1.4.1\* Interior Wall and Ceiling Finish in Exit Enclosures.** Interior wall and ceiling finish shall be in accordance with Section 10.2. In exit enclosures, interior wall and ceiling finish materials complying with Section 10.2 shall be Class A or Class B.

**A.7.1.4.1** See Chapters 12 through 42 for further limitations on interior wall and ceiling finish.

**7.1.4.2\* Interior Floor Finish in Exit Enclosures.** New interior floor finish in exit enclosures, including stair treads and risers, shall be not less than Class II in accordance with Section 10.2.

**A.7.1.4.2** See Chapters 12 through 42 for further limitations on interior floor finish.

Paragraph 7.1.4.1 regulates interior wall and ceiling finish within exit enclosures, such as enclosed exit stairs. The intent is to minimize the possibility of fire spreading into and within the exit enclosure. Except as modified by occupancy Chapters 12 through 42, the interior wall and ceiling finish in exit enclosures is required to be either Class A or Class B, as detailed in Section 10.2. Per the provisions of 10.2.8.1, Class C interior wall and ceiling finish would be permitted within an exit enclosure if automatic sprinklers protected the enclosure and adjacent areas of the building.

As explained in the commentary following 4.4.2.3, the occupancy chapters can modify the requirements of Chapters 1 through 4 and Chapters 6 through 10. In some cases, the modification results in a more stringent requirement. In others, the result is a relaxation of a base chapter requirement. Interior finish is addressed in detail in Section 10.2, with specific limitations in subsection \_\_.3.3 of the occupancy chapters. For example, for new interior wall and ceiling finish materials in health care occupancies, the requirements of 18.3.3 result in more stringent criteria for wall and ceiling finish within exit enclosures than are required by 7.1.4. Where new interior wall finish is installed in a nonsprinklered health care occupancy, the requirement is for Class A — not Class B — materials. If the enclosure and adjacent smoke compartments of the building are sprinklered, the requirement is for Class B — not Class C — materials. In this case, the occupancy chapter, considering the needs of its typical occupant group (i.e., persons incapable of self-preservation for whom a defend-in-place strategy is employed), tailors its provisions to help achieve the intended minimum level of life safety.

#### 7.1.5\* Headroom.

**A.7.1.5** For the purpose of this requirement, projections include devices such as lighting equipment, emergency signaling equipment, environmental controls and equipment, security devices, signs, and decorations that are typically limited in area.

**7.1.5.1** Means of egress shall be designed and maintained to provide headroom in accordance with other sections of this Code, and such headroom shall be not less than 7 ft 6 in. (2285 mm), with projections from the ceiling not less than 6 ft 8 in. (2030 mm) with a tolerance of  $-3/4$  in. (-19 mm), above the finished floor, unless otherwise specified by any of the following:

- (1) In existing buildings, the ceiling height shall be not less than 7 ft (2135 mm) from the floor, with projections from the ceiling not less than 6 ft 8 in. (2030 mm) nominal above the floor.
- (2) Headroom in industrial equipment access areas as provided in 40.2.5.3 shall be permitted.

**7.1.5.2** The minimum ceiling height shall be maintained for not less than two-thirds of the ceiling area of any room or space, provided that the ceiling height of the remaining ceiling area is not less than 6 ft 8 in. (2030 mm).

**7.1.5.3** Headroom on stairs shall be not less than 6 ft 8 in. (2030 mm) and shall be measured vertically above a plane parallel to, and tangent with, the most forward projection of the stair tread.

The minimum 7 ft 6 in. (2285 mm) ceiling height and the minimum 6 ft 8 in. (2030 mm) clearance below any projections descending from the minimum ceiling height is expressed with a tolerance of  $-3/4$  in. (-19 mm) rather than as an absolute minimum height. Thus, it is the intent of 7.1.5.1 to recognize the clearance provided in passing through the door frame opening associated with a standard 6 ft 8 in. (2030 mm) door leaf where the door stop built into the door frame at the top of the door opening encroaches on the height of the opening. Paragraph 7.1.5.3 and the dimensional criteria of 7.2.2.2.1 also permit the 6 ft 8 in. (2030 mm) minimum headroom height on stairways. Paragraph 7.1.5.3 explains how to measure the headroom on stairs. Headroom measurement is illustrated in Exhibit 7.15. The dimension 6 ft 8 in. (2030 mm) is permitted for projections descending from the ceiling and for stairs.

Earlier editions of the Code left unanswered the question of how many 6 ft 8 in. (2030 mm) projections are too many, so as to leave too little area with at least 7 ft 6 in. (2285 mm) of headroom

Headroom measurement.

height. Since the 2000 edition, 7.1.5.2 has required the 7 ft 6 in. (2285 mm) minimum headroom to be maintained for at least two-thirds of the ceiling area of any room or space.

For industrial occupancies, 40.2.5.3 extends the use of the minimum 6 ft 8 in. (2030 mm) headroom allowance to industrial equipment access walkways, platforms, ramps, and stairs that serve as a component of the means of egress for not more than 20 people.

## 7.1.6 Walking Surfaces in the Means of Egress.

### 7.1.6.1 General.

7.1.6.1.1 Walking surfaces in the means of egress shall comply with 7.1.6.2 through 7.1.6.4.

7.1.6.1.2 Approved existing walking surfaces shall be permitted.

7.1.6.2 **Changes in Elevation.** Abrupt changes in elevation of walking surfaces shall not exceed ¼ in. (6.3 mm). Changes in elevation exceeding ¼ in. (6.3 mm), but not exceeding ½ in. (13 mm), shall be beveled with a slope of 1 in 2. Changes in elevation exceeding ½ in. (13 mm) shall be considered a change in level and shall be subject to the requirements of 7.1.7.

### 7.1.6.3 Level.

7.1.6.3.1 Walking surfaces shall comply with all of the following:

- (1) Walking surfaces shall be nominally level.
- (2) The slope of a walking surface in the direction of travel shall not exceed 1 in 20, unless the ramp requirements of 7.2.5 are met.
- (3) The slope perpendicular to the direction of travel shall not exceed 1 in 48.

7.1.6.3.2 Vehicle ramps in parking structures, as permitted in 42.8.2.2.6, and not on an accessible means of egress or other accessible element shall be exempt from the provisions of 7.1.6.3.1.

7.1.6.4\* **Slip Resistance.** Walking surfaces in the means of egress shall be slip resistant under foreseeable conditions.

A.7.1.6.4 The foreseeable slip conditions are those that are likely to be present at the location of the walking surface during the use of the building or area. Examples of foreseeable conditions include a swimming pool deck and exterior means of egress, generally, that are likely to be wet.

Regarding the slip resistance of treads, it should be recognized that, when walking up or down stairs, a person's foot exerts a smaller horizontal force against treads than is exerted when walking on level floors. Therefore, materials used for floors that are acceptable as slip resistant (as described by ASTM F 1637, *Standard Practice for Safe Walking Surfaces*) provide adequate slip resistance where used for stair treads. Such slip resistance includes the important leading edges of treads, the part of the

tread that the foot first contacts during descent, which is the most critical direction of travel. If stair treads are wet, there is an increased danger of slipping, just as there is an increased danger of slipping on wet floors of similar materials. A small wash or drainage slope on exterior stair treads is, therefore, recommended to shed water. (See *Templer, J. A., The Staircase: Studies of Hazards, Falls, and Safer Design*, Cambridge, MA: MIT Press, 1992.)

The vast majority of a building occupant's egress travel time is spent on walking surfaces, rather than passing through door assemblies or traversing other egress components detailed in Section 7.2. Yet, editions of the Code prior to 2000 remained silent on the needed characteristics of walking surfaces.

The current provisions applicable to walking surfaces are minimal. They address elevation changes that might cause tripping hazards, maximum slope, and slip resistance that relates to safe use.

Small changes in elevation are often not perceptible to the person using the walking surface. Exhibit 7.16 simulates the walking surface user's foot contacting the lip where the walking surface elevation varies. Exhibit 7.17 simulates the walking surface user misstepping and beginning to fall.

By addressing, for example, slip resistance in the generalized paragraph applicable to walking surfaces (see 7.1.6.4), it is no longer necessary to repeat similar provisions for the applicable components of means of egress, such as ramps, stair treads, and landing surfaces. It is expected that the provisions of 7.1.6 will be further expanded, such as by codifying measurable slip-resistance criteria, for future editions of the Code. The technology has not yet evolved to the degree needed to achieve technical committee consensus on which provisions need to be mandated and which equipment is to be used to take measurements for judging compliance with the criteria mandated. In Exhibit 7.18 a tribometer, although not required by this Code, is used to evaluate slip resistance.

## 7.1.7 Changes in Level in Means of Egress.

7.1.7.1 Changes in level in means of egress shall be achieved by an approved means of egress where the elevation difference exceeds 21 in. (535 mm).

7.1.7.2\* Changes in level in means of egress not in excess of 21 in. (535 mm) shall be achieved either by a ramp complying with the requirements of 7.2.5 or by a stair complying with the requirements of 7.2.2.

A.7.1.7.2 Aside from the problems created for persons who are mobility impaired, small changes of elevations in floors are best avoided because of the increased occurrence of missteps where the presence of single steps, a series of steps, or a ramp is not readily apparent. Although small changes of elevation pose significant fall risks in the case of individual movement, they are even more undesirable where crowds traverse the area.

Exhibit 7.17

Simulation of walking surface user misstepping and beginning to fall. (Photo courtesy of Jake Pauls)

Exhibit 7.18

A tribometer for evaluating slip resistance. (Photo courtesy of Jake Pauls)

A contrasting marking stripe on each stepping surface can be helpful at the nosing or leading edge so that the location of each step is readily apparent, especially when viewed in descent. Such stripes should be not less than 1 in. (25 mm), but should not exceed 2 in. (51 mm), in width. Other methods could include a relatively higher level of lighting, contrasting colors, contrasting textures, highly prominent handrails, warning signs, a combination thereof, or other similar means. The construction or application of marking stripes should be such that slip resistance is consistent over the walking surface and no tripping hazard is created (*see also A.7.2.2.3.3.2*). Depending on the distractions of the surroundings, the familiarity of users with a particular small change of level, and especially the number of people that might be in a group traversing the change of level (thereby reducing visibility of the level changes), a strong argument can be made for the elimination of steps and ramps that might pose a risk of missteps.

**7.1.7.2.1** Where a ramp is used to meet the requirements of **7.1.7.2**, the presence and location of ramped portions of walkways shall be readily apparent.

**7.1.7.2.2** Where a stair is used to meet the requirements of **7.1.7.2**, the tread depth of such stair shall be not less than 13 in. (330 mm).

**7.1.7.2.3** Tread depth in industrial equipment access areas as provided in **40.2.5.3** shall be permitted.

**7.1.7.2.4** The presence and location of each step shall be readily apparent.

Prior to 1988, the *Code* prohibited stairs where changes of elevation were less than 21 in. (535 mm), because steps spanning such small elevation differences often go unnoticed and create conditions conducive to missteps. The minimum 13 in. (330 mm) tread depth and the requirement to make the presence and location of each step readily apparent were established to help reduce missteps. The text of **A.7.1.7.2** provides additional details on stair arrangement to help reduce the problem.

**Exhibit 7.19** illustrates an arrangement intended to meet the requirements of **7.1.7**. In the exhibit, tread depth has been increased over the usual minimum 11 in. (280 mm) to a minimum of 13 in. (330 mm). The leading edge of each tread has been marked to make its presence and location readily apparent.

Small elevation differences connected by ramps might also go unnoticed and create conditions conducive to missteps. **Paragraph 7.1.7.2.1** covers the hazards of trips and other missteps on ramps where such hazards are not clear to persons walking in an area where a small change of elevation is otherwise not evident. Although the consequences of a misstep are usually not as severe on ramps as on stairs, hazard mitigation is needed.

Single risers and other combinations of a few risers are considered stairs and must meet all the requirements for stairs. Because such risers are considered stairs, handrails are needed along the natural path of egress travel. In **Exhibit 7.20**, the small elevation difference is achieved by stair treads with the exaggerated depth required by **7.1.7.2.2**, complete with a handrail at one side (as required for existing stairs by **7.2.2.4.1.6**), but the patterned carpet obscures any indication of tread edge location — the stairs are not seen as separate stepping surfaces. See the second paragraph of **A.7.2.2.3.3.2**. In **Exhibit 7.21**, the small elevation difference is achieved by stair treads with the exaggerated depth required by **7.1.7.2.2**, complete with handrails at both sides (as required for new stairs by **7.2.2.4.1.1**), and the variation in tread cover striping clearly indicates the location of each tread edge.

**7.1.8\* Guards.** Guards in accordance with **7.2.2.4** shall be provided at the open sides of means of egress that exceed 30 in. (760 mm) above the floor or the finished ground level below except where guards are specifically exempted by provisions of **Chapters 11** through **43**.

**Exhibit 7.19**

*Special features for stairs involving changes in elevation of 21 in. (535 mm) or less.*

**Exhibit 7.20**

*Patterned carpet obscures any indication of tread edge location. (Photo courtesy of Jake Pauls)*

**Exhibit 7.21**

*Tread cover striping clearly indicates the location of each tread edge. (Photo courtesy of Jake Pauls)*

**A.7.1.8** Elements of the means of egress that might require protection with guards include stairs, landings, escalators, moving walks, balconies, corridors, passageways, floor or roof openings, ramps, aisles, porches, and mezzanines.

Escalators and moving walks, other than previously approved existing escalators and moving walks, are prohibited from serving as components of the required means of egress. Building occupants using the escalator at the time of fire or similar emergency must traverse some portion of the escalator to gain access to a required egress route. For those building occupants using the escalator, such travel along the escalator is part of their means of egress. The requirement that guards be provided at the open side of means of egress that exceed 30 in. (760 mm) above the floor or grade below is meant to be applied to escalators and moving walks.

The text of **A.7.1.8** reminds the user that guards need to be located at more than the open sides of stairs. Because guards have applicability to a range of locations within a building [i.e., wherever there is a vertical drop of more than 30 in. (760 mm)], the requirement for guards is located in the general provisions of **Section 7.1**. The detailed provisions for guards are found in **7.2.2** for stairs but apply for all guards, regardless of where the guards are located. **Exhibit 7.22** shows both an exit access balcony and stairs where guards are required.

**Exhibit 7.22**

*Guards at open side of exterior exit access balcony and stair.*

**7.1.9 Impediments to Egress.** Any device or alarm installed to restrict the improper use of a means of egress shall be designed and installed so that it cannot, even in case of failure, impede or prevent emergency use of such means of egress, unless otherwise provided in **7.2.1.6** and **Chapters 18, 19, 22, and 23**.

### **7.1.10 Means of Egress Reliability.**

**7.1.10.1\* Maintenance.** Means of egress shall be continuously maintained free of all obstructions or impediments to full instant use in the case of fire or other emergency.

**A.7.1.10.1** A proper means of egress allows unobstructed travel at all times. Any type of barrier including, but not limited to, the accumulations of snow and ice in those climates subject to such accumulations is an impediment to free movement in the means of egress. Another example of an obstruction or impediment to full instant use of means of egress is any security device or system that emits any medium that could obscure a means of egress. It is, however, recognized that obstructions occur on a short-duration basis. In these instances, awareness training should be provided to ensure that blockages are kept to a minimum and procedures are established for the control and monitoring of the area affected.

For a given occupancy, the combination of requirements contained in **Chapters 7 and 8** and in the corresponding occupancy chapter provides for an adequately sized and protected means of egress system. The provision in **7.1.10.1** emphasizes the importance of maintenance in keeping the egress system usable at all times. In the case of a Class A mercantile occupancy, for example, the minimum 60 in. (1525 mm) exit access aisle width required by **36.2.5.6** and **37.2.5.6** must not, subsequent to receipt of the store's occupancy permit, be filled with mid-aisle displays that reduce the aisle width. Similarly, in a business occupancy with a new exit stair of the minimum 44 in. (1120 mm) width required by **Table 7.2.2.1.2(B)**, the stair width must not be reduced by the introduction of a mechanized chairlift that is installed, for example, to comply with legislation mandating accessibility for persons with mobility impairments. (For additional guidance on the installation of stair descent devices, see **A.7.2.12.2.3**.) In an apartment building complex, the required width of the outside exit discharge sidewalk that runs along the side of the building must not be reduced by the presence of a trash dumpster on either a temporary or permanent basis.

An egress path that was code compliant when constructed might have its egress reliability compromised by human action. **Exhibit 7.23** shows a stair with flaring tread width near its base. Graspable handrails were installed along the stair flight, but the placement of potted plants prevents the stair user from accessing a handrail while traveling on the lowest three treads.

The provision of **7.1.10.1** is intended to protect against obstructions or impediments, including those that occur naturally, such as snow accumulation. **Exhibit 7.24** shows an exit door with the exterior egress path potentially impeded by snow accumulation. **Exhibit 7.25** shows a snow accumulation that, while still an impediment, does not prevent an occupant from opening the door. Following a night of freezing, the door might not be openable, even by a determined and strong occupant.

**Paragraph 7.1.10.1** does not designate responsibility for maintaining the means of egress (i.e., exit accesses, exits, and exit discharges) free and clear of obstructions. The individuals

**Exhibit 7.23**

Potted plants prevent access to required handrails. (Photo courtesy of Jake Pauls)

responsible for each facility — whether managers, owners, or operators — must make certain that the required egress components are maintained in usable condition. The authority having jurisdiction has the power to enforce this requirement.

NFPA staff has received inquiries from authorities having jurisdiction looking for requirements they could use in their efforts to enforce a ban on the introduction of artificial smoke into a building upon activation of an intrusion alarm. The intent behind the introduction of the artificial smoke is to disorient intruders and make it difficult for them to travel through the building. Emergency responders called to the building are similarly disoriented, making it dangerous to enter the building. **Paragraph 7.1.10.1**, by requiring that the means of egress be continuously maintained free of all obstructions and impediments to full instant use in case of fire or other emergency, provides authorities having jurisdiction with a tangible requirement that they can enforce to prohibit intrusion alarms from discharging smoke to obscure the egress path. Also see **4.6.1.2**, which gives the AHJ the authority to determine any requirements that are essential for the safety of building occupants that are not specifically provided for by the Code.

**Exhibit 7.24**

Snow accumulation presents potential impediment to egress. (Photo courtesy of Jake Pauls)

**Exhibit 7.25**

Snow accumulation pushed away by swinging the door open. (Photo courtesy of Jake Pauls)

### 7.1.10.2 Furnishings and Decorations in Means of Egress.

Paragraphs 7.1.10.2.1 through 7.1.10.2.3 provide guidance for the interior decoration and maintenance of buildings that serve, for example, as restaurants and theaters, where mirrored wall surfaces and excessive decoration can camouflage and, in some cases, obstruct exits. For such occupancies, care must be taken to ensure that the required, standard, well-marked exit access that leads to an unobstructed exit is not obscured in the pursuit of period or style authenticity. For example, a restaurant that is heavily decorated with red wall coverings might use green exit signs to help meet the requirements of these paragraphs, despite the fact that Chapter 7 does not specify exit sign color.

**7.1.10.2.1** No furnishings, decorations, or other objects shall obstruct exits or their access thereto, egress therefrom, or visibility thereof.

**7.1.10.2.2** No obstruction by railings, barriers, or gates shall divide the means of egress into sections appurtenant to individual rooms, apartments, or other occupied spaces. Where the authority having jurisdiction finds the required path of travel to be obstructed by furniture or other movable objects, the authority shall be permitted to require that such objects be secured out of the way or shall be permitted to require that railings or other permanent barriers be installed to protect the path of travel against encroachment.

Paragraph 7.1.10.2.2 relates to the arrangement of furniture, as well as to the arrangement of railings, gates, or barriers found in lobbies, foyers, waiting spaces, or staging areas of businesses, hospitals, health care clinics, hotels, and apartments. Because these large spaces are often subdivided by furniture (e.g., chairs, tables, and plants) or by railings and gates, furnishings must be prevented from blocking access to exits.

Paragraph 7.1.10.2.2 recommends fastening furnishings so that they are clear of access to exits or placing railings around furnishings to ensure that they are held within a fixed area and cannot be easily moved or rearranged. The Code recognizes the problem created by storage that is placed within the exit access aisles of storage rooms in mercantile occupancies, which is a violation of Code requirements. Both Chapters 36 and 37, in accordance with the provisions of 36.2.5.11(4) and 37.2.5.11(4), require an unobstructed egress path to be maintained as a specific condition for permitting egress to pass through storerooms.

**7.1.10.2.3** Mirrors shall not be placed on exit door leaves. Mirrors shall not be placed in or adjacent to any exit in such a manner as to confuse the direction of egress.

**7.1.11 Sprinkler System Installation.** Where another provision of this chapter requires an automatic sprinkler system, the sprinkler system shall be installed in accordance with the subparts of 9.7.1.1 permitted by the applicable occupancy chapters.

Paragraph 9.7.1.1 lists the three NFPA sprinkler installation standards as options for other sections of the Code to reference

where the installation of automatic sprinklers is required. Some provisions of Chapter 7 mandate the installation of sprinklers as a condition for using a particular feature. For example, the delayed-egress locking provisions of 7.2.1.6.1 require that the building be protected by either a fire detection system or an automatic sprinkler system. Yet, Chapter 7 is a core chapter that might apply to any occupancy. Thus, the requirement of 7.1.11 leaves the choice of an applicable sprinkler system installation standard to the appropriate occupancy chapter.

---

## 7.2 Means of Egress Components

Many different components of a building or structure are encountered while traversing a means of egress. These components comprise the means of egress and include such items as door assemblies, including necessary hardware; stairs and ramps, including handrails and guards; horizontal exits; exit passageways; and areas of refuge. The composition, properties, use, limits, and function of such components have an effect on the usability of the means of egress system.

Portable ladders, rope ladders, and similar devices are not recognized by the Code as providing any portion of the required capacity of a means of egress. In addition, they should not be considered in any way as an upgrade of an inadequate existing means of egress. Although such devices might be used to provide additional safety under emergency conditions, they are unreliable and can lead to a false sense of security. Such devices are often unusable by small children, older people, persons with disabilities, or those who simply have not been trained in their use. See A.7.1.1.

Changing technology and product development are responsible for the availability of supplemental evacuation equipment with features more desirable than those inherent in portable ladders, rope ladders, and similar traditional escape devices. Supplemental evacuation equipment (e.g., exterior platforms, accessed by building occupants via windows in outside walls, that travel vertically against the building walls by a cable and hoist system to carry occupants to ground level) receives no credit as satisfying any of the Code-mandated means of egress provisions. However, if a building owner voluntarily installs such a system, the Code user should implement additional safeguards to help ensure that the supplemental evacuation equipment does not interfere with use of the normal egress components, create a dangerous situation for users, or impart a false sense of security that could lead to a delay in building egress. Such safeguards are detailed in Annex B, Supplemental Evacuation Equipment.

The components of a means of egress are required to meet certain standards, be built in a prescribed manner, and perform at a level specified by the Code. Depending on whether the component is part of the access to an exit, is itself the exit, or is part of the exit discharge, the applicable requirements might differ. In

most instances, the requirements applicable to a given component are the same, regardless of where it is used within the means of egress system. For example, for new stair construction, the riser height must not exceed 7 in. (180 mm), the tread depth must be at least 11 in. (280 mm), and the handrails must be installed at both sides — regardless of where the stairs are placed within the means of egress (unenclosed exit access stairs, enclosed exit stairs, or outside exit discharge stairs).

## 7.2.1 Door Openings.

### 7.2.1.1 General.

Door assemblies serve multiple purposes that relate to the comfort and safety of building occupants and provide protection from the following:

1. Weather, drafts, noise, and disturbance from adjoining areas
2. Trespass by unauthorized persons
3. Fire and smoke, with which this *Code* is concerned

The three broad categories of door assemblies, each providing varying degrees of protection from fire and smoke, follow.

**1. Non-fire-rated door assembly.** A non-fire-rated door assembly is a door assembly such as is used in one- and two-family dwelling construction or a door assembly to a small coat closet in an office building. Although not fire rated, such door assemblies do provide a limited degree of protection, especially from smoke, if closed.

**2. Fire-rated door assembly.** A fire protection-rated door assembly is referred to as a fire door assembly. It has passed the standard fire test for door assemblies, as prescribed by NFPA 252, *Standard Methods of Fire Tests of Door Assemblies*.<sup>4</sup> During such fire testing, a fire door assembly withstands a severe fire and hose stream exposure for a given time period, which can be specified by a *Code* requirement. The fire protection rating required by the *Code* for a given application varies, depending on the uses and occupancy type involved. See [Table 8.3.4.2](#).

**3. Smoke-resisting door assembly.** A smoke-resisting door assembly might or might not have a fire protection rating. Its function is to provide a temporary barrier against the passage of heat, smoke, and gases. Some smoke-resisting door assemblies required by the *Code* must meet performance and installation criteria specified in NFPA 105, *Standard for Smoke Door Assemblies and Other Opening Protectives*.<sup>5</sup>

None of the door assemblies discussed in this commentary will perform satisfactorily if left open during a fire, thus allowing the entry of fire and combustion products into what should be a safer area than the fire area. The history of fires is full of tragic examples of those who died because of an open door assembly. There are also many examples of people saved because a door leaf was closed. Less frequent, but nonetheless tragic, are those situations in which door openings needed for escape were blocked or locked, resulting in dire consequences.

Numerous *Code* requirements, particularly those contained in [7.2.1](#), address these concerns.

Some types of door assemblies that are designed to prevent the spread of fire through wall openings for property protection purposes might be unsuitable for use in means of egress. Certain door assemblies pose the potential for entrapment if they cannot be operated or for personal injury if they are used; examples include various rolling-shutter and sliding door assemblies. However, under limited conditions, certain horizontal-sliding door assemblies are permitted to be within the exit access path. For example, [7.2.1.4.1\(7\)](#) is used by [39.2.2.2.8](#), [40.2.2.2.4](#), and [42.2.2.2.5](#) to permit existing sliding door assemblies to be positioned within the exit access path of existing business, industrial, and storage occupancies if additional criteria are met. The provisions help to ensure that the door leaf will be open when conditions in the door opening's vicinity are tenable for people movement and closed once it is no longer safe for people to seek egress via that exit access path.

See also [7.2.1.14](#) for a specialized form of sliding door assembly that has desirable life safety features.

**7.2.1.1.1** A door assembly in a means of egress shall conform to the general requirements of [Section 7.1](#) and to the special requirements of [7.2.1](#).

Wherever the *Code* refers to a fire protection-rated door assembly or fire door assembly, it is referring to the entire assembly. If any single component is not properly provided, installed, and functioning, the assembly is not a fire protection-rated assembly. For example, if a listed fire door leaf and frame are installed with positive latch and hinges but the required self-closing device is omitted, the assembly cannot be considered a fire door assembly and is not considered to have any particular fire protection rating.

**7.2.1.1.2** Every door opening and every principal entrance that is required to serve as an exit shall be designed and constructed so that the path of egress travel is obvious and direct. Windows that, because of their physical configuration or design and the materials used in their construction, have the potential to be mistaken for door openings shall be made inaccessible to the occupants by barriers or railings.

The purpose of the barriers or railings required by [7.2.1.1.2](#) is to prevent an occupant from walking through a window. Such barriers are not required to comply with the requirements of [7.2.2.4](#) applicable to guards. For example, intermediate rails or balusters spaced to meet the 4 in. (100 mm) diameter sphere requirement of [7.2.2.4.6.3](#) are not needed. A simple barrier rail, without ornamental grille-like fill or closely spaced balusters, will adequately warn occupants to avoid walking into a glass wall or large windowpane.

[Exhibit 7.26](#) shows a clear glass cross-corridor door in a hotel guest floor corridor. The circular decals on the door and glass sidelight call attention to the door positioned across the corridor egress path.

Exhibit 7.26

Circular decals that call attention to glass door in corridor egress path.

### 7.2.1.1.3 Occupied Building.

**7.2.1.1.3.1** For the purposes of [Section 7.2](#), a building shall be considered to be occupied at any time it meets any of the following criteria:

- (1) It is open for general occupancy.
- (2) It is open to the public.
- (3) It is occupied by more than 10 persons.

**7.2.1.1.3.2** Where means of egress doors are locked in a building that is not considered occupied, occupants shall not be locked beyond their control in buildings or building spaces, except for lockups in accordance with [22.4.5](#) and [23.4.5](#), detention and correctional occupancies, and health care occupancies.

Many industrial, storage, and business occupancy buildings are never open to or accessible to the public; the only occupants are employees and authorized visitors. Therefore, the term *occupied* in [7.2.1.1.3.1](#) also includes the condition of being open for general occupancy. That is, the facility is *operating or functioning*.

The intent of permitting a building with 10 or fewer occupants to be considered unoccupied — if it is not open for general occupancy and not open to the public — is to allow small security details or small cleaning crews inside a building without applying all the *Code* requirements. This will allow door assemblies to be locked and lights to be turned off without violating the *Code*. The limited number of occupants will use lights as they need them and then turn them off. In the case of security

personnel, they will carry their own lights and keys. For example, see the criterion of [7.2.1.5.5.1\(4\)](#) for making a key available to occupants, which is applicable to a special type of key-operated dead bolt lock.

The wording of [7.2.1.1.3.2](#) reiterates that it is not the intent to allow people, no matter how few the number, to be locked in a building without a ready means of egress. Even in detention and correctional facilities, where locked door assemblies are permitted, 24-hour staffing must be provided in sufficient numbers to start the release of locks necessary for emergency evacuation or rescue and initiate other necessary emergency actions within 2 minutes of alarm. See [22.7.1.1\(2\)](#) and [23.7.1.1\(2\)](#).

### 7.2.1.2 Door Leaf Width.

The title of [7.2.1.2](#) is Door Leaf Width, but, for other than the atypical case where door leaf width is specified [see [7.2.1.2.3.1](#) and, for example, [7.2.1.2.3.2\(4\)](#)], the provisions of [7.2.1.2](#) address clear width of the door opening and egress capacity width of the door opening.

Door width measurements might be used in calculating egress capacity or in determining if a minimum door width requirement is met. Depending on the purpose for which the door width measurement is used, the allowable encroachments on opening width vary. See the commentary following [7.2.1.2.1.1\(6\)](#) and [7.2.1.2.2\(4\)](#).

#### 7.2.1.2.1\* Measurement of Clear Width.

The method of measuring door width required by [7.2.1.2.1.1](#) and [7.2.1.2.1.2](#) is for meeting minimum door-opening, clear width requirements specified elsewhere in the *Code*, not for determining the egress capacity of the door opening. For example, [7.2.1.2.3.2](#) requires new door openings in means of egress to be not less than 32 in. (810 mm) in clear width, based on the need for an occupant traveling in a wheelchair to be able to move the wheelchair through the door opening, with allowance for the wheelchair user's arms and hands to guide the wheels.

**A.7.2.1.2.1** [Figure A.7.2.1.2.1\(a\)](#) and [Figure A.7.2.1.2.1\(b\)](#) illustrate the method of measuring clear width for doors.

In cases where a chapter requires a door width, for example, of not less than 36 in. (915 mm), this requirement can be met by a door leaf of the minimum specified width if the term *clear width* does not appear as part of the minimum width requirement. A pair of cross-corridor doors subject to such a requirement would be judged under the following criteria:

- (1) Each door leaf is required to be not less than 36 in. (915 mm) in width.
- (2) The pair of doors is required to provide sufficient, clear, unobstructed width (which will be less than the door leaf width measurement) to handle its assigned occupant load, based on a calculation using the appropriate egress capacity factor in [Table 7.3.3.1](#).

Figure A.7.2.1.2.1(a) Minimum Clear Width.

Figure A.7.2.1.2.1(b) Minimum Clear Width with Permitted Obstructions.

Where swinging doors do not open at least 90 degrees, the clear width of the doorway should be measured between the face of the door and the stop.

It is not the intent to regulate projections above the 6 ft 8 in. (2030 mm) height.

**7.2.1.2.1.1 Swinging Door Assemblies.** For swinging door assemblies, clear width shall be measured as follows:

- (1) The measurement shall be taken at the narrowest point in the door opening.
- (2) The measurement shall be taken between the face of the door leaf and the stop of the frame.
- (3) For new swinging door assemblies, the measurement shall be taken with the door leaf open 90 degrees.

- (4) For any existing door assembly, the measurement shall be taken with the door leaf in the fully open position.
- (5) Projections of not more than 4 in. (100 mm) into the door opening width on the hinge side shall not be considered reductions in clear width, provided that such projections are for purposes of accommodating panic hardware or fire exit hardware and are located not less than 34 in. (865 mm), and not more than 48 in. (1220 mm), above the floor.
- (6) Projections exceeding 6 ft 8 in. (2030 mm) above the floor shall not be considered reductions in clear width.

Where clear width is used to judge whether a *Code* provision for minimum door width is met, no projections into the clear width within 34 in. (865 mm) of the floor are permitted, as addressed in 7.2.1.2.1.1(5). Thus, where 7.2.1.2.3.2 requires door openings to be at least 32 in. (810 mm) in clear width, full clear width must be available near the floor to accommodate, for example, the width and height of a wheelchair and the wheelchair user's arms and hands.

At heights above 34 in. (865 mm), encroachment on clear width is permitted only on the hinge side of the door opening, and then only if the projection into the clear width does not exceed 4 in. (100 mm). Further, such projection is only for purposes of permitting panic hardware or fire exit hardware — installed in accordance with 7.2.1.7.1(2) at the minimum 34 in. (865 mm) mounting height set for new installations and the maximum mounting height of 48 in. (1220 mm) for new and existing installations — to encroach on clear width. Note, however, that projections above the floor of more than 6 ft 8 in. (2030 mm) are permitted by 7.2.1.2.1.1(6). Thus, for many door assemblies that exceed the minimum nominal height of 6 ft 8 in. (2030 mm), the projection created by a magnetic lock or hydraulic door leaf closer attached beneath the top member of the door frame is not an encroachment on door width. For door assemblies utilizing a minimum 6 ft 8 in. (2030 mm) height door frame, magnetic locks or hydraulic door leaf closers attached beneath the top member of the door frame will encroach on the space within the 6 ft 8 in. (2030 mm) vertical distance of the floor and constitute a reduction in clear width. In this case, where the minimum 6 ft 8 in. (2030 mm) height door frame is used, the concerns of the AHJ with excessive encroachment by the hydraulic leaf closer have often been allayed where the closer is mounted to the door leaf, and not suspended beneath the top member of the door frame, so as to move out of the door opening when the door leaf swings open.

Figure A.7.2.1.2.1(b) shows a 14 in. (355 mm) vertical range for mounting the panic hardware or fire exit hardware permitted by 7.2.1.2.1.1(5), with a maximum encroachment of 4 in. (100 mm) into the clear width without penalty. The 14 in. (355 mm) range is the difference between the 34 in. (865 mm) and 48 in. (1220 mm) criteria specified in 7.2.1.2.1.1(5), which are extracted from the minimum and maximum mounting heights for new panic hardware and new fire exit hardware per 7.2.1.7.1(2)(a).

The concepts described in this commentary are illustrated in Figure A.7.2.1.2.1(a) and Figure A.7.2.1.2.1(b).

**7.2.1.2.1.2 Other than Swinging Door Assemblies.** For other than swinging door assemblies, clear width shall be measured as follows:

- (1) The measurement shall be taken at the narrowest point in the door opening.
- (2) The measurement shall be taken as the door opening width when the door leaf is in the fully open position.
- (3) Projections exceeding 6 ft 8 in. (2030 mm) above the floor shall not be considered reductions in clear width.

**7.2.1.2.2\* Measurement of Egress Capacity Width.**

**A.7.2.1.2.2** Figure A.7.2.1.2.2(a) and Figure A.7.2.1.2.2(b) illustrate the method of measuring egress capacity width for purposes of calculating door egress capacity.

Figure A.7.2.1.2.2(a) Door Width — Egress Capacity.

Figure A.7.2.1.2.2(b) Door Width — Egress Capacity with Permitted Obstructions.

**7.2.1.2.2.1 Swinging Door Assemblies.** For swinging door assemblies, egress capacity width shall be measured as follows:

- (1) The measurement shall be taken at the narrowest point in the door opening.
- (2) The measurement shall be taken between the face of the door leaf and the stop of the frame.
- (3) For new swinging doors assemblies, the measurement shall be taken with the door leaf open 90 degrees.
- (4) For any existing door assembly, the measurement shall be taken with the door leaf in the fully open position.
- (5) Projections not more than 3½ in. (90 mm) at each side of the door openings at a height of not more than 38 in. (965 mm) shall not be considered reductions in egress capacity width.
- (6) Projections exceeding 6 ft 8 in. (2030 mm) above the floor shall not be considered reductions in egress capacity width.

**7.2.1.2.2.2 Other than Swinging Door Assemblies.** For other than swinging door assemblies, egress capacity width shall be measured as follows:

- (1) The measurement shall be taken at the narrowest point in the door opening.
- (2) The measurement shall be taken as the door opening width when the door leaf is in the fully open position.
- (3) Projections not more than 3½ in. (90 mm) at each side of the door openings at a height of not more than 38 in. (965 mm) shall not be considered reductions in egress capacity width.
- (4) Projections exceeding 6 ft 8 in. (2030 mm) above the floor shall not be considered reductions in egress capacity width.

The method of measuring door width required by 7.2.1.2.2.1 and 7.2.1.2.2.2 is to determine the egress capacity of the door assembly, not to meet minimum door size requirements specified elsewhere in the Code. The method of measuring door width required by 7.2.1.2.1 is for meeting minimum door-opening, clear width requirements specified elsewhere in the Code, not for determining the egress capacity of the door assembly.

The egress capacity width will be less than the door leaf width, because deductions in width are made for the stops built into the door frame and for the encroachment created by the thickness of the door leaf where its stile edge, to which the hinges are secured, extends into the door opening.

The width measurement for new door assemblies that can be opened at least 90 degrees is to be made with the door leaf open 90 degrees. Door leaves that open more than 90 degrees — permitting the stile edge of the door leaf to move out of the door opening — receive no additional width credit, based on the inability of most people to push a door leaf open more than 90 degrees prior to moving through the door opening, especially when using a door assembly with a self-closing device. Paragraph 7.2.1.2.2.1(4) exempts existing door assemblies from the 90-degree requirement. Rather, the egress capacity width

measurement for existing door assemblies is made with the door leaf in the fully open position — regardless of whether that position is less than or more than 90 degrees.

**Exhibit 7.27** depicts a new door assembly. It also might apply to an existing door assembly that opens exactly 90 degrees. The 44 in. (1120 mm) width door leaf provides approximately 40½ in. (1030 mm) of egress capacity width, measured in accordance with 7.2.1.2.2.1(1), (2), and (3). Note the reduction in egress width, as compared to the door leaf width, caused by the stop in the door frame at the left of the exhibit and the stile edge of the door leaf at the right of the exhibit.

*Egress capacity width for new door leaf open 90 degrees and for existing door leaf that opens 90 degrees.*

**Exhibit 7.28** depicts an existing door assembly for which the door leaf can be opened more than 90 degrees so that the stile edge of the door leaf moves out of the framed door opening. The 44 in. (1120 mm) width door leaf provides approximately 42 in. (1065 mm) of egress capacity width, measured in accordance with 7.2.1.2.2.1(1), (2), and (4). Note the reduction in egress width, as compared to the door leaf width, caused by the stops at each side of the door frame.

**Exhibit 7.29** depicts an existing door assembly for which the door leaf can be opened less than 90 degrees due to the presence

*Egress capacity width for existing door assembly with door leaf that opens more than 90 degrees.*

**Exhibit 7.29**

*Egress capacity width for existing door assembly with door leaf that opens less than 90 degrees.*

of a pipe column that prevents the door leaf from opening any further. The 44 in. (1120 mm) width door leaf provides approximately 38 in. (965 mm) of egress capacity width, measured in accordance with 7.2.1.2.2.1(1), (2), and (4). Note the reduction in egress width, as compared to the door leaf width, caused by the stop at the left of the exhibit and the door leaf itself as it extends into the door opening at the right of the exhibit due to the obstruction caused by the pipe column. The 38 in. (965 mm) dimension is measured in accordance with 7.2.1.2.2.1(2) to the face of the door leaf at a point where the intersection with the door leaf creates a right angle, thus ensuring that the minimum width is measured.

The wording of 7.2.1.2.2.1(5) permits projections of not more than 3½ in. (90 mm) at each side of the door opening, provided that such projections do not extend above 38 in. (965 mm) in height. For example, for a 40 in. (1015 mm) capacity width door opening, although there might be only 33 in. (840 mm) of true opening width between the projections near floor level, capacity calculations are permitted that assume an available capacity width of 40 in. (1015 mm).

The concepts described in this commentary are illustrated in [Figure A.7.2.1.2.2\(a\)](#) and [Figure A.7.2.1.2.2\(b\)](#).

### 7.2.1.2.3 Minimum Door Leaf Width.

**7.2.1.2.3.1** For purposes of determining minimum door opening width, the clear width in accordance with 7.2.1.2.1 shall be used, unless door leaf width is specified.

**7.2.1.2.3.2** Door openings in means of egress shall be not less than 32 in. (810 mm) in clear width, except under any of the following conditions:

- (1) Where a pair of door leaves is provided, one door leaf shall provide not less than a 32 in. (810 mm) clear width opening.
- (2)\* Exit access door assemblies serving a room not exceeding 70 ft<sup>2</sup> (6.5 m<sup>2</sup>) and not required to be accessible to persons with severe mobility impairments shall be not less than 24 in. (610 mm) in door leaf width.

**A.7.2.1.2.3.2(2)** An example of a room that is “not required to be accessible to persons with severe mobility impairments” is one that is not required to be accessible by *NFPA 5000*, Chapter 10.

(3)\* Door openings serving a building or portion thereof not required to be accessible to persons with severe mobility impairments shall be permitted to be 28 in. (710 mm) in door leaf width.

**A.7.2.1.2.3.2(3)** An example of a room that is “not required to be accessible to persons with severe mobility impairments” is one that is not required to be accessible by *NFPA 5000*, Chapter 10.

(4) In existing buildings, the existing door leaf width shall be not less than 28 in. (710 mm).

(5) Door openings in detention and correctional occupancies, as otherwise provided in **Chapters 22 and 23**, shall not be required to comply with **7.2.1.2.3**.

(6) Interior door openings in dwelling units as otherwise provided in **Chapter 24** shall not be required to comply with **7.2.1.2.3**.

(7) A power-operated door leaf located within a two-leaf opening shall be exempt from the minimum 32 in. (810 mm) single-leaf requirement in accordance with **7.2.1.9.1.5**.

(8) Revolving door assemblies, as provided in **7.2.1.10**, shall be exempt from the minimum 32 in. (810 mm) width requirement.

(9)\* Where a single door opening is provided for discharge from a stairway required to be a minimum of 56 in. (1420 mm) wide in accordance with **7.2.2.2.1.2**, and such door assembly serves as the sole means of exit discharge from such stairway, the clear width of the door opening, measured in accordance with **7.2.1.2.2**, shall be not less than two-thirds the required width of the stairway.

**A.7.2.1.2.3.2(9)** The relative egress carrying capacity of door openings and stairs is based on the two-to-three ratio used in **Table 7.3.3.1** to help balance the capacity of various egress elements and ensure that downstream egress facilities do not form a bottleneck or constriction to flow. For example, a stairway with a nominal width of 56 in. (1420 mm) should be served by an exit discharge door with a minimum width opening of 37 in. (940 mm) if only one discharge door is provided. It might be advantageous for two discharge doors to serve such a stairway, each with a more typical clear opening width of 32 in. (810 mm). This would facilitate access, into the exit, of fire fighters and other emergency responders without causing undue interference to evacuees attempting to transition from the stair to the exit discharge door.

Generally, various door assemblies are encountered as one travels the means of egress route. Each door opening must provide sufficient egress capacity width to accommodate the number of people expected to pass through that door opening during emergency egress as required by **Section 7.3** and must meet any

clear widths specified by other provisions of the *Code*. The egress capacity door width necessary to accommodate a specified number of persons is calculated from the occupant load served and the capacity factors applicable to level egress components, as provided in **Table 7.3.3.1**. Regardless of the occupant load served and the corresponding calculated minimum egress capacity width required, new door openings generally are not permitted to be less than 32 in. (810 mm) in clear width, as specified by the base requirement of **7.2.1.2.3.2**.

Note that a clear width of 32 in. (810 mm) permits the passage of wheelchairs; however, it might not be adequate for the normal use of the door opening for purposes other than emergency egress. Thus, door widths in excess of those required by the *Code* are often provided voluntarily for purposes of day-to-day function. Door widths in excess of the minimum specified in **7.2.1.2.3.2** often are provided where a bank of doors is needed to serve a large occupant load and the number of door assemblies is to be minimized. For example, a bank of four door assemblies, each with a 48 in. (1220 mm) door leaf, providing 15 ft (4570 mm) of clear width and capacity for 900 persons, might be used in place of a bank of six door assemblies, each with a 34 in. (865 mm) door leaf, providing 15 ft (4570 mm) of clear width and capacity for 900 persons.

If a door assembly in a new business occupancy is to serve 120 occupants, for example, the minimum egress capacity door width calculated from the perspective of occupant load served would be 24 in. (610 mm) [i.e., calculated as 120 persons  $\times$  0.2 in./person (120 persons  $\times$  5 mm/person) — see **7.3.3.1**]. However, a door opening providing only 24 in. (610 mm) of egress capacity width would not satisfy **7.2.1.2.3.2**, which requires that, as a minimum, the door opening must provide 32 in. (810 mm) of clear width. Because more than one requirement affects door width, a comparison must be made between the calculated minimum width for egress capacity purposes and the more arbitrary minimum width requirement of **7.2.1.2.3.2**. Having performed the comparison, the greater width — in this case, 32 in. (810 mm) — must be used.

Where another *Code* section specifies a minimum door width greater than 32 in. (810 mm), the greater width must be provided. Generally, the greater width is specified in terms of clear width. For example, in new health care occupancies, the minimum width for patient room door openings and cross-corridor door openings is 41½ in. (1055 mm) in clear width [see **18.2.3.6(1)**]. The 41½ in. (1055 mm) minimum clear width requirement unintentionally connotes a precision and accuracy that one might expect resulted from a detailed research program; in reality, it represents an attempt to quantify the clear width realized when a typical 44 in. (1120 mm) wide door leaf is swung to its 90-degree open position. For many editions of the *Code*, new health care occupancies specified the required minimum as 44 in. (1120 mm) of door leaf width, not 41½ in. (1055 mm) of clear opening.

The exemptions of **7.2.1.2.3.2(1)** through (8) modify the minimum 32 in. (810 mm) clear width requirement so as to recognize

smaller door opening widths for the specific situations they address. The provision addressed by 7.2.1.2.3.2(9) is not an exemption to the 32 in. (810 mm) clear width criterion but is an additional requirement. Commentary on this provision follows.

Paragraph 7.2.1.2.3.2(1) exempts one of the door leaves used in a pair of door leaves from the 32 in. (810 mm) clear width criterion, because the minimum 32 in. (810 mm) clear width opening provided by the other door leaf can serve to accommodate a wheelchair user.

Paragraph 7.2.1.2.3.2(2) permits a small room, likely occupied by only a couple of people and not required to be accessible to people with severe mobility impairments, to use a 24 in. (610 mm) width door assembly. This exemption does not specify clear width, so a minimum 24 in. (610 mm) wide door leaf would be sufficient. The annex text of A.7.2.1.2.3.2(2) provides guidance on determining what constitutes a room that is not required to be accessible to persons with severe mobility impairments.

Paragraph 7.2.1.2.3.2(3) also addresses door assemblies serving spaces not required to be accessible to people with severe mobility impairments. In lieu of a room size, the exemption can be applied, regardless of occupant load, but the door leaf width must be at least 28 in. (710 mm). The annex text of A.7.2.1.2.3.2(3) provides guidance on determining what constitutes a room that is not required to be accessible to persons with severe mobility impairments.

Earlier editions of the *Code* specified that no single door leaf in a door opening was permitted to be less than 28 in. (710 mm) wide. To prevent automatically creating a situation of noncompliance where there had previously been compliance, 7.2.1.2.3.2(4) exempts existing buildings from the minimum 32 in. (810 mm) clear width requirement if the door width (i.e., the leaf width) is at least 28 in. (710 mm).

For security and operations purposes, 7.2.1.2.3.2(5) permits detention and correctional facilities to have door assemblies of smaller width. See Chapters 22 and 23.

Chapter 24 establishes that door assemblies within dwelling units are within the means of escape and not the means of egress. Paragraphs 24.2.4.1 and 24.2.4.2 permit such door assemblies, whether new or existing, to be a minimum of 28 in. (710 mm) in leaf width and, in some cases, 24 in. (610 mm). Paragraph 7.2.1.2.3.2(6) recognizes this permission.

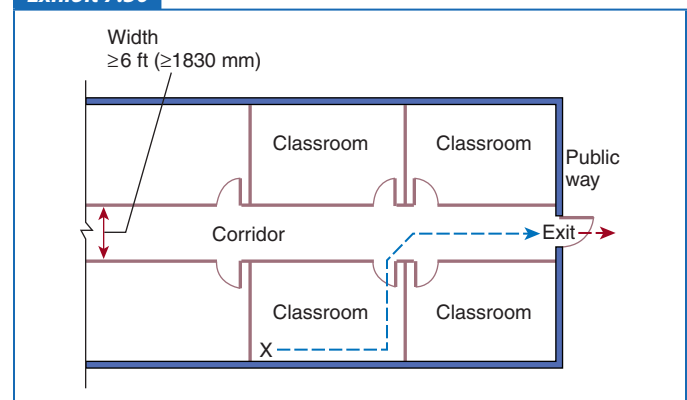

The provision of 7.2.1.2.3.2(9) relates to minimum stair criteria in 7.2.2. The stair provisions of 7.2.2.2.1.2 require extra stair width for buildings, such as high-rise buildings, where it is expected that occupants will still be in the process of egressing the building when emergency responders, such as fire fighters, arrive. The extra stair width helps to facilitate counterflow — the downward movement of building occupants that occurs while emergency responders are simultaneously moving up the same stairs — and allows faster stair travel by building occupants.

The provision of 7.2.1.2.3.2(9) requires the single door assembly from the stair enclosure to the exit discharge to be sized so that occupants do not need to queue on the stairs while waiting for their turn to move through the door opening. The

two-to-three ratio of door-opening width to stair width is consistent with the capacity factors of Table 7.3.3.1, that is, 0.2 in. (5 mm) per person for level travel, such as that through door openings, and 0.3 in. (7.6 mm) per person for stair travel. The two-to-three ratio is further explained in A.7.2.1.2.3.2(9).

It is the intent of the *Code* that a door opening not create a bottleneck in the means of egress. At times, another component of the means of egress might be larger than required, creating the illusion of a bottleneck at an appropriately sized door opening. However, a door opening with a width that is adequate for the occupant load served and with at least a 32 in. (810 mm) clear width is sufficient for other than the special case addressed by 7.2.1.2.3.2(9). A door opening serving a hallway often is not as wide as the hallway. This is illustrated in Exhibit 7.30. Because operational features of the occupancy, in addition to the occupant load, are considered in determining needed corridor width, the corridor might be wider than the exit door opening serving the corridor. In Exhibit 7.30, which depicts a new school, the corridor is required by 14.2.3.2 to be 6 ft (1830 mm) wide, as a minimum, and wider only if that section of corridor serves more than 360 persons [i.e., based on a calculation using the capacity factor of 0.2 in. (5 mm) per person for level travel from Table 7.3.3.1]. The exit door opening is required by 7.2.1.2.3.2 to be 32 in. (810 mm) wide, as a minimum, and wider only if it serves more than 160 persons (again, based on a calculation using the capacity factor for level travel).

Exhibit 7.30

Exit door-opening width and corridor width relationship.

In a health care occupancy, the corridor and door opening widths are usually much wider than the occupant load dictates. In this instance, the sizes of the corridor and door openings are governed by the necessity to move patients on gurneys. Patients are often connected to medical equipment that must be moved with the patients along the means of egress route.

Note that, since the 1997 edition, the *Code* no longer restricts door leaf width to a maximum of 48 in. (1220 mm). Provided that the door leaf and its hardware are maintained in good working order, there is insufficient reason to limit the maximum width of a door leaf.

### 7.2.1.3 Floor Level.

**7.2.1.3.1** The elevation of the floor surfaces on both sides of a door opening shall not vary by more than ½ in. (13 mm), unless otherwise permitted by 7.2.1.3.5, 7.2.1.3.6, or 7.2.1.3.7.

**7.2.1.3.2** The elevation of the floor surfaces required by 7.2.1.3.1 shall be maintained on both sides of the door openings for a distance not less than the width of the widest leaf.

**7.2.1.3.3** Thresholds at door openings shall not exceed ½ in. (13 mm) in height.

**7.2.1.3.4** Raised thresholds and floor level changes in excess of ¼ in. (6.3 mm) at door openings shall be beveled with a slope not steeper than 1 in 2.

**7.2.1.3.5** In existing buildings, where the door opening discharges to the outside or to an exterior balcony or exterior exit access, the floor level outside the door opening shall be permitted to be one step lower than that of the inside, but shall be not more than 8 in. (205 mm) lower.

**7.2.1.3.6** In existing buildings, a door assembly at the top of a stair shall be permitted to open directly at a stair, provided that the door leaf does not swing over the stair and that the door opening serves an area with an occupant load of fewer than 50 persons.

**7.2.1.3.7** Where doors serve spaces that are not normally occupied, the floor level shall be permitted to be lower than that of the door opening but shall be not more than 8 in. (205 mm) lower.

The detailed dimensional tolerances specified for thresholds at door openings are intended to permit persons in wheelchairs, persons using assistive mobility devices such as walkers, and those with difficulty lifting their feet to move easily through those openings. Arrangements meeting the criteria useful to persons with disabilities provide for the safe use of door assemblies by other occupants.

In earlier editions, the Code permitted the floor level outside exterior door assemblies to be one step — up to 8 in. (205 mm) — lower than the floor level inside the door opening. This was permitted to avoid blocking the outward swing of the door leaf by a buildup of snow or ice. The requirements of 7.2.1.3.1 are practical for new construction because of the importance of avoiding tripping hazards, and because other provisions of the Code require that the means of egress be maintained free of obstructions and protected from the weather, thus providing for the removal of snow or ice accumulations. Existing buildings continue to be permitted to use one exterior step. See 7.2.1.3.5.

Exhibit 7.31 shows an exterior door landing with a depth much less than the width of the door leaf. The undersized landing presents an almost immediate step-down upon moving from the inside of the building to the outside. The arrangement does not meet the requirement of 7.2.1.3.2 but might be judged by the AHJ as being not worse than an immediate step down as

Exhibit 7.31

*Exterior landing deficient in depth, creating an almost immediate step down at the door opening. (Photo courtesy of Jake Pauls)*

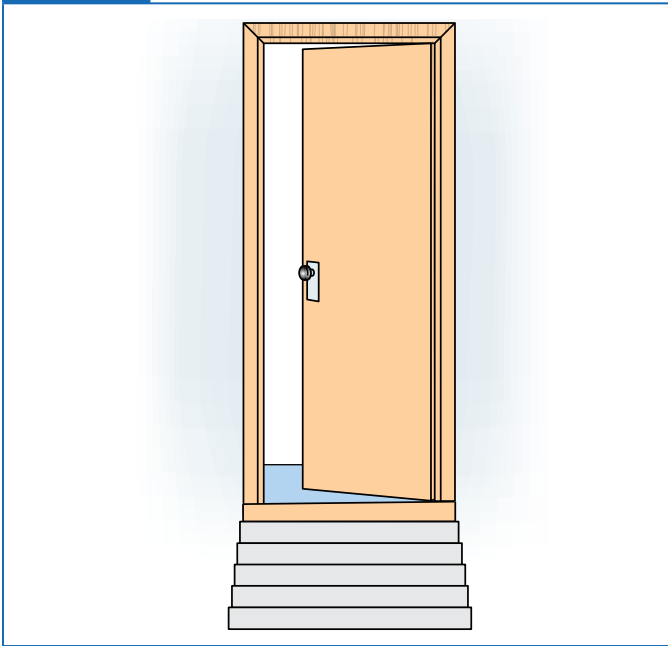

permitted by 7.2.1.3.5 for existing situations. Note that the presence of the step-down is marked in cautionary yellow paint.

Paragraph 7.2.1.3.6 recognizes an existing situation in which the door leaf of a door assembly at the top of a stair opens directly at the stair without providing a level landing on the stair side of the door opening. In this case, however, the door leaf swings away from the stair, rather than swinging over the stair. See Exhibit 7.32. This situation is permitted in existing buildings where the area served by the door assembly has an occupant load of fewer than 50 persons. Paragraph 7.2.2.3.2.5 permits this situation as an exemption to the requirement of 7.2.2.3.2 that there be a level landing on each side of the door opening that is at least as deep in the direction of stair run as the door leaf is wide. The wording of 7.2.1.3.6 and 7.2.2.3.2.5 is, for application purposes, virtually identical. The dual placement of the exemption is helpful to Code users. One user might see the issue as being related to doors and seek guidance via the provisions of 7.2.1, while another user might see the issue as being related to stairs and seek guidance via the provisions of 7.2.2.

The exemption permitted by 7.2.1.3.6 does not permit the dangerous practice of swinging the door leaf out over the stair, because it would force a person climbing the stairs to reach for the doorknob and back away by descending to a tread located a riser or two lower in order to pull the door leaf open while attempting to maintain stability on the stair. Neither does the exemption permit another dangerous practice of opening a door leaf directly at the bottom of a stair without providing a

Exhibit 7.32

Door leaf opening directly at the top of a stair, but not swinging over the stair.

level landing on the stair side of the door opening. Such an action would force a person descending the stair to lean forward and downward to reach the latch release and then push the door leaf open while standing on a tread located one or more risers above the base of the door opening and attempting to maintain stability on the stair.

The provision of 7.2.1.3.7 is new for the 2015 edition of the Code. It permits a maximum 8 in. (205 mm) elevation difference between the door opening and the floor, where the door serves a space that is normally unoccupied. The exemption can be used for new construction or existing situations. The elevation difference between the door opening and the floor can occur at one or both sides of the door opening. Where the elevation difference between the door opening and the floor occurs at both sides of the door opening, the arrangement is similar to that encountered on a ship at a door opening in a bulkhead. This arrangement is depicted in Exhibit 7.33.

#### 7.2.1.4 Swing and Force to Open.

**7.2.1.4.1\* Swinging-Type Door Assembly Requirement.** Any door assembly in a means of egress shall be of the side-hinged or pivoted-swinging type, and shall be installed to be capable of swinging from any position to the full required width of the opening in which it is installed, unless otherwise specified as follows:

- (1) Door assemblies in dwelling units, as provided in Chapter 24, shall be permitted.

Exhibit 7.33

Elevation difference between floor and door leaf opening to a normally unoccupied room.

- (2) Door assemblies in residential board and care occupancies, as provided in Chapters 32 and 33, shall be permitted.
- (3) Where permitted in Chapters 11 through 43, horizontal-sliding or vertical-rolling security grilles or door assemblies that are part of the required means of egress shall be permitted, provided that all of the following criteria are met:
  - (a) Such grilles or door assemblies shall remain secured in the fully open position during the period of occupancy by the general public.
  - (b) On or adjacent to the grille or door opening, there shall be a readily visible, durable sign in letters not less than 1 in. (25 mm) high on a contrasting background that reads as follows: THIS DOOR TO REMAIN OPEN WHEN THE SPACE IS OCCUPIED.
  - (c) Door leaves or grilles shall not be brought to the closed position when the space is occupied.
  - (d) Door leaves or grilles shall be operable from within the space without the use of any special knowledge or effort.
  - (e) Where two or more means of egress are required, not more than half of the means of egress shall be equipped with horizontal-sliding or vertical-rolling grilles or door assemblies.
- (4) Horizontal-sliding door assemblies shall be permitted under any of the following conditions:
  - (a) Horizontal-sliding door assemblies in detention and correctional occupancies, as provided in Chapters 22 and 23, shall be permitted.
  - (b) Special-purpose horizontally sliding accordion or folding door assemblies complying with 7.2.1.14 shall be permitted.

- (c) Unless prohibited by **Chapters 11** through **43**, horizontal-sliding door assemblies serving a room or area with an occupant load of fewer than 10 shall be permitted, provided that all of the following criteria are met:
- The area served by the door assembly has no high hazard contents.
  - The door assembly is readily operable from either side without special knowledge or effort.
  - The force required to operate the door assembly in the direction of door leaf travel is not more than 30 lbf (133 N) to set the door leaf in motion and is not more than 15 lbf (67 N) to close the door assembly or open it to the minimum required width.
  - The door assembly complies with any required fire protection rating, and, where rated, is self-closing or automatic-closing by means of smoke detection in accordance with **7.2.1.8** and is installed in accordance with NFPA 80, *Standard for Fire Doors and Other Opening Protectives*.
  - Corridor door assemblies required to be self-latching have a latch or other mechanism that ensures that the door leaf will not rebound into a partially open position if forcefully closed.
- (d) Where private garages, business areas, industrial areas, and storage areas with an occupant load not exceeding 10 contain only low or ordinary hazard contents, door openings to such areas and private garages shall be permitted to be horizontal-sliding door assemblies.
- (5) Where private garages, business areas, industrial areas, and storage areas with an occupant load not exceeding 10 contain only low or ordinary hazard contents, door openings to such areas and private garages shall be permitted to be vertical-rolling door assemblies.
- (6) Revolving door assemblies complying with **7.2.1.10** shall be permitted.
- (7) Existing fusible link–operated horizontal-sliding or vertical-rolling fire door assemblies shall be permitted to be used as provided in **Chapters 39, 40, and 42**.

**Paragraph 7.2.1.4.1** requires that door assemblies within the means of egress be of the side-hinged or pivoted-swinging type. A pivoted-swinging door does not have hinges connecting the hinge stile edge of the door to the side of the door frame. Instead, pins inserted into the top and bottom of the door leaf, a short distance from the hinge stile edge, create the pivot point on which the door leaf swings. A pivoted swinging door is shown in **Exhibit 7.34**. Side-hinged and pivoted-swinging types of door assemblies are most familiar to the general public, and their operation is readily understood.

Furthermore, **7.2.1.4.1** requires that the door leaf be capable of swinging to the full required width of the opening. The required width is determined by two width considerations. The first consideration involves the width required for egress capacity purposes. For example, if a door assembly in a business

**Exhibit 7.34**

A pivoted swinging door.

occupancy needs to accommodate 180 persons, the applicable capacity factor from **Table 7.3.3.1** dictates that the door opening provide a 36 in. (915 mm) egress capacity width [i.e., calculated as 180 persons  $\times$  0.2 in./person (180 persons  $\times$  5 mm/person)]. The second consideration involves the minimum clear width required, regardless of occupant load served. For the same business occupancy, the minimum clear width is specified in **7.2.1.2.3.2** as 32 in. (810 mm). The required width is the larger of the two widths — in this example, the 36 in. (915 mm) calculated from the egress capacity consideration.

**Paragraphs 7.2.1.4.1(1)** and **(2)** recognize that some occupancy chapters provide exemptions to the requirement that door assemblies be of the side-hinged or pivoted-swinging type. **Chapters 24, 32, and 33**, which apply to one- and two-family dwellings and residential board and care occupancies, do not require that door leaves be of the swinging type. These exemptions recognize the smaller numbers of persons using door assemblies within dwellings and the familiarity those occupants have with the operation of other door assembly types, such as sliding door assemblies.

**Paragraph 7.2.1.4.1(3)** permits horizontal-sliding or vertical-rolling security grilles or door assemblies to be used in lieu of side-hinged- or pivoted-swinging-type door assemblies, provided that the exemption is specifically permitted by the applicable occupancy chapter. This exemption permits the type of security door assemblies and grilles normally found in mall buildings.

Note that there is a difference between 7.2.1.4.1(3)(a) and 7.2.1.4.1(3)(c). Paragraph 7.2.1.4.1(3)(a) requires that the door assembly be fully open when the public occupies the space, while 7.2.1.4.1(3)(c) states that the grille or door leaf cannot be closed when the space is occupied. This allows the common practice of leaving the grille or door leaf partially closed at closing time and other times when restricting entry to the general public is desired. See the explanation of the term *occupied* in 7.2.1.1.3 and its commentary.

The following occupancies permit the use of horizontal-sliding or vertical-rolling door assemblies complying with 7.2.1.4.1(3). See the referenced paragraphs for additional restrictions, if any, imposed by the occupancy chapter:

1. Assembly occupancies (12.2.2.2.2, 13.2.2.2.2)
2. Mercantile occupancies (36.2.2.2.7, 37.2.2.2.7)
3. Business occupancies (38.2.2.2.7, 39.2.2.2.7)

As referenced in 7.2.1.4.1(4)(a), detention and correctional occupancies permit certain sliding door assemblies, because swinging door leaves can become readily accessible weapons for use by residents against staff.

Paragraph 7.2.1.4.1(4)(b) recognizes the use of a special-purpose horizontally sliding accordion or folding door assembly under detailed conditions. One of the characteristic features of this door assembly is its operability in the direction of door leaf travel when a specified force is applied in the direction of occupant travel. See also 7.2.1.14.

Paragraph 7.2.1.4.1(4)(c) was new to the 2009 edition of the Code and expanded a provision that applied only to horizontal-sliding door assemblies in health care occupancies. The provision recognizes horizontal-sliding door assemblies serving fewer than 10 persons in any occupancy, unless an occupancy chapter specifically prohibits use of the provision. See the detailed criteria in 7.2.1.4.1(4)(c)i. through 7.2.1.4.1(4)(c)v.

Paragraphs 7.2.1.4.1(4)(d) and 7.2.1.4.1(5) recognize that many private garages, small businesses, and industrial and storage buildings typically have only vertical-rolling or horizontal-sliding door assemblies and no side-hinged door assemblies. Provided that the maximum 10-person occupant load is not exceeded and there are no high hazard contents, such door assemblies are permitted to substitute for side-hinged or pivoted-swinging door assemblies.

Paragraph 7.2.1.4.1(6) cross-references the provisions of 7.2.1.10, which apply to revolving door assemblies. If 7.2.1.4.1(6) did not exist, it might be assumed, incorrectly, that revolving door assemblies violate the requirement for door assemblies to be side-hinged or pivoted-swinging.

Paragraph 7.2.1.4.1(7) legitimizes the provisions of 39.2.2.2.8, 40.2.2.2.4, and 42.2.2.2.5 that permit existing fusible link-operated sliding door assemblies to be positioned within the exit access of existing business, industrial, and storage occupancies if additional criteria are met. These provisions help to ensure that the door leaf is open when conditions in the door opening's vicinity are tenable

for occupant movement and that it is closed once it is no longer safe for persons to seek egress via that exit access path.

**A.7.2.1.4.1** Where doors are subject to two-way traffic, or where their opening can interfere with pedestrian traffic, an appropriately located vision panel can reduce the chance of accidents.

Swinging doors in horizontal- or vertical-rolling partitions should be permitted in a means of egress where the following criteria are met:

- (1) The door or doors comply with 7.2.1.4.
- (2) The partition in which the doors are mounted complies with the applicable fire protection rating and closes upon smoke detection or power failure at a speed not exceeding 9 in./s (230 mm/s) and not less than 6 in./s (150 mm/s).
- (3) The doors mounted in the partition are self-closing or automatic-closing in accordance with 7.2.1.8.

**7.2.1.4.2 Door Leaf Swing Direction.** Door leaves required to be of the side-hinged or pivoted-swinging type shall swing in the direction of egress travel under any of the following conditions:

- (1) Where serving a room or area with an occupant load of 50 or more, except under any of the following conditions:
  - (a) Door leaves in horizontal exits shall not be required to swing in the direction of egress travel where permitted by 7.2.4.3.8.1 or 7.2.4.3.8.2.
  - (b) Door leaves in smoke barriers shall not be required to swing in the direction of egress travel in existing health care occupancies, as provided in Chapter 19.
- (2) Where the door assembly is used in an exit enclosure, unless the door opening serves an individual living unit that opens directly into an exit enclosure
- (3) Where the door opening serves a high hazard contents area

The provisions regulating the direction of door leaf swing appear in 7.2.1.4.2 and 7.2.4.3.8(1).

Paragraph 7.2.1.4.2(1) requires all door leaves serving in the means of egress from a room or area with an occupant load of 50 or more persons to swing in the direction of egress travel. For example, if the occupant load of a room with two exit access door assemblies is 80 persons, the door leaves of both door assemblies are required to swing in the direction of egress travel. The 50-person criterion is not related to the number of persons expected to use a given door opening but, rather, to the total occupant load of the room. Therefore, it would be incorrect in the case of this 80-person example to claim that 40 persons will move to each of the two door openings, that the 40-person number is fewer than the 50-person threshold, and that neither door leaf needs to swing in the direction of egress travel. The fact that the total occupant load of the room is more than 50 persons is sufficient condition to require the exit access door leaves to swing in the direction of egress travel.

Paragraph 7.2.1.4.2(2) requires a door leaf used in an exit enclosure to swing in the direction of egress travel. An example

of a door leaf used in an exit enclosure is the door leaf in the opening between an exit access corridor and an enclosed exit stair. The main entrance and exit door leaf from an office building lobby to the outside is not a door leaf used in an exit enclosure, although it is an exit door. Door leaf swing direction for such a door would be regulated by the 50-person criterion of 7.2.1.4.2(1).

Paragraph 7.2.1.4.2(3) requires a door leaf serving a high hazard contents area to swing in the direction of egress travel. Persons leaving high hazard contents spaces under fire or similar emergency must not be impeded, as would occur if they had to stop and pull a door toward them before egressing the space.

Paragraph 7.2.4.3.8(1) requires a swinging fire door assembly used in a horizontal exit to swing in the direction of egress travel.

If none of the requirements of 7.2.1.4.2(1) through (3), or 7.2.4.3.8(1) applies, a door leaf is permitted to swing against the direction of egress travel.

Ideally, all door leaves in a means of egress would swing in the direction of egress travel. However, because of operational concerns, there are cases where door leaf swing in the direction of egress travel is not desirable. For example, a classroom door leaf that swings into a corridor serving as an exit access for several classrooms might open against another door leaf or against the flow of people and possibly restrict the width available as corridor exit access. The Code recognizes this danger and permits the classroom/corridor door leaf from a room with an occupant load of fewer than 50 persons to swing against the direction of egress travel. This provision limits the number of people using a door opening whose door leaf swings against egress travel to that which is safe. The Code also recognizes similar constraints with regard to an exterior exit door assembly; although such a door assembly is considered an exit but not within an exit enclosure, the Code does not require that it swing in the direction of egress travel, unless it serves 50 or more occupants.

Exhibit 7.35 illustrates considerations involved in evaluating door leaf swing direction as addressed in 7.2.1.4.2. Door assembly C is permitted to swing back into the room if the room has an occupant load of fewer than 50 persons and does not have high hazard contents [see 7.2.1.4.2(1) and (3)]. Door assembly D must swing in the direction of egress travel if the room has an occupant load of 50 or more [see 7.2.1.4.2(1)]. Door assembly E, although it is an exit door assembly, is not used in an exit enclosure [see 7.2.1.4.2(2)], so its door leaf is permitted to swing back into the room if the occupant load is fewer than 50 and the room does not have high hazard contents. Door assemblies A and B are related to the encroachment-related provisions of 7.2.1.4.3. They open into the corridor directly opposite each other. Although this does not violate any Code provision, it is preferable that door leaves do not swing in a direction that blocks the use of the corridor when both are open.

Paragraph 7.2.1.4.2(1)(a) recognizes that the provisions of 7.2.4.3.8.1 exempt door leaves in horizontal exits from having to swing in the direction of egress travel in accordance with specific

Exhibit 7.35

Door leaf swing direction considerations.

allowances and conditions for existing health care occupancies and existing detention and correctional occupancies. For these occupancies, staff is expected to be able to control occupant movement at horizontal exit door assemblies to prevent a crowd from pushing against a door leaf that is arranged to open only by swinging back toward the occupants. See 7.2.4.3.8.1. Also see 7.2.4.3.8.2 for an exemption with applicability to any occupancy that recognizes the impracticality of replacing an existing horizontal exit door leaf with a pair of door leaves where the corridor does not have sufficient width to accommodate the pair.

Paragraph 7.2.1.4.2(1)(b) exempts smoke barrier door assemblies from having to swing in the direction of egress travel in existing health care facilities. Such door assemblies usually span the width of a corridor. Because existing health care occupancies are permitted to have corridors as narrow as 48 in. (1220 mm), it might be impractical to install a pair of door leaves swinging in opposite directions. The single door leaf recognized by the exception swings in the correct direction for occupants on one side and swings against the direction of egress travel for occupants on the other side. Because staff directs the egress or relocation movement necessary during an emergency, the direction of door leaf swing problem is alleviated.

The exemption offered by 7.2.1.4.2(2) addresses the common design in apartment buildings in which door assemblies from the exit enclosure into apartment units normally swing into the apartment units. This design is common in a three-story, single-exit garden apartment. The swing of the door leaf in this arrangement is not a significant concern. The exemption also addresses another situation common to hotels where guest room door assemblies frequently open directly into an exit enclosure created to enclose a formerly open stair. Because it is often necessary to use part of the corridor to create a stair

landing for the newly enclosed exit stair, the exemption offers some relief without compromising safety.

Per 7.2.1.4.2(3), door leaves to hazardous contents areas must swing in the direction of egress travel. A conflict sometimes arises between this requirement and the desire of those responsible for explosion control — who prefer that door leaves to areas subject to explosion be required to swing inward to impede spreading the effects of a blast to adjacent rooms and spaces. In new construction, this conflict can usually be resolved if the hazardous contents area can be located along an outside wall of the main building; the required egress door assemblies then open directly to the outside — which is desirable for life safety. This arrangement is also favorable for explosion relief, because it easily allows the door leaves to swing outward. In existing situations, or where the hazardous area must be located internal to a building and away from exterior walls, the conflict is not easily resolved. The AHJ needs to work with the building owner, insurer, and other involved parties to determine how best to reduce the exposure hazard while adequately providing needed life safety to those who work in the hazardous area. See also Section 7.11.

#### 7.2.1.4.3\* Door Leaf Encroachment.

**A.7.2.1.4.3** The requirements of 7.2.1.4.3 are not intended to apply to the swing of cross-corridor doors, such as smoke barrier doors and horizontal exits. Neither are the requirements intended to apply to doors from rooms that are typically unoccupied, such as janitor's closets, electrical closets, or telecommunications closets.

**7.2.1.4.3.1** During its swing, any door leaf in a means of egress shall leave not less than one-half of the required width of an aisle, a corridor, a passageway, or a landing unobstructed, unless both of the following conditions are met:

- (1) The door opening provides access to a stair in an existing building.
- (2) The door opening meets the requirement of 7.2.1.4.3.2.

**7.2.1.4.3.2** When fully open, any door leaf in a means of egress shall not project more than 7 in. (180 mm) into the required width of an aisle, a corridor, a passageway, or a landing, unless the door leaf is equipped with an approved self-closing device and is not required by the provisions of 7.2.1.4.2 to swing in the direction of egress travel.

Door leaves capable of swinging a full 180 degrees, so that they rest nearly flat against the wall in which the door opening is installed, have a greater utility than door leaves capable of swinging only 90 degrees. The 180-degree-swinging door leaf can be fully opened into a corridor without significant intrusion on corridor width. The 90-degree-swinging door leaf, however, might have to open into an unusually wide corridor, be set into an alcove, or otherwise be recessed so as not to exceed the maximum encroachment permitted by 7.2.1.4.3.1.

Note that 7.2.1.4.3.1 requires that, during its swing, a door leaf must leave unobstructed at least one-half of the required

width of a corridor. Note that this requirement is concerned with the required corridor width, which is not necessarily the same as the actual width. For example, in a corridor that is required to be 44 in. (1120 mm) wide but that is voluntarily constructed to be 56 in. (1420 mm) wide, a 34 in. (865 mm) wide door leaf — a door leaf that provides the minimum 32 in. (810 mm) clear width required by 7.2.1.2.3.2 — would swing to encroach on 34 in. (865 mm) of the corridor width. Although this encroachment is more than one-half of the actual corridor width, it does leave one-half of the required corridor width [22 in. (560 mm)] unobstructed. Such an arrangement meets the requirement of 7.2.1.4.3.1.

Door leaves that swing within a recessed pocket of the corridor, so as not to protrude into the required corridor width, provide the best arrangement for clear passage through an exit access corridor. Exhibit 7.36 shows a school classroom door swinging into a recessed pocket in the corridor. Door leaves that swing 180 degrees so that they come to rest against a wall and do not extend into more than 7 in. (180 mm) of required corridor width provide an acceptable arrangement in accordance with 7.2.1.4.3.2. A door leaf that swings 90 degrees so that it comes to rest in the path of travel is considered not to encroach excessively on the exit access corridor width if not more than 7 in. (180 mm) of the required width of the corridor remains obstructed. See Exhibit 7.37.

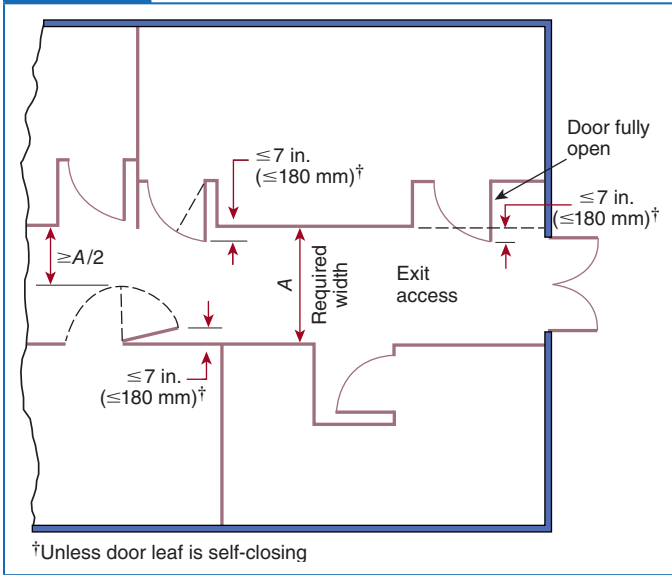

A self-closing door leaf is not subject to the maximum 7 in. (180 mm) encroachment provision of 7.2.1.4.3.2. Exhibit 7.38 depicts a self-closing door leaf as exempted by 7.2.1.4.3.2 from

**Exhibit 7.36**

*Classroom door swinging into recessed pocket in corridor.*

Exhibit 7.37

Door leaf swing into a corridor.

Exhibit 7.38

Self-closing door leaf exempt from maximum 7 in (180 mm) encroachment provision.

the maximum 7 in. (180 mm) encroachment provision. However, the door leaf is subject to the provision of 7.2.1.4.3.1 relative to maintaining at least half the required width of the corridor unencumbered by the swinging door leaf.

Door leaves of door assemblies serving as an entrance into an enclosed stair must not unduly block the stair landing or the stairs. Ideally, the door leaf should not reduce the required width either during its swing or while at rest. However, the Code does permit encroachment on the stair landing, as shown in Exhibit 7.39. For most stairs, Table 7.2.2.1.2(B) requires a 44 in. (1120 mm) clear width. In cases such as these, the  $B \geq A/2$  rule shown in Exhibit 7.39 requires that the clearance between the leading edge of the opening door leaf and stair newel post be at least 22 in. (560 mm). However, where the total occupant load of all floors served by the stair is fewer than 50 persons, 7.2.2.1.2(A) permits a 36 in. (915 mm) wide stair; in this case, the  $B \geq A/2$  rule requires that the clearance between the leading edge of the opening door leaf and stair newel post be at least 18 in. (455 mm).

An acceptable arrangement for a door leaf opening onto a stair landing in an existing building is shown in Exhibit 7.40. In

Exhibit 7.39

Minimum required unobstructed clearance with door leaf encroaching on landing in new buildings.

Exhibit 7.40

Encroachment during door leaf swing not limited in existing buildings.

lieu of a  $B \geq A/2$  rule, existing stairs are not required to maintain a specified clearance between the leading edge of the opening door leaf and stair newel post.

**7.2.1.4.3.3** Surface-mounted latch release hardware on the door leaf shall be exempt from being included in the maximum 7 in. (180 mm) projection requirement of 7.2.1.4.3.1, provided that both of the following criteria are met:

- (1) The hardware is mounted to the side of the door leaf that faces the aisle, corridor, passageway, or landing when the door leaf is in the open position.
- (2) The hardware is mounted not less than 34 in. (865 mm), and not more than 48 in. (1220 mm), above the floor.

The provision of 7.2.1.4.3.3 specifies that latch release hardware that is surface mounted to the side of the door leaf that faces the aisle, corridor, passageway, or landing when the door leaf is in the open position is exempted from inclusion in the maximum 7 in. (180 mm) projection specified in 7.2.1.4.3.1, provided that such hardware is mounted 34 in. to 48 in. (865 mm to 1220 mm) above the floor. The hardware on the back side of the door leaf is counted in the maximum 7 in. (180 mm) projection, but the hardware on the side of the door leaf that faces the landing is not. The provision is consistent with the door-opening clear width encroachment criteria of 7.2.1.2.1.1(5) as depicted in Figure A.7.2.1.2.1(b). This provision helps to alleviate the problem where the AHJ cites the door leaf encroachment as excessive because of the latch release hardware that protrudes into the egress path. Wheelchair users are able to travel past the door without being encumbered, as the hardware must be at least 34 in. (865 mm) off the floor.

**7.2.1.4.4 Screen Door Assemblies and Storm Door Assemblies.** Screen door assemblies and storm door assemblies used in a means of egress shall be subject to the requirements for direction of swing that are applicable to other door assemblies used in a means of egress.

Various functional arrangements of screen or storm door assemblies can be provided without allowing a door leaf to swing against the direction of egress travel. A screen or storm door assembly might be permitted to be used in proximity to a door opening with an ordinary door assembly by providing a vestibule of sufficient size to allow the inner door leaf to swing outward without interfering with the operation of the door leaf at the outer end of the vestibule. See Exhibit 7.41.

#### 7.2.1.4.5 Door Leaf Operating Forces.

**7.2.1.4.5.1** The forces required to fully open any door leaf manually in a means of egress shall not exceed 15 lbf (67 N) to release the latch, 30 lbf (133 N) to set the leaf in motion, and 15 lbf (67 N) to open the leaf to the minimum required width, unless otherwise specified as follows:

- (1) The opening forces for interior side-hinged or pivoted-swinging door leaves without closers shall not exceed 5 lbf (22 N).

**Exhibit 7.41**

*Arrangement of vestibule leading to screen door assembly complying with 7.2.1.4.4.*

- (2) The opening forces for existing door leaves in existing buildings shall not exceed 50 lbf (222 N) applied to the latch stile.
- (3) The opening forces for horizontal-sliding door leaves in detention and correctional occupancies shall be as provided in Chapters 22 and 23.
- (4) The opening forces for power-operated door leaves shall be as provided in 7.2.1.9.

**7.2.1.4.5.2** The forces specified in 7.2.1.4.5 shall be applied to the latch stile.

The Code recognizes that several movements are necessary to move a door leaf from its closed to its fully open position. Paragraph 7.2.1.4.5.1 identifies each of those movements and limits the force needed to accomplish each. The force required to unlatch the door assembly is limited to 15 lbf (67 N); the force necessary to start the door leaf in motion, or to overcome its inertia, is limited to not more than 30 lbf (133 N); and the force necessary to move the door leaf to its required open position is limited to not more than 15 lbf (67 N).

Care must be taken to ensure that the 30 lbf (133 N) needed to overcome the inertia of a door leaf in a means of egress is not exceeded for door assemblies opening into pressurized stairs. The pressure necessary to protect the stair often might be such that 30 lbf (133 N) is insufficient to open the door leaf. The use of barometric relief dampers or other pressure-regulating methods might be required. See NFPA 92, *Standard for Smoke Control Systems*.<sup>6</sup>

A person with severe mobility impairment, such as someone who uses a wheelchair, might find it difficult or impossible to exert even the 15 lbf (67 N) specified by 7.2.1.4.5. Specification of a lower operating force for self-closing door assemblies might adversely affect the door assembly closer's ability to perform its intended function of returning an open door leaf to the fully closed and latched position. For interior side-hinged or

pivoted-swinging door assemblies without closers, no conflict exists between the needs of a closer and those of a person with physical disabilities. Therefore, 7.2.1.4.5.1(1) specifies that such door assemblies be operable when not more than 5 lbf (22 N) is applied at the latch stile.

Circumstances such as wet floors, smooth-soled shoes, and light body weight can render many people incapable of exerting 50 lbf (222 N) horizontally. Therefore, the maximum 50 lbf (222 N) operating requirement of earlier editions of the *Code* remains applicable only to existing door assemblies via the provisions of 7.2.1.4.5.1(2).

Paragraphs 7.2.1.4.5.1(3) and (4) address special situations where the operating force requirements of 7.2.1.4.5 cannot be applied. For horizontal-sliding door assemblies in detention and correctional occupancies, see 22.2.11.6 and 23.2.11.6. For requirements specific to power-operated door assemblies, see 7.2.1.9.

Paragraph 7.2.1.4.5.2 clarifies where the forces specified in 7.2.1.4.5.1 are to be applied, namely to the latch stile.

### 7.2.1.5 Locks, Latches, and Alarm Devices.

An increase in thefts, muggings, and similar crimes has led to the practice of providing extra security on door assemblies within the means of egress. Such a practice, particularly where door assemblies to exit stairs and exit discharges are involved, is an open invitation to tragedy in the event of fire or other emergency. The provisions of 7.2.1.5 are aimed at preventing locked door assemblies in means of egress or any other unnecessary interference with the orderly movement of people through door openings in the event of fire. The *Code* has attempted to accomplish this objective while maintaining features that are essential to security within the building.

The requirement that door assemblies be easily openable from the egress side is consistent with the concept that all components in the means of egress must be under the control of the occupants. This requirement prohibits the use of key locks or hard-to-use devices, such as door handles or latches covered with glass that has to be broken. Where panic hardware or fire exit hardware is used, no device that might interfere with its operation can be used; however, this does not prevent the use of alarm connections that indicate that the door assembly is in use.

Requirements for door assemblies leading to exits also apply to door assemblies that open to roofs, where, for example, exit stairs from a high-rise portion of the building discharge to the roof of the low-rise portion of the building, and to exit discharge door assemblies leading to the street or other public way.

**7.2.1.5.1** Door leaves shall be arranged to be opened readily from the egress side whenever the building is occupied.

**7.2.1.5.2\*** The requirement of 7.2.1.5.1 shall not apply to door leaves of listed fire door assemblies after exposure to elevated temperature in accordance with the listing, based on laboratory fire test procedures.

**A.7.2.1.5.2** Some fire door assemblies are listed for use with fire pins or fusible links that render the door leaf release inoperative upon exposure to elevated temperature during a fire. The door leaf release mechanism is made inoperative where conditions in the vicinity of the door opening become untenable for human occupancy, and such door opening no longer provides a viable egress path.

**7.2.1.5.3** Locks, if provided, shall not require the use of a key, a tool, or special knowledge or effort for operation from the egress side.

Paragraph 7.2.1.5.1 establishes the principle that, when a building is occupied, door assemblies must be able to be opened easily from the side from which egress is to be made.

The provision of 7.2.1.5.2 is explained in A.7.2.1.5.2.

Paragraph 7.2.1.5.3 prohibits the installation of locks that require the use of a key, a tool, or special knowledge or effort to open the door leaf from the egress side. Door assemblies are generally permitted to be locked from the nonegress side, so as to prevent unauthorized entry into a building. However, door assemblies from an exit stair enclosure to the building floors might have to provide for re-entry as detailed in 7.2.1.5.8.

See the commentary following 7.2.1.5.6(6), which explains the concept whereby a door assembly with a magnetic lock, with building access via a card reader, can be considered a normal door assembly in compliance with 7.2.1.5.1, 7.2.1.5.3, and 7.2.1.5.10 if the door leaf has a lever handle with an integral switch that releases the lock to allow free egress by building occupants.

**7.2.1.5.4** The requirements of 7.2.1.5.1 and 7.2.1.5.3 shall not apply where otherwise provided in Chapters 18 through 23.

Paragraph 7.2.1.5.4 cross-references the provisions applicable to health care occupancies and detention and correctional occupancies where door assemblies locked against egress by building occupants are permitted under specific conditions. For examples, see 18.1.1.1.7, 18.2.2.2.2, 18.2.2.2.4, 18.2.2.2.5, and similar provisions in Chapter 19. Also see 22.2.11.2 and 22.2.11.7 through 22.2.11.10 and similar provisions in Chapter 23.

### 7.2.1.5.5 Key-Operated Locks.

**7.2.1.5.5.1\*** Exterior door assemblies shall be permitted to have key-operated locks from the egress side, provided that all of the following criteria are met:

- (1) This alternative is permitted in Chapters 11 through 43 for the specific occupancy.
- (2) A readily visible, durable sign in letters not less than 1 in. (25 mm) high on a contrasting background that reads as follows is located on or adjacent to the door leaf: THIS DOOR TO REMAIN UNLOCKED WHEN THE BUILDING IS OCCUPIED.

- (3) The locking device is of a type that is readily distinguishable as locked.
- (4) A key is immediately available to any occupant inside the building when it is locked.

**A.7.2.1.5.5.1** Where the entrance consists of an exterior vestibule, the locking arrangement should be permitted on the egress side of either the interior or exterior door of the vestibule.

**7.2.1.5.5.2** The alternative provisions of [7.2.1.5.5.1](#) shall be permitted to be revoked by the authority having jurisdiction for cause.

The provisions of [7.2.1.5.5](#) address key-operated locks that must meet four conditions — one of which is that the appropriate occupancy chapter must specifically permit use of the exemption. Compliance with [7.2.1.5.5.1\(3\)](#), which requires that the locking device be of a type readily distinguishable as locked, is to be judged by the authority having jurisdiction. Locks specifically designed to meet this requirement often have an indicating window mechanism that displays the word “open” when the device is in the unlocked position and displays the word “locked” when the device is in the locked position.

In permitting up to 10 persons in a locked building (i.e., an unoccupied building, as addressed in [7.2.1.1.3](#)), the *Code* does not dismiss such occupants as unimportant. The *Code* recognizes that there are instances where a building must be occupied by security personnel or by janitorial crews when it is locked. Such persons are generally familiar with the premises, and the *Code* requires that they have keys available for egress when necessary. Also see the commentary following [7.2.1.1.3.2](#).

Some occupancies permit the use of the key-operated lock addressed by [7.2.1.5.5](#). Additional restrictions that might be imposed by the occupancy chapter are contained in the paragraphs referenced within parentheses in the list. For example, in new assembly occupancies, use of a key-operated lock is restricted to the main exit of a building with an occupant load of not more than 500 persons. In addition, the main exit of the assembly occupancy is required to consist of a single door leaf or single pair of door leaves, and any latch on the door leaf or leaves is required to be released by panic hardware.

The occupancies permitting the use of the key-operated lock addressed in [7.2.1.5.5](#) are as follows:

1. Assembly occupancies ([12.2.2.2.4](#), [13.2.2.2.4](#))
2. Mercantile occupancies ([36.2.2.2.2](#), [37.2.2.2.2](#))
3. Business occupancies ([38.2.2.2.2](#), [39.2.2.2.2](#))

**Exhibit 7.42** shows the sign required by [7.2.1.5.5.1\(2\)](#) in an assembly occupancy.

**7.2.1.5.6 Electrically Controlled Egress Door Assemblies.** Door assemblies in the means of egress shall be permitted to be electrically locked if equipped with approved, listed hardware, provided that all of the following conditions are met:

**Exhibit 7.42**

*Sign over door subject to locking in an assembly occupancy.*

- (1) The hardware for occupant release of the lock is affixed to the door leaf.
- (2) The hardware has an obvious method of operation that is readily operated in the direction of egress.
- (3) The hardware is capable of being operated with one hand in the direction of egress.
- (4) Operation of the hardware interrupts the power supply directly to the electric lock and unlocks the door assembly in the direction of egress.
- (5)\* Loss of power to the listed releasing hardware automatically unlocks the door assembly in the direction of egress.

**A.7.2.1.5.6(5)** Separate power supplies might be provided to the electronic lock and the releasing hardware. In this case, it is critical that the lock be arranged to release upon loss of power to the releasing hardware to ensure occupants can egress in the event of a power failure.

- (6) Hardware for new installations is listed in accordance with ANSI/UL 294, *Standard for Access Control System Units*.

The provisions of [7.2.1.5.6](#) address electrically controlled egress door assemblies as a normal door assembly and not as a special locking arrangement. Note that the provisions are positioned within [7.2.1.5](#), related to traditional locks and latches, and not within [7.2.1.6](#), which addresses specialized, nontraditional locking arrangements such as delayed-egress locking systems and access-controlled egress door assemblies.

The door assemblies addressed by [7.2.1.5.6](#) typically take the form of a door leaf that is held locked to its frame via an electromagnet. Authorities having jurisdiction, in enforcing the provisions of earlier editions of the *Code*, often required any door assembly with an electromagnetic lock to comply with one of the sets of provisions of [7.2.1.6](#) for special locking arrangements, regardless of how the lock was operated. The text of [7.2.1.5.6](#) has the effect of equating the electrically controlled lock to a traditional, mechanically latched or locked door.

The criteria detailed in 7.2.1.5.6(1) through (6) ensure that the electrically controlled egress door assembly meets the requirements of 7.2.1.5.1, 7.2.1.5.3, and 7.2.1.5.10, as well as additional safeguards imposed, because the lock is electrically controlled. See also the third sentence of A.7.2.1.5.10.

**7.2.1.5.7** Where permitted in Chapters 11 through 43, key operation shall be permitted, provided that the key cannot be removed when the door leaf is locked from the side from which egress is to be made.

Paragraph 7.2.1.5.7 permits the “captive key” hardware, as is permitted in lodging and rooming houses via the provisions of 26.2.3.6. The captive key lock has the potential for misuse and must be used carefully. The design of the lock is such that an occupant could unlock the door assembly from the inside, thus freeing the key; move through the door opening, taking the key to the outside; lock the door assembly from the outside; and leave the property — potentially leaving others locked in the building. Thus, this lock is permitted for limited use within the occupancy chapters.

**7.2.1.5.8\*** Every door assembly in a stair enclosure serving more than four stories, unless permitted by 7.2.1.5.8.2, shall meet one of the following conditions:

- (1) Re-entry from the stair enclosure to the interior of the building shall be provided.
- (2) An automatic release that is actuated with the initiation of the building fire alarm system shall be provided to unlock all stair enclosure door assemblies to allow re-entry.
- (3) Selected re-entry shall be provided in accordance with 7.2.1.5.8.1.

**A.7.2.1.5.8** It is intended that the re-entry provisions apply only to enclosed exit stairs, not to outside stairs. This arrangement makes it possible to leave the stairway at such floor if the fire renders the lower part of the stair unusable during egress or if the occupants seek refuge on another floor.

Every door assembly in a stair enclosure serving more than four stories in a new building or nonsprinklered high-rise existing building [see 7.2.1.5.8.2(1) and (2)] must be arranged to permit re-entry into the building. However, the Code recognizes the need for varying degrees of security and does specify some equivalent alternatives. Stairway door assemblies are permitted to be locked to the stairwell side if arranged to unlock automatically upon initiation of the fire alarm system. Selected re-entry is addressed in the commentary associated with 7.2.1.5.8.1.

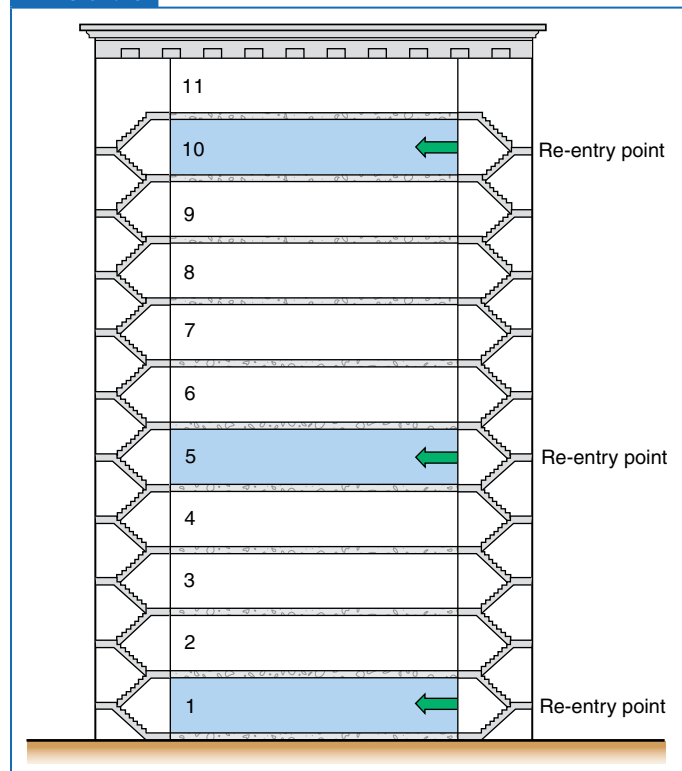

**7.2.1.5.8.1** Door assemblies on stair enclosures shall be permitted to be equipped with hardware that prevents re-entry into the interior of the building, provided that all of the following criteria are met:

- (1) There shall be not less than two levels where it is possible to leave the stair enclosure to access another exit.
- (2) There shall be not more than four stories intervening between stories where it is possible to leave the stair enclosure to access another exit.

- (3) Re-entry shall be possible on the top story or next-to-top story served by the stair enclosure, and such story shall allow access to another exit.
- (4) Door assemblies allowing re-entry shall be identified as such on the stair side of the door leaf.
- (5) Door assemblies not allowing re-entry shall be provided with a sign on the stair side indicating the location of the nearest door opening, in each direction of travel, that allows re-entry or exit.

Paragraph 7.2.1.5.8.1 permits some stair enclosure door assemblies, regardless of occupancy, to be locked to prevent re-entry on selected floors. In such instances, there must be at least two levels with unlocked door assemblies providing a way out of the stairway, one of which must be the top floor or the next to top floor; the other is usually the door assembly at the level of exit discharge. Because the Code prohibits more than four floors between floors that provide a way out of the stairway, stair enclosures serving more than six or seven stories must have more than two unlocked re-entry points. This arrangement provides flexibility in buildings that, perhaps for security reasons, need to prevent re-entry on certain floors, while at the same time ensuring that one can re-enter the building without having to travel up or down too many flights of stairs. See Exhibit 7.43. Any door assembly providing a way out of the stair enclosure must be identified as such on the stairwell side.

Exhibit 7.43

Stairway selected re-entry option.

**7.2.1.5.8.2** The requirements of **7.2.1.5.8**, except as provided in **7.2.1.5.8.3**, shall not apply to the following:

- (1) Existing installations in buildings that are not high-rise buildings as permitted in **Chapters 11** through **43**
- (2) Existing installations in high-rise buildings as permitted in **Chapters 11** through **43** where the occupancy is within a building protected throughout by an approved, supervised automatic sprinkler system in accordance with **Section 9.7**
- (3) Existing approved stairwell re-entry installations as permitted by **Chapters 11** through **43**
- (4) Stair enclosures serving a building permitted to have a single exit in accordance with **Chapters 11** through **43**
- (5) Stair enclosures in health care occupancies where otherwise provided in **Chapter 18**
- (6) Stair enclosures in detention and correctional occupancies where otherwise provided in **Chapter 22**

**7.2.1.5.8.3** When the provisions of **7.2.1.5.8.2** are used, signage on the stair door leaves shall be required as follows:

- (1) Door assemblies allowing re-entry shall be identified as such on the stair side of the door leaf.
- (2) Door assemblies not allowing re-entry shall be provided with a sign on the stair side indicating the location of the nearest door opening, in each direction of travel, that allows re-entry or exit.

In editions of the *Code* prior to 2009, the re-entry provisions were exempted for any existing stair installation where the applicable occupancy chapter specifically provided an exemption. The provisions of **7.2.1.5.8.2(1)** and **(2)** work together as follows:

1. Existing stair installations in a non-high-rise building are permitted to be exempted by the applicable occupancy chapter.
2. Existing stair installations in a high-rise building are permitted to be exempted by the applicable occupancy chapter only if the building is fully sprinklered.
3. Where the existing high-rise building is not sprinklered, re-entry in accordance with **7.2.1.5.8** is required.

Where an existing stairwell re-entry installation does not meet all the criteria of **7.2.1.5.8**, the provision of **7.2.1.5.8.2(3)** establishes that the existing installation can be continued in use if approved. The term *approved* means acceptable to the AHJ, and its definition appears in **3.2.1**.

**Paragraph 7.2.1.5.8.2(4)** recognizes that re-entry in buildings permitted to have a single exit is not necessary. In most single-exit buildings, the door assemblies from the stairway open directly into the occupant space. Most of the single-exit buildings recognized by the occupancy chapters are not more than four stories in height and are exempt from the stairwell re-entry provisions via the base paragraph of **7.2.1.5.8**.

**Paragraphs 7.2.1.5.8.2(5)** and **(6)** specify, for correlation with the occupancy chapters, that health care occupancies and detention and correctional occupancies are exempt from the

stair enclosure re-entry provisions. The exemption is based on the level of protection provided via a defend-in-place approach that minimizes the need for vertical evacuation by stairs or, where such movement is needed, relies heavily on staff with access to keys to direct the evacuation or relocation.

The provisions of **7.2.1.5.8.3** require signage in each exit stair enclosure serving more than four stories and not providing re-entry in accordance with the criteria of **7.2.1.5.8(1)**, **(2)**, or **(3)**. The signage must be installed on the stair side of each door leaf. The provisions of **7.2.1.5.8.3** are illustrated by the example that follows.

An existing business occupancy building is six stories in height above grade plane. Egress from all floors above floor 1 is provided by two remote exit stair enclosures that are accessed by a corridor on each floor. On floors 2 through 6, all door leaves from the corridor to the exit stair enclosures are locked from the stairwell side so as to prevent re-entry as permitted by **39.2.2.2.4(1)** and **7.2.1.5.8.2(1)**. On floor 1, the door from the corridor to each stair enclosure is left unlocked so as to permit re-entry onto the floor. In accordance with **7.2.1.5.8.3(2)**, the exit stair enclosure door leaves on floors 2 through 6 must be provided with signage, on the stair side, indicating that re-entry is provided at floor 1.

**7.2.1.5.9** If a stair enclosure allows access to the roof of the building, the door assembly to the roof either shall be kept locked or shall allow re-entry from the roof.

**Paragraph 7.2.1.5.9** was written to prevent building occupants from being trapped on a roof by a locked door assembly that does not permit re-entry into the building. If security concerns, for example, dictate that rooftop door assemblies are to be locked against entry from the outside, then the door assemblies also need to be locked from the inside to prevent unauthorized building occupants from going to the roof and becoming trapped. Note that there is no requirement that stair enclosure door assemblies provide rooftop access. Heroic helicopter rescues from rooftops of burning buildings are Hollywood movie illusions that seldom happen in real life.

**7.2.1.5.10\*** A latch or other fastening device on a door leaf shall be provided with a releasing device that has an obvious method of operation and that is readily operated under all lighting conditions.

**A.7.2.1.5.10** Examples of devices that might be arranged to release latches include knobs, levers, and bars. This requirement is permitted to be satisfied by the use of conventional types of hardware, whereby the door is released by turning a lever, knob, or handle or by pushing against a bar, but not by unfamiliar methods of operation, such as a blow to break glass. It is also within the intent of this requirement that switches integral to traditional doorknobs, lever handles, or bars, and that interrupt the power supply to an electromagnetic lock, be permitted, provided that they are affixed to the door leaf. The operating devices should be capable of being operated with

one hand and should not require tight grasping, tight pinching, or twisting of the wrist to operate.

**Paragraph 7.2.1.5.10** requires that, where a latch or other similar device is provided, the method of operation of its releasing device must be obvious, even in the dark. The intention of this requirement is that the method of release be one that is familiar to the average person. Generally, a two-step release, such as a knob and an independent slide bolt, is not permitted. In most occupancies, it is important that a single action unlatch the door assembly. See the commentary following **7.2.1.5.10.6** for an explanation of night latches permitted as a device in addition to the main latch/lock on residential occupancy dwelling unit door assemblies.

See the commentary following **7.2.1.5.6**, which explains the concept whereby a door assembly with a electrically controlled lock can be considered a normal door assembly in compliance with **7.2.1.5.1**, **7.2.1.5.3**, and **7.2.1.5.10** if the door assembly meets the criteria detailed in **7.2.1.5.6(1)** through (6), which include an arrangement where the locked door leaf is provided with a lever handle with an integral switch that releases the lock to allow free egress by building occupants.

**7.2.1.5.10.1** The releasing mechanism for any latch shall be located as follows:

- (1) Not less than 34 in. (865 mm) above the finished floor for other than existing installations
- (2) Not more than 48 in. (1220 mm) above the finished floor

**7.2.1.5.10.2** The releasing mechanism shall open the door leaf with not more than one releasing operation, unless otherwise specified in **7.2.1.5.10.3**, **7.2.1.5.10.4**, or **7.2.1.5.10.6**.

**7.2.1.5.10.3\*** Egress door assemblies from individual living units and guest rooms of residential occupancies shall be permitted to be provided with devices, including automatic latching devices, that require not more than one additional releasing operation, provided that such device is operable from the inside without the use of a key or tool and is mounted at a height not exceeding 48 in. (1220 mm) above the finished floor.

**A.7.2.1.5.10.3** Examples of devices that, when used with a latch, can be arranged to require not more than one additional releasing operation include night latches, dead bolts, and security chains.

**7.2.1.5.10.4** Existing security devices permitted by **7.2.1.5.10.3** shall be permitted to have two additional releasing operations.

**7.2.1.5.10.5** Existing security devices permitted by **7.2.1.5.10.3**, other than automatic latching devices, shall be located not more than 60 in. (1525 mm) above the finished floor.

**7.2.1.5.10.6** Two releasing operations shall be permitted for existing hardware on a door leaf serving an area having an occupant load not exceeding three, provided that releasing does not require simultaneous operations.

**Paragraph 7.2.1.5.10.1** specifies that new latch release mechanisms be located at least 34 in. (865 mm) above the floor and that both new and existing latch release mechanisms be not more than 48 in. (1220 mm) above the floor, so that the latch release is located in a position that is neither too low nor too high to be reached by persons in wheelchairs. The maximum mounting height for the latch release also helps to ensure that children can reach the latch.

**Paragraphs 7.2.1.5.10.3** and **7.2.1.5.10.4** provide an exemption to the requirement for a single releasing mechanism. The exemption recognizes the use, in residential living units and hotel guest rooms, of one additional device requiring release in new construction and two additional devices requiring release in existing installations. It permits an existing condition to continue where a hotel room door assembly, for example, has hardware arranged such that one operation releases the security chain or bar (i.e., night latch), another operation releases the dead bolt (usually via a thumb turn-type knob), and a third operation releases the door latch, usually by turning the doorknob or operating the door lever. However, in new installations, if a night latch or security device is installed, one operation would release the security device and a second operation, such as turning the doorknob or operating the door lever, would have to release both the dead bolt and normal door latch. Hardware that releases both the dead bolt and the normal door latch by turning the door lever is called a hotel latch set and is shown in **Exhibit 7.44**.

**Exhibit 7.44**

*Hotel latch set.*

Also, the *Code* prohibits supplemental automatic latching security devices from being located more than 48 in. (1220 mm) above the floor, even in existing buildings (see 7.2.1.5.10.3). This prohibition is intended to prevent children and wheelchair users from being trapped in a space when an automatic latching device that is located above reach range engages, locking the door assembly. Existing security devices that must be physically engaged are permitted in locations not more than 60 in. (1525 mm) above the floor (see 7.2.1.5.10.5), based on the assumption that the person engaging such a device is present to disengage it when needed.

Paragraph 7.2.1.5.10.6 offers a leniency to existing situations where two releasing operations are required to release the door latch. The allowance extends a practice formerly permitted only in residential occupancies, but it controls such situations by restricting the door to serving an area with an occupant load not exceeding three. It would permit a night chain to be dropped followed by the turning of a door knob. It does not permit simultaneous operations like sliding a bolt and then, while holding the bolt in its new position, turning a release lever.

**7.2.1.5.11** Where pairs of door leaves are required in a means of egress, one of the following criteria shall be met:

- (1) Each leaf of the pair shall be provided with a releasing device that does not depend on the release of one leaf before the other.
- (2) Approved automatic flush bolts shall be used and arranged such that both of the following criteria are met:
  - (a) The door leaf equipped with the automatic flush bolts shall have no doorknob or surface-mounted hardware.
  - (b) Unlatching of any leaf shall not require more than one operation.

The requirement of 7.2.1.5.11(1) for independent releasing hardware applies only to pairs of door leaves in a common door opening where both door leaves are required for means of egress. If a second leaf is provided for a reason other than required egress, that leaf can have a releasing mechanism that requires the egress leaf to be released first. However, in such a case, the leaf not used for egress must be arranged so as not to be mistaken for the egress door leaf.

Paragraph 7.2.1.5.11(2) permits a pair of door leaves — both a part of the required means of egress — to be placed within a common frame, whereby one leaf has no visible releasing hardware but has approved automatic flush bolts that release that leaf when the other leaf, which has visible hardware, is released. Therefore, the user is directed to the leaf with releasing hardware and disengages the latch on that leaf, and the other leaf automatically unlatches to allow its use if pushed in the direction of door leaf travel.

**7.2.1.5.12\*** Devices shall not be installed in connection with any door assembly on which panic hardware or fire exit hardware

is required where such devices prevent or are intended to prevent the free use of the leaf for purposes of egress, unless otherwise provided in 7.2.1.6.

**A.7.2.1.5.12** Examples of devices prohibited by this requirement include locks, padlocks, hasps, bars, chains, or combinations thereof.

It is not the intent of 7.2.1.5.12 to require panic hardware or fire exit hardware; that requirement is specified by the various occupancy chapters. Rather, 7.2.1.5.12 requires that, where panic hardware or fire exit hardware is installed, no device or arrangement is to interfere with its intended function. The intended function is the release of the latch when pressure — such as that exerted by persons pushing up against the door leaf — is applied to the bar or pad extending across the majority of the door leaf width [see 7.2.1.7.1(1)].

#### 7.2.1.6\* Special Locking Arrangements.

The special locking arrangements described in 7.2.1.6 include delayed-egress locking systems, access-controlled egress door assemblies, and elevator lobby exit access door assemblies locking. Each of these terms has a specific, but limited, meaning for purposes of applying the *Code*. For example, a building operator installs a magnetic lock on an outside door assembly and provides a card reader outside the building that releases the door assembly lock, so that only authorized persons are allowed entry to the building. Further, a lever handle is mounted on the inside surface of the door leaf and has an integral switch that releases the magnetic lock whenever a building occupant operates the lever. The building operator refers to this system as an access-controlled egress door assembly, but it is not the access-controlled egress door assembly addressed in 7.2.1.6.2, and it is not subject to those requirements. Rather, the door assembly locking system described is an electrically controlled egress door assembly subject to the provisions of 7.2.1.5.6. Such door assemblies in accordance with 7.2.1.5.6 comply with 7.2.1.5.1, 7.2.1.5.3, and 7.2.1.5.10 so as not to be special locking arrangements. The concept is further explained by A.7.2.1.6.2 and the third sentence of A.7.2.1.5.10.

NFPA staff answers *Code* questions from NFPA members and authorities having jurisdiction under a program referred to internally as Advisory Services or Technical Questions. A safety officer for a pharmaceutical manufacturer called in with a *Code* question. He explained that some of the pharmaceutical manufacturing facility exit door assemblies had magnetic locks released by card readers for both entry and exit. A consultant's report suggested to the safety officer that panic bar or push-pad releases be added to the door assemblies to directly release the lock for use in emergencies and that the facility continue to have employees use their pass cards for normal (i.e., nonemergency) entry/exit. Thus, the door assemblies would be treated as normal, manually released door assemblies not subject to any

special provisions, such as those for access-controlled egress door assemblies. The safety officer could not understand that he should not refer to the access-controlled egress door assembly provisions of the *Code* and that the door assemblies in question were not termed access-controlled by NFPA 701. He thought that the facility door assemblies were required to be tied into the fire alarm panel because of the access-controlled egress door assembly provisions. It took further explanation and reference to the text of A.7.2.1.5.10 and A.7.2.1.6.2 to assuage his concerns. The issue is further clarified by the provisions on electrically controlled egress door assemblies as detailed in 7.2.1.5.6.

**A.7.2.1.6** None of the special locking arrangements addressed in 7.2.1.6 are intended to allow *credentialed egress, request to exit*, or similar provisions, where an occupant cannot leave the building without swiping a card through a reader. Where such an arrangement is desired to keep track of occupants, the swiping of cards needs to be procedural but not necessary for releasing the door lock or latch. Free egress needs to be available at all times. Another option to free egress is the use of a delayed-egress locking system.

#### 7.2.1.6.1 Delayed-Egress Locking Systems.

**7.2.1.6.1.1** Approved, listed, delayed-egress locking systems shall be permitted to be installed on door assemblies serving low and ordinary hazard contents in buildings protected throughout by an approved, supervised automatic fire detection system in accordance with Section 9.6 or an approved, supervised automatic sprinkler system in accordance with Section 9.7, and where permitted in Chapters 11 through 43, provided that all of the following criteria are met:

- (1) The door leaves shall unlock in the direction of egress upon actuation of one of the following:
  - (a) Approved, supervised automatic sprinkler system in accordance with Section 9.7
  - (b) Not more than one heat detector of an approved, supervised automatic fire detection system in accordance with Section 9.6
  - (c) Not more than two smoke detectors of an approved, supervised automatic fire detection system in accordance with Section 9.6
- (2) The door leaves shall unlock in the direction of egress upon loss of power controlling the lock or locking mechanism.
- (3)\* An irreversible process shall release the lock in the direction of egress within 15 seconds, or 30 seconds where approved by the authority having jurisdiction, upon application of a force to the release device required in 7.2.1.5.10 under all of the following conditions:
  - (a) The force shall not be required to exceed 15 lbf (67 N).
  - (b) The force shall not be required to be continuously applied for more than 3 seconds.
  - (c) The initiation of the release process shall activate an audible signal in the vicinity of the door opening.

- (d) Once the lock has been released by the application of force to the releasing device, relocking shall be by manual means only.

**A.7.2.1.6.1.1(3)** It is not the intent to require a direct physical or electrical connection between the door release device and the lock. It is the intent to allow door movement initiated by operating the door release device required in 7.2.1.5.10 as one option to initiate the irreversible process.

Several factors need to be considered in approving an increase in delay time from 15 seconds to 30 seconds. Some of the factors include occupancy, occupant density, ceiling height, fire hazards present, fire protection features provided, and the location of the delayed-egress locks. An example of a location where the increase in delay time might not be approved is at an exit stair discharge door.

- (4)\* A readily visible, durable sign in letters not less than 1 in. (25 mm) high and not less than 1/8 in. (3.2 mm) in stroke width on a contrasting background shall be located on the door leaf adjacent to the release device in the direction of egress, and shall read as follows:
  - (a) PUSH UNTIL ALARM SOUNDS, DOOR CAN BE OPENED IN 15 SECONDS, for doors that swing in the direction of egress travel
  - (b) PULL UNTIL ALARM SOUNDS, DOOR CAN BE OPENED IN 15 SECONDS, for doors that swing against the direction of egress travel

**A.7.2.1.6.1.1(4)** In the event that the authority having jurisdiction has permitted increased operation time, the sign should reflect the appropriate time.

- (5) The egress side of doors equipped with delayed-egress locks shall be provided with emergency lighting in accordance with Section 7.9.

Delayed-egress locking systems prevent a door leaf from being opened for 15 seconds or 30 seconds under either nonemergency conditions or those encountered very early in a fire or similar emergency. Delayed-egress locking systems are to be used only where specifically permitted by the appropriate occupancy chapter. Their use is further limited to buildings protected throughout by either an approved, supervised automatic fire detection system or an approved, supervised automatic sprinkler system.

Paragraph 7.2.1.6.1.1(1) requires that the locking devices unlock upon activation of the corresponding detection or sprinkler system. The required detection system provides early warning; the alternately required sprinkler system provides early control of the fire — with each system performing to the degree necessary to make tolerable the delay experienced in waiting for the door leaf to be unlocked.

Paragraph 7.2.1.6.1.1(2) provides a fail-safe feature where, upon loss of the electrical power that controls the lock,

immediate unlocking from the egress side occurs. Note that, where the door leaf is unlocked, it is not required to be unlatched. Building occupants might need to operate the actuating bar or push pad to release the latch before opening the door, and the door might remain locked from the non-egress side. See the commentary three paragraphs below this paragraph.

**Paragraph 7.2.1.6.1.1(3)** requires that, once the release device is manually activated, the door leaf must unlock within 15 seconds, or 30 seconds with specific permission of the authority having jurisdiction. This action must be irreversible and cannot require the user to maintain pressure on the release device for more than 3 seconds. To provide occupants attempting egress with cues to indicate that the system is functioning, a signal is sounded in the vicinity of the door opening. Additionally, the signage required by **7.2.1.6.1.1(4)** provides useful, reassuring information.

After the door leaf is unlatched and physically opened (i.e., swung on its hinges away from the door frame), it is permitted to be relocked by manual means only. Relocking generally involves returning the door leaf to its closed and latched position and then resetting the system to engage the lock. Relatching is not prohibited, provided that the releasing mechanism (i.e., the push pad or actuating bar), when operated, unlatches the door leaf without any delay.

Note that the unlocking required by **7.2.1.6.1.1(1)**, **(2)**, and **(3)** need not automatically open the door leaf. Rather, the door leaf is permitted to remain latched. The unlocking allows the user to open the door leaf immediately by operating the releasing mechanism on the door leaf. Security is not sacrificed. Of course, any exterior exit door assembly is permitted to be locked against building entry at any time.

The positioning of the provision of **7.2.1.6.1.1(5)** reinforces an emergency lighting requirement of **7.9.1.1(4)**. It is helpful to the user to see the requirement repeated as part of the provisions for delayed-egress locking systems.

**Exhibit 7.45** shows delayed-egress locking hardware and the sign required by **7.2.1.6.1.1(4)** for doors that swing in the direction of egress travel.

Various occupancy chapters permit the use of delayed-egress locking systems in accordance with **7.2.1.6.1**. Additional restrictions that might be imposed by the occupancy chapter are contained in the paragraphs referenced within parentheses in the list. For example, lodging and rooming houses, hotels and dormitories, and apartment buildings permit delayed-egress locking systems if all the conditions of **7.2.1.6.1.1** are met and only one such lock is encountered along any natural path of egress travel.

The occupancies permitting delayed-egress locking systems are as follows:

1. Assembly occupancies (12.2.2.2.5, 13.2.2.2.5)
2. Educational occupancies (14.2.2.2.3.1, 15.2.2.2.3.1)
3. Day-care occupancies (16.2.2.2.3.1, 17.2.2.2.3.1)

**Exhibit 7.45**

*Delayed-egress locking hardware.*

4. Health care occupancies [18.2.2.2.4(2), 19.2.2.2.4(2)]
5. Ambulatory health care occupancies (20.2.2.2.6, 21.2.2.2.6)
6. Lodging or rooming houses (26.2.3.5.2)
7. Hotels and dormitories (28.2.2.2.2, 29.2.2.2.2)
8. Apartment buildings (30.2.2.2.2, 31.2.2.2.2)
9. Residential board and care occupancies [32.2.2.5.1, 32.3.2.2.2(4), 33.2.2.5.1, 33.3.2.2.2(4)]
10. Mercantile occupancies (36.2.2.2.5, 37.2.2.2.5)
11. Business occupancies (38.2.2.2.5, 39.2.2.2.5)
12. Industrial occupancies (40.2.2.2.2)
13. Storage occupancies (42.2.2.2.2, 42.8.2.2.2.2)

**7.2.1.6.1.2** The provisions of **7.2.1.6.2** for access-controlled egress door assemblies shall not apply to door assemblies with delayed-egress locking systems.

**Paragraph 7.2.1.6.1.2** serves mainly as a reminder that delayed-egress locking systems and access-controlled egress door assembly locking are two different features that are not to be intermixed. In the case of the delayed-egress locking systems, the releasing mechanism is mounted on the door leaf, and the system delays occupants from initially opening the door leaf. Access-controlled egress door assembly locking involves a door assembly that is not provided with an occupant-activated releasing mechanism on the door leaf and, therefore, relies on a motion detector to sense the approaching occupant, with the door leaf unlocking as the occupant reaches the door leaf.

**7.2.1.6.2\* Access-Controlled Egress Door Assemblies.** Where permitted in [Chapters 11](#) through [43](#), door assemblies in the means of egress shall be permitted to be equipped with electrical lock hardware that prevents egress, provided that all of the following criteria are met:

- (1) A sensor shall be provided on the egress side, arranged to unlock the door leaf in the direction of egress upon detection of an approaching occupant.
- (2) Door leaves shall automatically unlock in the direction of egress upon loss of power to the sensor or to the part of the access control system that locks the door leaves.
- (3) Door locks shall be arranged to unlock in the direction of egress from a manual release device complying with all of the following criteria:
  - (a) The manual release device shall be located on the egress side, 40 in. to 48 in. (1015 mm to 1220 mm) vertically above the floor, and within 60 in. (1525 mm) of the secured door openings.
  - (b) The manual release device shall be readily accessible and clearly identified by a sign that reads as follows: PUSH TO EXIT.
  - (c) When operated, the manual release device shall result in direct interruption of power to the lock — independent of the locking system electronics — and the lock shall remain unlocked for not less than 30 seconds.
- (4) Activation of the building fire-protective signaling system, if provided, shall automatically unlock the door leaves in the direction of egress, and the door leaves shall remain unlocked until the fire-protective signaling system has been manually reset.
- (5) The activation of manual fire alarm boxes that activate the building fire-protective signaling system specified in [7.2.1.6.2\(4\)](#) shall not be required to unlock the door leaves.
- (6) Activation of the building automatic sprinkler or fire detection system, if provided, shall automatically unlock the door leaves in the direction of egress, and the door leaves shall remain unlocked until the fire-protective signaling system has been manually reset.
- (7) The egress side of access-controlled egress doors, other than existing access-controlled egress doors, shall be provided with emergency lighting in accordance with [Section 7.9](#).

**A.7.2.1.6.2** It is not the intent to require doors that restrict access but that comply with [7.2.1.5.10](#) to comply with the access-controlled egress door provisions of [7.2.1.6.2](#). The term *access-controlled* was chosen when the requirements of [7.2.1.6.2](#) were first added to the *Code* to describe the function in which a door is electronically locked from the inside in a manner that restricts egress. It is not the *Code's* intent to prohibit methods of securing the door in a locked position from the outside with access control products, provided that the egress requirements of [7.2.1.6.2](#) are met.

The access-controlled egress door assemblies addressed by [7.2.1.6.2](#) are intended to be locked against access from the outside of the building and require a magnetic card or similar instrument for authorized entry. However, such door assemblies must be arranged for free egress use whenever the building is occupied. The *Code* addresses these door assemblies under the subject of special locking arrangements because such door assemblies generally do not have the leaf-mounted manual latch/lock release typically installed on egress door assemblies. The absence of the door leaf-mounted manual latch/lock release prevents a person on the outside from inserting a wire hanger or other tool between the gaps at the door leaf edges to reach the release. Use of access-controlled egress door assemblies requires specific occupancy chapter permission.

See the commentary following [7.2.1.6](#), which explains the concept whereby a door assembly with a magnetic lock, with building access via a card reader, can be considered a normal door assembly in accordance with [7.2.1.5.6](#) if the door leaf has a lever handle with an integral switch that releases the lock to allow free egress by building occupants.

Various occupancy chapters in the list that follows permit the use of access-controlled egress door assemblies in accordance with [7.2.1.6.2](#). Additional restrictions that might be imposed by the occupancy chapter are contained in the paragraphs referenced within parentheses in the list. For example, the provisions of [36.2.2.2.6](#) and [37.2.2.2.6](#), which apply to mercantile occupancies, permit access-controlled egress door assemblies if all conditions of [7.2.1.6.2](#) are met and the building is protected throughout by an approved, supervised fire detection system or an approved automatic sprinkler system. The provisions of [12.2.2.2.6](#) and [13.2.2.2.6](#), which apply to assembly occupancies, permit access-controlled egress door assemblies if all conditions of [7.2.1.6.2](#) are met and such doors are not locked from the egress side when the assembly occupancy is occupied — in other words, the access control locking system is permitted to be engaged only in the hours when the assembly occupancy is not occupied.

The occupancies permitting access-controlled egress door assemblies are as follows:

1. Assembly occupancies ([12.2.2.2.6](#), [13.2.2.2.6](#))
2. Educational occupancies ([14.2.2.2.3.2](#), [15.2.2.2.3.2](#))
3. Day-care occupancies ([16.2.2.2.3.2](#), [17.2.2.2.3.2](#))
4. Health care occupancies [[18.2.2.2.4\(3\)](#), [19.2.2.2.4\(3\)](#)]
5. Ambulatory health care occupancies ([20.2.2.2.7](#), [21.2.2.2.7](#))
6. Hotels and dormitories ([28.2.2.2.3](#), [29.2.2.2.3](#))
7. Apartment buildings ([30.2.2.2.3](#), [31.2.2.2.3](#))
8. Residential board and care occupancies [[32.2.2.5.2](#), [32.3.2.2.2\(5\)](#), [33.2.2.5.2](#), [33.3.2.2.2\(5\)](#)]
9. Mercantile occupancies ([36.2.2.2.6](#), [37.2.2.2.6](#))
10. Business occupancies ([38.2.2.2.6](#), [39.2.2.2.6](#))
11. Industrial occupancies ([40.2.2.2.3](#))
12. Storage occupancies ([42.2.2.2.3](#), [42.8.2.2.2.2](#))

Paragraph 7.2.1.6.2(1) provides for the door leaf to unlock when a sensor detects an occupant approaching the door opening. This method is the normal primary means of releasing the lock to allow occupants to leave the building. If the sensor and the release system fail, the requirements of 7.2.1.6.2(3) through (5) provide a backup system consisting of a manual lock release mounted at a usable height in the immediate vicinity of the door opening. The Code permits the manual release to be installed as much as 60 in. (1525 mm) from the secured door assembly, recognizing that the glass sidelights featured on many of these door assemblies are an impractical place to install a manual release device.

Additionally, 7.2.1.6.2(2) requires a fail-safe feature to unlock the door leaf, in the direction of egress travel, immediately upon loss of the electrical power that controls the lock.

Paragraphs 7.2.1.6.2(1) through (3) work together to help ensure that the door opening is usable at all times, before and during a fire emergency. Paragraphs 7.2.1.6.2(4) and (6) provide added assurance that the door opening is usable under fire emergency conditions. If the building has a fire alarm system, initiation of that system (by devices other than manual fire alarm boxes) must unlock the door leaf. If the building has either a fire detection system or a sprinkler system, activation of such system must unlock the door leaf.

Paragraph 7.2.1.6.2(5) clarifies that, if the building fire alarm system is initiated by a manual fire alarm box (formerly called a pull station), the door assembly is not required to unlock. This provision prevents an occupant who is intent on circumventing the security provided by such a door assembly from pulling the manual fire alarm box lever, which would initiate the alarm system and unlock the door assembly. Such an alarm initiation would readily defeat the purpose of the access-controlled egress door assembly locking provisions, which were developed to address security needs. The life safety features of the provisions of 7.2.1.6.2 are sufficient so as not to require an alarm initiation via a manual fire alarm box to unlock the door assembly.

The positioning of the provision of 7.2.1.6.2(7) reinforces the emergency lighting requirements of 7.9.1.1(6). It is helpful to the user to see the requirement repeated as part of the provisions for access-controlled egress door assemblies.

Exhibit 7.46 shows a glass door located across a hotel guest floor corridor. The door is held locked by an electromagnet and requires either a magnetic card to be read or a code to be punched into the key pad to unlock the door. The door is not required for egress for the occupants of the guest rooms in that portion of the corridor.

Exhibit 7.47 shows the same door depicted in Exhibit 7.46 but from the other side. The door serves as egress for the occupants of the guest rooms in that portion of the corridor. The door is equipped with access-controlled hardware. The motion sensor mounted at the ceiling unlocks the door upon occupant proximity. The “push to exit” button mounted on the wall serves as a backup should the motion sensor fail.

Exhibit 7.46

Non-egress side of access-controlled door assembly.

Exhibit 7.47

Egress side of access-controlled door assembly.

Provided that the applicable occupancy chapter permits access-controlled egress door assemblies, and such occupancy chapter does not add an additional requirement limiting location, the provisions of 7.2.1.6.2 are meant to permit access-controlled egress door assemblies to be installed and used anywhere in the egress path; and there can be multiple such devices encountered along any egress path. Unlike the delayed-egress lock, there is no waiting period before the door leaf is usable, other than having to push a release button in the uncommon situation where the electronics controlling the access-controlled device (such as the motion detector) fail.

**7.2.1.6.3 Elevator Lobby Exit Access Door Assemblies Locking.** Where permitted in Chapters 11 through 43, door assemblies separating the elevator lobby from the exit access required by 7.4.1.6.1 shall be permitted to be electrically locked, provided that all the following criteria are met:

- (1) The lock is listed in accordance with ANSI/UL 294, *Standard for Access Control System Units*.
- (2) The building is protected throughout by a fire alarm system in accordance with Section 9.6.
- (3) The building is protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7.
- (4) Waterflow in the sprinkler system required by 7.2.1.6.3(3) is arranged to initiate the building fire alarm system.
- (5) The elevator lobby is protected by an approved, supervised smoke detection system in accordance with Section 9.6.
- (6) Detection of smoke by the detection system required by 7.2.1.6.3(5) is arranged to initiate the building fire alarm system and notify building occupants.
- (7) Initiation of the building fire alarm system by other than manual fire alarm boxes unlocks the elevator lobby door assembly.
- (8) Loss of power to the elevator lobby electronic lock system unlocks the elevator lobby door assemblies.
- (9) Once unlocked, the elevator lobby door assemblies remain unlocked until the building fire alarm system has been manually reset.
- (10) Where the elevator lobby door assemblies remain latched after being unlocked, latch-releasing hardware in accordance with 7.2.1.5.10 is affixed to the door leaves.
- (11) A two-way communication system is provided for communication between the elevator lobby and a central control point that is constantly staffed.
- (12) The central control point staff required by 7.2.1.6.3(11) is capable, trained, and authorized to provide emergency assistance.
- (13) The provisions of 7.2.1.6.1 for delayed-egress locking systems are not applied to the elevator lobby door assemblies.
- (14)\* The provisions of 7.2.1.6.2 for access-controlled egress door assemblies are not applied to the elevator lobby door assemblies.

**A.7.2.1.6.3(14)** It is not the intent to prohibit elevator lobby doors from being equipped with card access systems for gaining access, for example, to tenant spaces. It is the access-controlled egress door system described in 7.2.1.6.2 that is prohibited from being installed on the same door as the lock addressed by 7.2.1.6.3.

The provisions of 7.2.1.6.3 provide the technical details supporting the exemption offered by 7.4.1.6.3 to the requirements of 7.4.1.6.1 and 7.4.1.6.2 for unencumbered access to at least one exit from each elevator landing and lobby.

The provisions of 7.2.1.6.3 for the locking of elevator lobby access door assemblies are permitted to be used only where another portion of the Code, typically an occupancy chapter, specifically permits their use. Many of the occupancy chapters were revised concurrently with the development of 7.2.1.6.3 to permit its use.

The occupancies permitting the locking of elevator lobby access door assemblies are as follows:

1. Assembly occupancies (12.2.2.2.7, 13.2.2.2.7)
2. Educational occupancies (14.2.2.2.3.3, 15.2.2.2.3.3)
3. Day-care occupancies (16.2.2.2.3.3, 17.2.2.2.3.3)
4. Health care occupancies [18.2.2.2.4(4), 19.2.2.2.4(4)]
5. Ambulatory health care occupancies (20.2.2.2.8, 21.2.2.2.8)
6. Hotels and dormitories (28.2.2.2.2.4, 29.2.2.2.2.4)
7. Apartment buildings (30.2.2.2.2.4, 31.2.2.2.2.4)
8. Mercantile occupancies (36.2.2.2.3, 37.2.2.2.3)
9. Business occupancies (38.2.2.2.3, 39.2.2.2.3)

Where the provisions of 7.2.1.6.3 are used, all the criteria detailed in 7.2.1.6.3(1) through (14) must be met. When the criteria of all 14 items are met, the locked door between the elevator lobby or landing and the exit should present a minimal, but tolerable, obstruction to speedy egress. The criteria blend a host of provisions for fire detection and alarm systems, sprinkler systems, occupant and staff two-way communication systems, and automatic lock release systems.

In earlier editions of the Code, there were 15 numbered criteria that had to be met in order to lock elevator lobby exit access door assemblies. The criterion prohibiting the elevator lobby electronic lock system from being supplied with emergency or standby electrical power was deleted, as such prohibition defeated necessary building security and could not be justified, provided that all the other criteria are met.

### 7.2.1.7 Panic Hardware and Fire Exit Hardware.

The difference between panic hardware and fire exit hardware is that fire exit hardware is tested and listed for use on fire-rated door assemblies; panic hardware is not (see 7.2.1.7.2). As the terms imply, panic hardware and fire exit hardware are designed for ease of use and functional reliability under conditions that range from an orderly evacuation to that of hurried egress that might accompany a fast-spreading fire. See 3.3.135.1 and 3.3.135.2 for definitions of *fire exit hardware* and *panic hardware*, respectively.

**Exhibit 7.48** shows fire exit hardware on a fire-rated door on an office building floor that has assembly occupancy meeting rooms. **Exhibit 7.49** shows the listing label on the fire exit hardware shown in **Exhibit 7.48**. **Exhibit 7.50** shows panic hardware on a gated (i.e., non-fire-rated) door opening in a public transportation assembly occupancy building.

The provisions of **7.2.1.7** do not require panic hardware; they do, however, set the requirements for such hardware if another portion of the *Code*, typically the applicable occupancy chapter, requires it.

**Exhibit 7.48**

Fire exit hardware on fire-rated door.

**Exhibit 7.49**

Fire exit hardware listing label.

**Exhibit 7.50**

Panic hardware on non-rated, gated door opening.

A few occupancy chapters require the use of panic hardware or fire exit hardware. Additional restrictions that might be imposed by the occupancy chapter are contained in the paragraphs referenced within parentheses in the list.

The occupancies that require the use of panic hardware or fire exit hardware are as follows:

1. Assembly occupancies (12.2.2.2.3, 13.2.2.2.3)
2. Educational occupancies (14.2.2.2.2, 15.2.2.2.2)
3. Day-care occupancies (16.2.2.2.2, 17.2.2.2.2)

Although not required for occupancies other than assembly, educational, and day-care, panic hardware or fire exit hardware is often used in other occupancies, either because an assembly occupancy is located within a multiple occupancy or because it is used as a means of complying with **7.2.1.5.10**. Additionally, **7.11.6**, which applies to high hazard contents areas, permits door assemblies from spaces with occupant loads of more than five persons to be provided with a latch or lock only if panic hardware or fire exit hardware is installed to release the latch or lock.

**7.2.1.7.1** Where a door assembly is required to be equipped with panic or fire exit hardware, such hardware shall meet all of the following criteria:

- (1) It shall consist of a cross bar or a push pad, the actuating portion of which extends across not less than one-half of the width of the door leaf.
- (2) It shall be mounted as follows:
  - (a) New installations shall be not less than 34 in. (865 mm), and not more than 48 in. (1220 mm), above the floor.
  - (b) Existing installations shall be not less than 30 in. (760 mm), and not more than 48 in. (1220 mm), above the floor.
- (3) It shall be constructed so that a horizontal force not to exceed 15 lbf (66 N) actuates the cross bar or push pad and latches.

Panic hardware and fire exit hardware are required to be instantly and easily released. New panic hardware and fire exit hardware installations are to be located 34 in. to 48 in. (865 mm to 1220 mm) above the floor [for existing installations — 30 in. to 48 in. (760 mm to 1220 mm)]. The actuating member or bar (see 3.3.4) is required to extend at least one-half the width of the door leaf, so as to create a target width sufficient to ensure that it will be engaged by the bodies of occupants pushing up against the door leaf. Such hardware, where mounted to a door leaf surface, might reduce the usable, clear width of a door opening. Provided that the hardware is installed at least 34 in. (865 mm) above the floor, the provisions of 7.2.1.2.1.1(5) permit a 4 in. (100 mm) encroachment on clear width without forcing a reduction in reported clear width. This is depicted in Figure A.7.2.1.2.1(b). Installed below 34 in. (865 mm), the panic hardware or fire exit hardware might create a reduction in clear width sufficient to obstruct wheelchair passage through the opening associated with a 34 in. (865 mm) width door leaf. Where panic hardware is installed below 34 in. (865 mm), such as at the 30 in. (760 mm) height permitted for existing hardware by 7.2.1.7.1(2)(b), the clear width measurement is reduced by the amount of the panic hardware encroachment.

The maximum force that the panic hardware or fire exit hardware actuating bar or member can require for operation is 15 lbf (66 N). Note that this is the force needed to release the latching device only. The force needed to open the door leaf itself is governed by 7.2.1.4.5.

**7.2.1.7.2\*** Only approved fire exit hardware shall be used on fire protection-rated door assemblies. New panic hardware and new fire exit hardware shall comply with ANSI/UL 305, *Standard for Safety Panic Hardware*, and ANSI/BHMA A156.3, *Exit Devices*.

It is not the intent of 7.2.1.7.2 to require the use of panic hardware or fire exit hardware. Only approved hardware is to be used, which means such hardware must be acceptable to the authority having jurisdiction, which generally relies on laboratory listing of the hardware. See the definition of *approved* in 3.2.1. Where such hardware is used on a fire-rated door assembly, it must be that special form of panic hardware termed *fire exit hardware* (see 3.3.135.1), which ensures that it has been tested for use on fire-rated door assemblies (with the AHJ generally making approval conditional on the device being listed; see 3.2.5). Additionally, new panic hardware and new fire exit hardware must comply with recognized industry standards.

**A.7.2.1.7.2** The presence of fire exit hardware on a door does not imply the door is required to be a fire protection-rated door.

**7.2.1.7.3** Required panic hardware and fire exit hardware, in other than detention and correctional occupancies as otherwise provided in Chapters 22 and 23, shall not be equipped with any locking device, set screw, or other arrangement that prevents the release of the latch when pressure is applied to the releasing device.

**7.2.1.7.4** Devices that hold the latch in the retracted position shall be prohibited on fire exit hardware, unless such devices are listed and approved for such a purpose.

It is the intent of the *Code* to permit the use of the delayed-egress lock described by 7.2.1.6.1 where panic hardware is required if the applicable occupancy chapter specifically permits use of the delayed-egress lock. In these cases, the actuating member or bar, which 7.2.1.7.1(1) requires to extend across at least half the door leaf width, serves as the device that initiates the irreversible process that results in the door leaf unlocking within the 15 seconds or 30 seconds specified.

Panic hardware, which is prohibited from being used on fire-rated door assemblies, often features the ability to “dog” the bar in the down position, so as to hold the door leaf latch in the retracted position. This latch-retracting feature is not available on fire exit hardware, because it would violate the listing of the rated fire door assembly. Rated door assemblies must self-latch upon being brought to the closed position by the required closing device. A latch helps to keep the door leaf closed under the pressures generated by a fire.

#### 7.2.1.8 Self-Closing Devices.

**7.2.1.8.1\*** A door leaf normally required to be kept closed shall not be secured in the open position at any time and shall be self-closing or automatic-closing in accordance with 7.2.1.8.2, unless otherwise permitted by 7.2.1.8.3.

**A.7.2.1.8.1** Examples of doors designed to normally be kept closed include those to a stair enclosure or horizontal exit.

**7.2.1.8.2** In any building of low or ordinary hazard contents, as defined in 6.2.2.2 and 6.2.2.3, or where approved by the authority having jurisdiction, door leaves shall be permitted to be automatic-closing, provided that all of the following criteria are met:

- (1) Upon release of the hold-open mechanism, the leaf becomes self-closing.
- (2) The release device is designed so that the leaf instantly releases manually and, upon release, becomes self-closing, or the leaf can be readily closed.
- (3) The automatic releasing mechanism or medium is activated by the operation of approved smoke detectors installed in accordance with the requirements for smoke detectors for door leaf release service in *NFPA 72, National Fire Alarm and Signaling Code*.
- (4) Upon loss of power to the hold-open device, the hold-open mechanism is released and the door leaf becomes self-closing.
- (5) The release by means of smoke detection of one door leaf in a stair enclosure results in closing all door leaves serving that stair.

**7.2.1.8.3** The elevator car doors, and the associated hoistway enclosure doors, at the floor level designated for recall in accordance with the requirements of 9.4.3 shall be permitted to remain open during Phase I Emergency Recall Operation.

Fire door assemblies in a means of egress route should be kept in the closed position, particularly those serving as entrances to a stair enclosure or positioned in a horizontal exit; however, it is in these two locations that door assemblies so often are held open by some type of door leaf stopping chock to aid in the free flow of normal traffic. This practice establishes conditions conducive to the rapid spread of fire, smoke, and heat to other sections of the building — the very situation that the stringent compartmentation requirements for the exit enclosure intend to prevent. **Exhibit 7.51** shows a door that is required to be self-closing and that has a self-closer whose purpose is defeated by a chair that holds the door in its open position in violation of the requirement of **7.2.1.8.1**.

Recognizing that tampering with the self-closing feature might occur — and in an effort to encourage the use of effective positive measures, rather than ineffective prohibitions that often go ignored — the *Code* presents criteria for holding door leaves in the open position. It permits door leaves to be held open in buildings that house low or ordinary hazard contents or where the authority having jurisdiction gives approval.

The provisions of **7.2.1.8.2** permit door leaves to be held open by an automatic releasing device. The triggering of the automatic release is done through the operation of smoke detectors installed in accordance with the requirements for smoke detectors for door release service as specified in *NFPA 72*<sup>®</sup>, *National Fire Alarm and Signaling Code*.<sup>7</sup> Fusible links are not an acceptable trigger in this system, because untenable smoke conditions could easily render an exit enclosure or adjoining fire compartment unusable long before the temperature in the vicinity of the door opening has risen enough to operate the fusible link.

Additionally, loss of power to the device providing the hold-open feature must cause immediate automatic release. A manual method of release is also required. The manual method

might involve tugging on the door leaf to cause its release. Therefore, magnetic devices with significant holding forces that are not easily overcome by a deliberate tug on the door leaf cannot be used. Once the hold-open device is released, the self-closing device installed on the door leaf swings the door leaf to its closed position. On a fire protection-rated door assembly, the required door latch then engages.

**Exhibit 7.52** depicts an automatic-closing door in the closed position and shows the door-mounted receptor plate and wall-mounted magnetic hold-open device near floor level. **Exhibit 7.53** shows the same door depicted in **Exhibit 7.52**, but in the open

**Exhibit 7.52***Automatic-closing door in closed position.***Exhibit 7.53***Automatic-closing door in open position.***Exhibit 7.51***Self-closing door held open by chair. (Photo courtesy of Jake Pauls)*

position, with the door receptor plate contacting the wall-mounted magnetic hold-open device.

The door leaves held open in accordance with the provisions of 7.2.1.8.2 can be arranged to close simultaneously throughout the building or only in the affected zones. Zoning is generally better, because it permits door assemblies in areas unaffected by the emergency to remain open to accommodate normal use. If protecting a room, that room might be considered a zone. If protecting a stair enclosure, the entire stair enclosure is considered a zone, and the signal to close one door leaf in the enclosing walls must close all door leaves in that stair enclosure.

With the exception of certain hazardous areas where flash fires or explosions could occur, the use of automatic closers in accordance with these provisions is permitted. Use of automatic-closing equipment should be encouraged to prevent door leaves from being secured open by other means. Wedges, for example, need to be removed manually before the self-closer installed on the door leaf can move the door leaf to its closed position.

Paragraph 7.2.1.8.3 helps to coordinate the door leaf closing requirements of 7.2.1.8 with the provisions of 9.4.3 for elevator recall. The Fire Fighters' Emergency Operations requirements for elevators, as specified by 9.4.3 and detailed in ASME A17.1/CSA B44, *Safety Code for Elevators and Escalators*,<sup>8</sup> mandates that an elevator — once recalled — is to remain at the designated recall floor with the elevator shaft and elevator car door leaves held in the open position. The open door leaves allow responding fire service personnel to ensure the elevator has been recalled. Paragraph 7.2.1.8.3 legitimizes a feature that would otherwise be prohibited by 7.2.1.8.1.

### 7.2.1.9\* Powered Door Leaf Operation.

**A.7.2.1.9** Special-purpose horizontally sliding accordion or folding door assemblies installed in accordance with 7.2.1.14 should not be considered powered doors subject to the provisions of 7.2.1.9.

Powered doors are divided into two categories — power assisted and power operated. Power-assisted doors that conform to ANSI/BHMA A156.19, *American National Standard for Power Assist and Low Energy Power Operated Doors*, use limited power to operate the door. They require fewer safeguards as compared to full power-operated doors. These door operators are for swinging doors only. Power-operated doors that conform to ANSI/BHMA A156.10, *American National Standard for Power Operated Pedestrian Doors*, require more power to operate the door and require additional safeguards to provide protection against personal injury. Power-operated doors can be swinging, sliding, or folding doors.

**7.2.1.9.1\* General.** Where means of egress door leaves are operated by power upon the approach of a person or are provided with power-assisted manual operation, the design shall be such that, in the event of power failure, the leaves open manually to allow egress travel or close when necessary to safeguard the means of egress.

**A.7.2.1.9.1** An example of the type of door addressed by 7.2.1.9.1 is one actuated by a motion-sensing device upon the approach of a person.

**7.2.1.9.1.1** The forces required to manually open the door leaves specified in 7.2.1.9.1 shall not exceed those required in 7.2.1.4.5, except that the force required to set the leaf in motion shall not exceed 50 lbf (222 N).

**7.2.1.9.1.2** The door assembly shall be designed and installed so that, when a force is applied to the door leaf on the side from which egress is made, it shall be capable of swinging from any position to provide full use of the required width of the opening in which it is installed. (See 7.2.1.4.)

**7.2.1.9.1.3** A readily visible, durable sign in letters not less than 1 in. (25 mm) high on a contrasting background that reads as follows shall be located on the egress side of each door opening:

IN EMERGENCY, PUSH TO OPEN

Power-operated door assemblies activated by an automatic mechanism are permitted, provided that their movement can be manually overpowered and the door leaf can be made to swing in the direction of egress travel while still providing the required egress capacity. The feature for manual operation must work at all times, even when other features of the door assembly's mechanism (such as the treadle, the electric eye, or the sliding rail) have failed. Such a door leaf must be arranged so it can be made to swing manually from any position, whether fully or partially closed. Care must be taken to ensure that the enclosing construction of any door leaf pocket does not defeat its ability to swing. Note that the breakaway feature cannot require a force in excess of 50 lbf (222 N).

The sign advising that the door leaf can be pushed open in an emergency provides the user with information that might not be intuitively obvious. Typically, the user sees the door operate under power, which involves the door leaf sliding to the side of the opening. The emergency manual mode of operation often relies on a breakaway feature that allows the door assembly to become side-hinged and swinging when pushed in the direction of egress travel.

**7.2.1.9.1.4** Sliding, power-operated door assemblies in an exit access serving an occupant load of fewer than 50 that manually open in the direction of door leaf travel, with forces not exceeding those required in 7.2.1.4.5, shall not be required to have the swing-out feature required by 7.2.1.9.1.2. The required sign shall be in letters not less than 1 in. (25 mm) high on a contrasting background and shall read as follows:

IN EMERGENCY, SLIDE TO OPEN

Recall that swinging door leaves, other than those in exit enclosures, serving an occupant load of fewer than 50 persons are permitted to swing against the direction of egress travel.

**Paragraph 7.2.1.9.1.4** considers a sliding door leaf that can be manually opened with forces not exceeding those required of swinging door leaves to be equivalent to a door leaf that swings against the direction of egress travel. **Paragraph 7.2.1.9.1.4** then exempts the breakaway feature described in the commentary that follows **7.2.1.9.1.3**.

Again, because the door leaf is power-operated during normal use, a sign must be provided advising the user that force can be used to slide the door leaf to its open position in an emergency mode — that is, on loss of power or equipment malfunction.

**7.2.1.9.1.5\*** In the emergency breakout mode, a door leaf located within a two-leaf opening shall be exempt from the minimum 32 in. (810 mm) single-leaf requirement of **7.2.1.2.3.2(1)**, provided that the clear width of the single leaf is not less than 30 in. (760 mm).

**A.7.2.1.9.1.5** Although a single power-operated door leaf located within a two-leaf opening might alone not provide more than 30 in. (760 mm) of clear width in the emergency breakout mode, where both leaves are broken out to become side hinged, the required egress width is permitted to be provided by the width of the entire opening.

**7.2.1.9.1.6** For a biparting sliding door assembly in the emergency breakout mode, a door leaf located within a multiple-leaf opening shall be exempt from the minimum 32 in. (810 mm) single-leaf requirement of **7.2.1.2.3.2(1)** if a clear opening of not less than 32 in. (810 mm) is provided by all leaves broken out.

**Paragraphs 7.2.1.9.1.5** and **7.2.1.9.1.6** recognize a design limitation of power-operated door assemblies currently manufactured and widely in use. Power-operated door assemblies that are capable of providing the minimum 32 in. (810 mm) clear width for a single leaf, as required by **7.2.1.2.3.2**, generally are not capable of providing the same minimum 32 in. (810 mm) clear width in the emergency breakout mode. As long as there are multiple leaves within a single opening and each is provided with the breakout feature, the 32 in. (810 mm) single-leaf requirement is relaxed, because the minimum required width can be provided by the entire opening with multiple door leaves broken out.

**7.2.1.9.1.7** Door assemblies complying with **7.2.1.14** shall be permitted to be used.

**7.2.1.9.1.8** The requirements of **7.2.1.9.1** through **7.2.1.9.1.7** shall not apply in detention and correctional occupancies where otherwise provided in **Chapters 22** and **23**.

**7.2.1.9.2 Self-Closing or Self-Latching Door Leaf Operation.** Where door leaves are required to be self-closing or self-latching and are operated by power upon the approach of a person, or are provided with power-assisted manual operation, they shall be permitted in the means of egress where they meet the following criteria:

- (1) The door leaves can be opened manually in accordance with **7.2.1.9.1** to allow egress travel in the event of power failure.
- (2) New door leaves remain in the closed position, unless actuated or opened manually.
- (3) When actuated, new door leaves remain open for not more than 30 seconds.
- (4) Door leaves held open for any period of time close — and the power-assist mechanism ceases to function — upon operation of approved smoke detectors installed in such a way as to detect smoke on either side of the door opening in accordance with the provisions of *NFPA 72, National Fire Alarm and Signaling Code*.
- (5) Door leaves required to be self-latching are either self-latching or become self-latching upon operation of approved smoke detectors per **7.2.1.9.2(4)**.
- (6) New power-assisted swinging door assemblies comply with BHMA/ANSI A156.19, *American National Standard for Power Assist and Low Energy Power Operated Doors*.

If a door assembly that is required to be self-closing or self-latching by a provision of the *Code* is a powered door assembly, the possibility of competing functions creating conflict exists. The intent of the self-closing or self-latching requirement is to keep the door leaf in its closed position, except when someone is moving through the door opening; the intent of a powered door assembly is either to cause the door leaf to open automatically upon approach of a person or to open via power assist when a limited force is applied against the door leaf. Under fire conditions, boxes falling from shelving, for example, might cause either the approach-actuated powered door assembly or force-actuated power-assist door assembly to open. The provisions of **7.2.1.9.2(4)** require that, upon detection of smoke, the door leaf closes and the power-assist mechanism ceases to function. This requirement emphasizes that the need for the door leaf to be in its closed position is paramount compared to the need to open the door leaf easily under fire conditions.

#### **7.2.1.10 Revolving Door Assemblies.**

Note that **7.2.1.10.1** applies to all revolving door assemblies, whether or not they are in the means of egress. **Paragraph 7.2.1.10.2** applies to revolving door assemblies within required means of egress. **Paragraphs 7.2.1.10.3** and **7.2.1.10.4** apply specifically to those revolving door assemblies that are not within the required means of egress.

Revolving doors with large opening size are common. The revolving door accommodates multiple persons per pocket and permits users to use the door while toting rolling suitcases, for example. **Exhibit 7.54** shows a large revolving door at the front entrance of a hotel.

**7.2.1.10.1** Revolving door assemblies, whether used or not used in the means of egress, shall comply with all of the following:

- (1) Revolving door wings shall be capable of being collapsed into a book-fold position, unless they are existing revolving doors approved by the authority having jurisdiction.

Exhibit 7.54

Revolving door at hotel entrance.

- (2) When revolving door wings are collapsed into the book-fold position, the parallel egress paths formed shall provide an aggregate width of 36 in. (915 mm), unless they are approved existing revolving door assemblies.
- (3) Revolving door assemblies shall not be used within 10 ft (3050 mm) of the foot or the top of stairs or escalators.
- (4) A dispersal area acceptable to the authority having jurisdiction shall be located between stairs or escalators and the revolving door assembly.
- (5) The revolutions per minute (rpm) of revolving door wings shall not exceed the values in [Table 7.2.1.10.1](#).
- (6) Each revolving door assembly shall have a conforming side-hinged swinging door assembly in the same wall as the revolving door within 10 ft (3050 mm) of the revolving door, unless one of the following conditions applies:
  - (a) Revolving door assemblies shall be permitted without adjacent swinging door assemblies, as required by [7.2.1.10.1\(6\)](#), in street floor elevator lobbies, provided that no stairways or door openings from other parts of the building discharge through the lobby and the lobby has no occupancy other than as a means of travel between the elevators and street.
  - (b) The requirement of [7.2.1.10.1\(6\)](#) shall not apply to existing revolving door assemblies where the number of revolving door assemblies does not exceed the number of swinging door assemblies within 20 ft (6100 mm) of the revolving door assembly.

The provisions of [7.2.1.10.1](#), which apply to revolving door assemblies, address collapsibility, width of egress path, location, speed of rotation, and supplementary swinging door assemblies. [Paragraphs 7.2.1.10.1\(1\)](#) and (2) require collapsibility to provide egress paths, albeit narrow paths, to each side of the

Table 7.2.1.10.1 Revolving Door Assembly Maximum Speed

Inside Diameter		Power-Driven Speed Control (rpm)	Manual Speed Control (rpm)
ft/in.	mm		
6 ft 6 in.	1980	11	12
7 ft	2135	10	11
7 ft 6 in.	2285	9	11
8 ft	2440	9	10
8 ft 6 in.	2590	8	9
9 ft	2745	8	9
9 ft 6 in.	2895	7	8
10 ft	3050	7	8

center column with attached book-fold position door leaves. [Paragraph 7.2.1.10.1\(3\)](#), which requires that revolving door assemblies not be used within 10 ft (3050 mm) of the foot or top of stairs or escalators, is meant to prevent the crushing accumulation of occupants if egress travel is slowed at the door opening. [Paragraph 7.2.1.10.1\(6\)](#) provides redundant egress via a nearby side-hinged swinging door leaf if the revolving door assembly prevents egress upon failure of its emergency features. [Paragraph 7.2.1.10.1\(6\)\(a\)](#) specifies a safe arrangement under which the additional swinging door assembly is not needed.

**7.2.1.10.2** Where permitted in [Chapters 11](#) through [43](#), revolving door assemblies shall be permitted as a component in a means of egress, provided that all of the following criteria are met:

- (1) Revolving door openings shall not be given credit for more than 50 percent of the required egress capacity.
- (2) Each revolving door opening shall not be credited with more than a 50-person capacity or, if of not less than a 9 ft (2745 mm) diameter, a revolving door assembly shall be permitted egress capacity based on the clear opening width provided when collapsed into a book-fold position.
- (3) Revolving door wings shall be capable of being collapsed into a book-fold position when a force not exceeding 130 lbf (580 N) is applied to the wings within 3 in. (75 mm) of the outer edge.

The occupancies permitting a revolving door assembly within the means of egress are as follows, and additional restrictions that might be imposed by the occupancy chapter are contained in the paragraphs referenced in parentheses in the list:

1. Assembly occupancies ([12.2.2.2.8](#), [13.2.2.2.8](#))
2. Hotels and dormitories ([28.2.2.2.3](#), [29.2.2.2.3](#))
3. Apartment buildings ([30.2.2.2.3](#), [31.2.2.2.3](#))
4. Existing residential board and care facilities [[33.3.2.2.2\(9\)](#)]
5. Mercantile occupancies ([36.2.2.2.9](#), [37.2.2.2.9](#))
6. Business occupancies ([38.2.2.2.9](#), [39.2.2.2.9](#))

Revolving door assemblies present the potential for problems when too many people try to use them in too short a period of time. The congestion created by such a situation is one reason

why their use is prohibited at the foot or top of stairs. This potential danger is also why they are not permitted to provide more than 50 percent of the required egress capacity. Where revolving door assemblies are used, they each receive credit for a maximum of 50 persons, regardless of the width of the revolving panel.

**7.2.1.10.3** Revolving door assemblies not used as a component of a means of egress shall have a collapsing force not exceeding 180 lbf (800 N) applied at a point 3 in. (75 mm) from the outer edge of the outer wing stile and 40 in. (1015 mm) above the floor.

The provision of **7.2.1.10.3** clarifies where the collapsing force measurement is to be made. The location specified is consistent with the requirements of BHMA/ANSI A156.27, *American National Standard for Power and Manual Operated Revolving Pedestrian Doors*.<sup>9</sup>

**7.2.1.10.4** The requirement of **7.2.1.10.3** shall not apply to revolving door assemblies, provided that the collapsing force is reduced to a force not to exceed 130 lbf (580 N) under all of the following conditions:

- (1) Power failure, or removal of power to the device holding the wings in position
- (2) Actuation of the automatic sprinkler system, where such a system is provided
- (3) Actuation of a smoke detection system that is installed to provide coverage in all areas within the building that are within 75 ft (23 m) of the revolving door assemblies
- (4) Actuation of a clearly identified manual control switch in an approved location that reduces the holding force to a force not to exceed 130 lbf (580 N)

Note that the provisions of **7.2.1.10.3** apply if the door assembly is not within the required means of egress. Note that **7.2.1.10.4** permits revolving door assemblies not used as a component of a means of egress to have a collapsing force in excess of the 180 lbf (800 N) specified in **7.2.1.10.3**, provided that the criteria of **7.2.1.10.4**(1) through (4) are met. Thus, the criteria contained in **7.2.1.10.4** need to be satisfied only if the collapsing force is in excess of 180 lbf (800 N) under normal operating conditions.

### 7.2.1.11 Turnstiles and Similar Devices.

The intent of **7.2.1.11** is to provide guidance on how best to place turnstiles in a building, to describe the circumstances under which they are permitted, and to reduce the chances of their improper use during an emergency.

**7.2.1.11.1** Turnstiles or similar devices that restrict travel to one direction or are used to collect fares or admission charges shall not be placed so as to obstruct any required means of egress, unless otherwise specified in **7.2.1.11.1.1**, **7.2.1.11.1.2**, and **7.2.1.11.1.3**.

**7.2.1.11.1.1** Approved turnstiles not exceeding 39 in. (990 mm) in height that turn freely in the direction of egress travel shall be

permitted where revolving door assemblies are permitted in **Chapters 11** through **43**.

**7.2.1.11.1.2** Where turnstiles are approved by the authority having jurisdiction and permitted in **Chapters 11** through **43**, each turnstile shall be credited for a capacity of 50 persons, provided that such turnstiles meet all of the following criteria:

- (1) They freewheel in the egress direction when primary power is lost, and freewheel in the direction of egress travel upon manual release by an employee assigned in the area.
- (2) They are not given credit for more than 50 percent of the required egress width.
- (3) They are not in excess of 39 in. (990 mm) in height and have a clear width of not less than 16½ in. (420 mm).

**7.2.1.11.1.3\*** Security access turnstiles that impede travel in the direction of egress utilizing a physical barrier shall be permitted to be considered as a component of the means of egress, where permitted in **Chapters 11** through **43**, provided that all the following criteria are met:

- (1) The building is protected throughout by an approved, supervised automatic sprinkler system in accordance with **Section 9.7**.
- (2) Each security access turnstile lane configuration has a minimum clear passage width of 22 in. (560 mm).
- (3) Any security access turnstile lane configuration providing a clear passage width of less than 32 in. (810 mm) shall be given an egress capacity of 50 persons.
- (4) Any security access turnstile lane configuration providing a clear passage width of 32 in. (810 mm) or more shall be given an egress capacity as calculated in accordance with **Section 7.3**.
- (5) Each secured physical barrier shall automatically retract or swing to an unobstructed open position in the direction of egress, under each of the following conditions:
  - (a) Upon loss of power to the turnstile or any part of the access control system that secures the physical barrier
  - (b) Upon actuation of a readily accessible and clearly identified manual release device that results in direct interruption of power to each secured physical barrier, remains in the open position for not less than 30 seconds, and is positioned at one of the following locations:
    - i. The manual release device is located on the egress side of each security access turnstile lane.
    - ii. The manual release device is located at an approved location where it can be actuated by an employee assigned to the area.
  - (c) Upon actuation of the building fire-protective signaling system, if provided, and for which the following apply:
    - i. The physical barrier remains in the open position until the fire-protective signaling system is manually reset.
    - ii. The actuation of manual fire alarm boxes that actuate the building fire-protective signaling system is

not required to meet the requirements specified in 7.2.1.11.1.3(5)(c)i

- (d) Upon actuation of the building automatic sprinkler or fire detection system, and for which the physical barrier remains in the open position until the fire-protective signaling system is manually reset

The provisions of 7.2.1.11.1.3 are new to the 2015 edition of the Code. Security access turnstiles limit entry to those with proper credentials, such as cards placed in proximity to an electronic reader. The security access turnstiles prevent unauthorized entry but are arranged to provide free egress under the conditions specified in 7.2.1.11.1.3(5). Exhibit 7.55 depicts security access turnstiles installed across ingress and egress paths. Note the small green lights on the stanchions for the two right lanes, indicating that the lanes will permit egress under normal day-to-day use as an occupant from within the secure area of the floor approaches. In this mode, the glass barrier is permitted to close off the opening as soon as any occupant has moved to the non-secure building area (i.e., lobby) outside the turnstile barricade. Similarly, the red light associated with the left lane indicates that the lane is in operation for ingress, as is further emphasized by the presence of the floor mat for cleaning shoe soles as occupants enter the building. In this mode, the glass barrier is permitted to close off the opening as soon as any occupant has moved to the secure building area inside the turnstile barricade. Under each of the conditions specified in 7.2.1.11.1.3(5), the glass barriers must automatically swing to the unobstructed open position. None of the conditions requiring actuation of the barrier

Exhibit 7.55

Security access turnstiles viewed from side providing egress. (Photo courtesy of U.S. General Services Administration)

permits the barrier to remain in the open position for less than 30 seconds; actuation by automatic sprinkler system water flow or fire detection requires the barrier to remain in the open position until the fire protective signaling system is reset.

**A.7.2.1.11.1.3** Security access turnstiles are designed to control security access into and out of buildings. Security access turnstiles might utilize physical barriers consisting of arms, wings, gates, or panels. The subject physical barriers come in various heights and function by retracting or opening in the direction of travel.

**7.2.1.11.2** Turnstiles exceeding 39 in. (990 mm) in height shall meet the requirements for revolving door assemblies in 7.2.1.10 or the requirements of 7.2.1.11.1.3 for security access turnstiles.

**7.2.1.11.3** Turnstiles located in, or furnishing access to, required exits shall provide not less than 16½ in. (420 mm) clear width at and below a height of 39 in. (990 mm) and at least 22 in. (560 mm) clear width at heights above 39 in. (990 mm).

Generally, turnstiles are installed to prevent or control entry. As such, they are not always suitable for installation in a means of egress. Turnstiles are permitted in means of egress locations where revolving door assemblies are permitted, unless an occupancy chapter specifically prohibits recognition of the turnstile; see the commentary following 7.2.1.10.2(3) for a list of occupancies that permit revolving door assemblies within the means of egress. Although assembly occupancies appear in the list as recognizing the use of revolving door assemblies, 12.2.2.2.9 and 13.2.2.2.9 prohibit turnstiles from serving within the means of egress. Exhibit 7.56 shows a turnstile used on a day-to-day basis for egressing a public transportation assembly occupancy building. The required egress opening is provided by the gated, swinging door with panic hardware latch release.

Exhibit 7.56

Assembly occupancy turnstile with required egress provided by gated, swinging door.

The reference in 7.2.1.11.1.1 to revolving door assemblies is not meant to imply that there is a relationship between their purpose and that of turnstiles. The revolving door assembly is not meant to restrict traffic in either direction, while the turnstile is often used to do just that, with the restriction or obstruction to traffic movement usually in the direction of building entry. Yet, if a turnstile does not restrict egress, it might be assumed to be the equivalent of a revolving door assembly. At heights not exceeding 39 in. (990 mm), a freewheeling turnstile is not required to provide the collapsibility features required of a revolving door assembly; turnstiles with heights exceeding 39 in. (990 mm) must be provided with all the features applicable to revolving door assemblies.

Some turnstiles do not turn in the direction of entry until coin-operated. Others require no coin for operation and are used simply to count numbers of people. Perhaps the most dangerous are those that do not bar entry but specifically bar egress. This situation might occur in large mercantile occupancies where turnstiles turn freely on entering but do not turn in the direction of egress, thereby causing patrons to reroute their egress through checkout stands. It is possible that the patrons of locations using one-way turnstiles are quite aware of this limitation and know the correct path to take for emergency egress; however, this knowledge cannot be relied on, especially if the turnstiles are placed near the exit door assemblies. In emergencies, occupants might head for what appears to be the shortest route to the outside, only to find it blocked by a turnstile preventing movement in that direction.

Some occupancy chapters, via their recognition of revolving doors (see 7.2.1.11.1.1), permit turnstiles to provide a portion of the required egress capacity, provided that they are in strict compliance with the dimensional criteria and performance requirements of 7.2.1.11.1.2. Turnstiles are not permitted to provide more than 50 percent of the required egress capacity, and no single turnstile can be given egress capacity for more than 50 persons.

**7.2.1.12 Door Openings in Folding Partitions.** Where permanently mounted folding or movable partitions divide a room into smaller spaces, a swinging door leaf or open doorway shall be provided as an exit access from each such space, unless otherwise specified in 7.2.1.12.1 and 7.2.1.12.2.

**7.2.1.12.1** A door leaf or opening in the folding partition shall not be required, provided that all of the following criteria are met:

- (1) The subdivided space is not used by more than 20 persons at any time.
- (2) The use of the space is under adult supervision.
- (3) The partitions are arranged so that they do not extend across any aisle or corridor used as an exit access to the required exits from the story.
- (4) The partitions conform to the interior finish and other requirements of this *Code*.

- (5) The partitions are of an approved type, have a simple method of release, and are capable of being opened quickly and easily by experienced persons in case of emergency.

**7.2.1.12.2** Where a subdivided space is provided with not less than two means of egress, the swinging door leaf in the folding partition specified in 7.2.1.12 shall not be required, and one such means of egress shall be permitted to be equipped with a horizontal-sliding door assembly complying with 7.2.1.14.

Exhibit 7.57 shows a door, required by 7.2.1.12, in a folding partition in a hotel multi-function assembly space.

Although 7.2.1.12.1(3) might appear to be so stringent as to make the exemption offered by 7.2.1.12.1 unworkable, it prohibits the extension of the partition across the exit access for the rest of the floor, not the extension of the partition across the exit access for the small space created by closing the partition.

Exhibit 7.57

Door in folding partition.

**7.2.1.13 Balanced Door Assemblies.** If panic hardware is installed on balanced door leaves, the panic hardware shall be of the push-pad type, and the pad shall not extend more than approximately one-half the width of the door leaf, measured from the latch stile. [See 7.2.1.7.1(1).]

Balanced door assemblies do not have side hinges; instead, they have a pivot point that is offset from the stile edge of the door leaf. This arrangement helps reduce the force needed to open the door leaf. With balanced door assemblies, where the hinge or pivot point is set in from the edge of the door leaf, care must be taken to position the panic hardware actuating bar on the latch

side of the pivot point; otherwise, pushing on the actuating bar might actually help to hold the door leaf closed. This arrangement might be effectively accomplished using push-pad panic hardware, which more readily instructs the user where to push.

Exhibit 7.58 depicts a balanced door assembly; Exhibit 7.59 illustrates the difference between panic hardware with an

Exhibit 7.58

Balanced door assembly.

Exhibit 7.59

Panic hardware with actuating bar (top) and panic hardware with push-pad actuating member (bottom).

actuating bar and panic hardware with a push pad serving as the actuating member.

**7.2.1.14 Special-Purpose Horizontally Sliding Accordion or Folding Door Assemblies.** Special-purpose horizontally sliding accordion or folding door assemblies shall be permitted in means of egress, provided that all of the following criteria are met:

- (1) The door leaf is readily operable from either side without special knowledge or effort.
- (2) The force that, when applied to the operating device in the direction of egress, is required to operate the door leaf is not more than 15 lbf (67 N).
- (3) The force required to operate the door leaf in the direction of travel is not more than 30 lbf (133 N) to set the leaf in motion and is not more than 15 lbf (67 N) to close the leaf or open it to the minimum required width.
- (4) The door leaf is operable using a force of not more than 50 lbf (222 N) when a force of 250 lbf (1100 N) is applied perpendicularly to the leaf adjacent to the operating device, unless the door opening is an existing special-purpose horizontally sliding accordion or folding exit access door assembly serving an area with an occupant load of fewer than 50.
- (5) The door assembly complies with the fire protection rating, if required, and, where rated, is self-closing or automatic-closing by means of smoke detection in accordance with 7.2.1.8 and is installed in accordance with NFPA 80, *Standard for Fire Doors and Other Opening Protectives*.

The special type of horizontal-sliding door assembly addressed by 7.2.1.14 — the special-purpose horizontal-sliding accordion or folding door assembly — is different from a traditional horizontal-sliding door assembly. When force is applied to the door actuator in the direction of egress travel, the door leaf must slide to the side to allow passage. This concept is illustrated in Exhibit 7.60.

The provisions of 7.2.1.14 do not require specific occupancy chapter permission for use of horizontal-sliding door assemblies.

Exhibit 7.60

Horizontal-sliding door assembly operation.

The requirements for the installation of horizontal-sliding door assemblies address the following:

1. Simple method of operation from either side without special knowledge or effort
2. Force necessary to operate the door assembly
3. Fire protection rating applicable to door assembly location and purpose
4. Automatic-closing means by smoke detection or means for self-closing

The force requirements of 7.2.1.14(3) and (4) help to ensure that the door assembly can be operated if the usual method of operation required by 7.2.1.14(2) fails.

It is important that sliding door assemblies, other than those addressed by 7.2.1.4.1(4)(c), (4)(d), or (5), be evaluated for compliance with all the requirements of 7.2.1.14. Traditional sliding door assemblies do not comply with these requirements; an example of a type of door assembly that does comply is shown in Exhibit 7.61.

Exhibit 7.61

Special-purpose horizontally-sliding accordion door assembly addressed by 7.2.1.14. (Photo courtesy of Won-Door Corp.)

### 7.2.1.15 Inspection of Door Openings.

**7.2.1.15.1\*** Where required by Chapters 11 through 43, the following door assemblies shall be inspected and tested not less than annually in accordance with 7.2.1.15.2 through 7.2.1.15.7:

- (1) Door leaves equipped with panic hardware or fire exit hardware in accordance with 7.2.1.7
- (2) Door assemblies in exit enclosures
- (3) Electrically controlled egress doors
- (4) Door assemblies with special locking arrangements subject to 7.2.1.6

**A.7.2.1.15.1** Door assemblies within the required means of egress (e.g., door assemblies that discharge from exit enclosures) require a higher level of care and maintenance throughout the

life of their installations to ensure they perform as intended by the Code. Annual inspection and functional testing of these door assemblies is necessary to verify that they are maintained in proper working condition. Panic hardware and fire exit hardware devices are specifically required to be used in assembly and educational occupancies. However, door leaves that are equipped with panic hardware or fire exit hardware, in areas not specifically required by the Code (e.g., stairwell entry doors and double-egress cross-corridor door assemblies not serving an assembly occupancy), should be subject to annual inspection and functional testing to ensure that the operating hardware functions correctly in accordance with 7.2.1.7, since the presence of panic hardware and fire exit hardware implies it is required by the Code.

Additionally, door assemblies that are electrically controlled egress doors in accordance with 7.2.1.5.5 and door assemblies that are equipped with special locking arrangements in accordance with 7.2.1.6 are outfitted with electrified hardware and access control devices that are susceptible to wear and abuse. Consequently, these door assemblies need to be inspected and tested on an annual basis, regardless of the occupant load being served.

In cases where the authority having jurisdiction determines there is a distinct hazard to building occupant safety, the inspection requirements of 7.2.1.15 should be applied to other exit access, exit, and exit discharge door assemblies.

The provisions of 7.2.1.15 address the inspection and testing of door openings with the features or uses specified in 7.2.1.15(1) through (4). The criteria for the inspection and testing of door openings apply only where specifically required by another portion of the Code, typically an occupancy chapter. Some of the door openings requiring inspection and testing will be fire-rated door assemblies and some will not. All door openings for fire-rated door assemblies are required to undergo similar inspection and testing per the requirements of 8.3.3.13.

The occupancies requiring inspection of door openings are as follows:

1. Assembly occupancies (12.7.1.3, 13.7.1.3)
2. Educational occupancies (14.7.3.3, 15.7.3.3)
3. Day-care occupancies (16.7.3.4, 17.7.3.4)
4. Residential board and care occupancies (32.7.7, 33.7.7)

**7.2.1.15.2\*** The inspection and testing interval for fire-rated and nonrated door assemblies shall be permitted to exceed 12 months under a written performance-based program.

**A.7.2.1.15.2** See NFPA 80, *Standard for Fire Doors and Other Opening Protectives*, Annex J, for information pertaining to performance-based inspection, testing, and maintenance of door assemblies.

**7.2.1.15.2.1** Goals established under a performance-based program shall provide assurance that the door assembly will perform its intended function.

**7.2.1.15.2.2** Technical justification for inspection, testing, and maintenance intervals shall be documented.

**7.2.1.15.2.3** The performance-based option shall include historical data.

The introductory requirements of 7.2.1.15.1 set the inspection and testing interval as once per year. Paragraph 7.2.1.15.2 provides an exemption so that the inspection interval can exceed 12 months. The text of A.7.2.1.15.2 advises that helpful information on a written performance-based program can be found in NFPA 80, *Standard for Fire Doors and Other Opening Protectives*.<sup>10</sup> NFPA 80 addresses the performance-based option for extending the inspection and testing interval. The concept of a performance-based inspection and testing frequency program is to establish the type and frequency of inspection needed to demonstrate that the door assemblies are operational. The goal is to balance the inspection frequency with proven reliability of the door assemblies; thus, the performance-based option is required to include historical data acceptable to the AHJ. The goal of a performance-based inspection program is also to adjust test and inspection frequencies commensurate with historical, documented equipment performance and desired reliability. Program attributes that should be considered in the adjustment of test and inspection frequencies include maintenance programs, usage frequencies, history of repairs, building condition, and consequence of failure of the door assemblies.

**7.2.1.15.3** A written record of the inspections and testing shall be signed and kept for inspection by the authority having jurisdiction.

The required written record of the inspection and testing must be signed, preferably by the individual who performed the inspection and testing.

**7.2.1.15.4** Functional testing of door assemblies shall be performed by individuals who can demonstrate knowledge and understanding of the operating components of the type of door being subjected to testing.

The functional testing of door assemblies is not required to be performed by a licensed or certified individual. Rather, the person performing the functional testing must be able to demonstrate knowledge and understanding of the operating components of the type of door assemblies required to be inspected at the facility.

**7.2.1.15.5** Door assemblies shall be visually inspected from both sides of the opening to assess the overall condition of the assembly.

The overall condition of the door assembly can be visually evaluated only if inspected from both sides of the door opening. Some features are evident from only the pull side of the door opening, as the stops in the frame prevent viewing the feature; other features, like the door closer, are evident only from the push side of the door opening.

**7.2.1.15.6** As a minimum, the following items shall be verified:

- (1) Floor space on both sides of the openings is clear of obstructions, and door leaves open fully and close freely.
- (2) Forces required to set door leaves in motion and move to the fully open position do not exceed the requirements in 7.2.1.4.5.
- (3) Latching and locking devices comply with 7.2.1.5.
- (4) Releasing hardware devices are installed in accordance with 7.2.1.5.10.1.
- (5) Door leaves of paired openings are installed in accordance with 7.2.1.5.11.
- (6) Door closers are adjusted properly to control the closing speed of door leaves in accordance with accessibility requirements.
- (7) Projection of door leaves into the path of egress does not exceed the encroachment permitted by 7.2.1.4.3.
- (8) Powered door openings operate in accordance with 7.2.1.9.
- (9) Signage required by 7.2.1.4.1(3), 7.2.1.5.5, 7.2.1.6, and 7.2.1.9 is intact and legible.
- (10) Door openings with special locking arrangements function in accordance with 7.2.1.6.
- (11) Security devices that impede egress are not installed on openings, as required by 7.2.1.5.12.
- (12) Where required by 7.2.2.5.5.7, door hardware marking is present and intact.
- (13) Emergency lighting on access-controlled egress doors and doors equipped with delayed-egress locking systems is present and functioning in accordance with Section 7.9.

The criteria required to be verified in 7.2.1.15.7(1) through (13) were developed to evaluate post-installation operating performance where the installation was made to comply with door assembly criteria of 7.2.1. Fire-rated door assemblies must also meet additional criteria as detailed in Section 5.2 of NFPA 80, *Standard for Fire Doors and Other Opening Protectives*, as required by 8.3.3.13.

**7.2.1.15.7\*** Door openings not in proper operating condition shall be repaired or replaced without delay.

**A.7.2.1.15.7** Performing corrective action work on door assemblies frequently requires ordering replacement components that might take time to produce, ship, and install. Consideration of the time it takes to procure and install components should be included in the timeline for restoring the door assemblies to normal working condition.

The purpose of the inspection and testing program is to identify problems with door assemblies. Paragraph 7.2.1.15.7 completes the process by requiring that problems be corrected without delay. The correction of the problem is part of the overall inspection and testing program and needs to be documented in the written record required by 7.2.1.15.3.

## 7.2.2 Stairs.

Stairs, whether interior or exterior to a building, serve multiple functions, including allowing normal occupant movement among the floors of a building, providing emergency egress in case of fire, and facilitating rescue and fire control operations conducted by fire fighters.

Stairs are used within any of the three components of a means of egress system; that is, the exit access, the exit, and the exit discharge. [Exhibit 7.62](#) shows an unenclosed inside stair used as exit access in the assembly meeting space of a hotel. [Exhibit 7.63](#) shows a stair and its enclosure, which together serve as an exit from the guest room floors of a hotel. [Exhibit 7.64](#)

**Exhibit 7.62**

*Unenclosed inside stair used as exit access.*

**Exhibit 7.63**

*Inside stair and its enclosure, which together serve as an exit. (Photo courtesy of Jake Pauls)*

**Exhibit 7.64**

*Outside stair used as exit discharge.*

shows an outside stair used as exit discharge from an amusement park building. All three stairs depicted are within the means of egress and are subject to the provisions of [7.2.2](#).

The *Code* focuses much attention on stairs to help ensure their effective use during emergency egress. These requirements for the use of emergency egress help to ensure that stairs are also safe to use on a regular basis. As one of the most commonly used building elements on a day-to-day, nonemergency basis, stairs are one of the most common scenes of missteps, trips, and falls. The progression of events encountered in a stair fall that begins with a stair user misstepping is simulated by the depictions in [Exhibit 7.65](#), [Exhibit 7.66](#) and [Exhibit 7.67](#).

Earlier editions of the *Code* addressed monumental stairs, but only to require that such stairs follow all the provisions applicable to standard stairs. The *Code* does not define the term *monumental stair*. A monumental stair is simply a regular stair that has been embellished for visual effect. The paragraph on monumental stairs was deleted because it added nothing to the *Code*, in that monumental stairs were required to meet all the usual stair criteria. A monumental stair is not a subset of stairs that have special features — it is a regular stair that might have extra width or substantial architectural detail. Contrast this description with a spiral stair (as addressed in [7.2.2.2.3](#)), which cannot meet the usual stair criteria and, therefore, must meet its own set of requirements if it is to be recognized within the means of egress.

### 7.2.2.1 General.

**7.2.2.1.1** Stairs used as a component in the means of egress shall conform to the general requirements of [Section 7.1](#) and to the special requirements of [7.2.2](#), unless otherwise specified in [7.2.2.1.2](#).

Exhibit 7.65

Progression of a stair fall — Part 1 of 3. (Photo courtesy of Jake Pauls)

Exhibit 7.66

Progression of a stair fall — Part 2 of 3. (Photo courtesy of Jake Pauls)

**7.2.2.1.2** The requirement of 7.2.2.1.1 shall not apply to the following:

- (1) Aisle stairs in assembly occupancies, as provided in Chapters 12 and 13
- (2) Approved existing noncomplying stairs

Assembly occupancy aisle stairs (i.e., stepped aisles) are detailed in 12.2.5.6 and 13.2.5.6.

Although stairs can serve within any of the three components of the means of egress, they are most often located within an exit. To be considered an exit, interior stairs must be separated from the other spaces on the floor in accordance with 7.1.3.2. Unenclosed interior stairs might serve as exit access but are not exits. Where an interior stair connects two or more stories, it creates a vertical opening and must meet the requirements applicable to such, regardless of whether it is an exit. See the vertical opening protection provisions of Section 8.6.

It is sometimes more difficult to determine whether outside stairs are part of the exit access, the exit, or the exit discharge. To be considered an exit, outside stairs need to be separated from the interior of the building by fire-rated construction in accordance with 7.2.2.6.3 or comply with an

Exhibit 7.67

Progression of a stair fall — Part 3 of 3. (Photo courtesy of Jake Pauls)

exemption of 7.2.2.6.3.1. Outside stairs adjacent to the building that are unprotected would normally be considered part of the exit access where serving occupants of upper stories, with the user reaching the exit and exit discharge simultaneously at the

base of the last stair flight. Where stairs occur in a sidewalk that connects an exit door assembly to a public way, the stairs are part of the exit discharge.

### 7.2.2.2 Dimensional Criteria.

#### 7.2.2.2.1 Standard Stairs.

7.2.2.2.1.1 Stairs shall meet the following criteria:

- (1) New stairs shall be in accordance with [Table 7.2.2.2.1.1\(a\)](#) and [7.2.2.2.1.2](#).
- (2)\* Existing stairs shall be permitted to remain in use, provided that they meet the requirements for existing stairs shown in [Table 7.2.2.2.1.1\(b\)](#).

**A.7.2.2.2.1.1(2)** It is the intent of [7.2.2.2.1.1\(2\)](#) to permit the use of [Table 7.2.2.2.1.1\(b\)](#) in existing buildings, even where there is a change in occupancy per [4.6.11](#). Safety improvements should be made that are reasonable and feasible at minimal cost. Improvements include removal, repair, or replacement of step coverings, as described in [A.7.2.2.3.5](#), particularly [Figure A.7.2.2.3.5\(e\)](#), and addition of functional handrails and guardrails in place of, or in conjunction with, other rails, as described in [7.2.2.4](#).

- (3) Approved existing stairs shall be permitted to be rebuilt in accordance with the following:
  - (a) Dimensional criteria of [Table 7.2.2.2.1.1\(b\)](#)
  - (b) Other stair requirements of [7.2.2](#)
- (4) The requirements for new and existing stairs shall not apply to stairs located in industrial equipment access areas where otherwise provided in [40.2.5.3](#).

**Table 7.2.2.2.1.1(a) New Stairs**

Feature	Dimensional Criteria	
	ft/in.	mm
Minimum width	See <a href="#">7.2.2.2.1.2</a> .	
Maximum height of risers	7 in.	180
Minimum height of risers	4 in.	100
Minimum tread depth	11 in.	280
Minimum headroom	6 ft 8 in.	2030
Maximum height between landings	12 ft	3660
Landing	See <a href="#">7.2.1.3</a> , <a href="#">7.2.1.4.3.1</a> , and <a href="#">7.2.2.3.2</a> .	

Editions of the *Code* prior to 1981 required that the height of every riser and the width of every tread be so proportioned that the sum of two risers and a tread, exclusive of the tread nosing or projection, was not less than 24 in. (610 mm) nor more than

**Table 7.2.2.2.1.1(b) Existing Stairs**

Feature	Dimensional Criteria	
	ft/in.	mm
Minimum width clear of all obstructions, except projections not more than 4½ in. (114 mm) at or below handrail height on each side	36 in.	915
Maximum height of risers	8 in.	205
Minimum tread depth	9 in.	230
Minimum headroom	6 ft 8 in.	2030
Maximum height between landings	12 ft	3660
Landing	See <a href="#">7.2.1.3</a> and <a href="#">7.2.1.4.3.1</a> .	

25 in. (635 mm). This requirement was deleted because it was based on a 300-year-old French formula in which the inch was a slightly larger unit of measure than it is today. Moreover, people's feet and stride length — the basis for the formula — were somewhat smaller at that time. Also, the requirement was originally intended only for stairs of moderate steepness or pitch. These reasons, as well as information gathered by researchers on people movement, explain why the requirement was replaced by requirements that ensure good step geometry.

Because of the hardship and impracticality of rebuilding all existing stairs to the newer requirements, the *Code* permits existing stairs in existing buildings to comply with previous requirements. It also permits existing stairs to be rebuilt to the previous dimensional criteria, because a new stair might not fit in an existing stair enclosure. However, the rebuilt stair utilizing the older geometry must meet all other requirements of [7.2.2](#), including those relating to handrails. The text of [A.7.2.2.2.1.1\(2\)](#) provides guidance for judging the improvements that are reasonable.

The provisions applicable to the width of new stairs were changed for the 2006 edition of the *Code*. See the commentary that follows [7.2.2.2.1.2\(F\)](#).

Prior to the 2006 edition of the *Code*, existing stairs were classified as either Class A or Class B, depending on their tread depth and riser height. The Class A stair was a safer stair than Class B because it was limited to a maximum riser height of 7½ in. (190 mm) instead of the 8 in. (205 mm) permitted for Class B stairs; and it was required to have a minimum tread depth of 10 in. (255 mm) instead of the 9 in. (230 mm) permitted for Class B stairs. The last two occupancies that required existing stairs to be Class A dropped the requirement — it had applied to existing stairs used for student access in educational occupancies and existing stairs used for client access in day-care occupancies. Therefore, [Table 7.2.2.2.1.1\(b\)](#) was revised to reflect that the criteria associated with what had been Class B stairs have become the minimum recognized by all the occupancy

**Exhibit 7.68**

Stair user's toes extending over tread edge while heel scuffs riser.  
(Photo courtesy of Jake Pauls)

chapters. As such, there was no longer a need to differentiate existing stairs as being Class A or Class B — they currently are referred to simply as existing stairs.

See 7.1.7 for special requirements where stairs provide a total elevation change of not more than 21 in. (535 mm).

Table 7.2.2.2.1.1(a) specifies for new stair construction that tread depth must not be less than 11 in. (280 mm). Table 7.2.2.2.1.1(b) permits an existing tread depth of 9 in. (230 mm) to remain in use. Exhibit 7.68 shows a stair with a 9 in. (230 mm) tread depth where the male stair user's toes extend over the tread edge; the ball of his foot contacts the tread, but only at the expense of his heel contacting and scuffing the riser. The 11 in. (280 mm) tread depth required for new stairs provides more room for safe foot placement on the stair tread, decreasing the potential for misstepping.

#### 7.2.2.2.1.2\* Minimum New Stair Width. (See also 7.3.3.)

**A.7.2.2.2.1.2** In some cases, the egress capacity provisions of 7.3.3 will require a stair to have a greater width than the minimum specified in 7.2.2.2.1.2.

(A) Where the total occupant load of all stories served by the stair is fewer than 50, the minimum width clear of all obstructions, except projections not more than 4½ in. (114 mm) at or below handrail height on each side, shall be 36 in. (915 mm).

(B)\* Where stairs serve occupant loads exceeding that permitted by 7.2.2.2.1.2(A), the minimum width clear of all obstructions, except projections not more than 4½ in. (114 mm) at or below handrail height on each side, shall be in accordance with Table 7.2.2.2.1.2(B) and the requirements of 7.2.2.2.1.2(C), 7.2.2.2.1.2(D), 7.2.2.2.1.2(E), and 7.2.2.2.1.2(F).

**A.7.2.2.2.1.2(B)** The stair width requirement of 7.2.2.2.1.2(B) is based on accumulating the occupant load on each story the stair serves.

The accumulating of occupant load is done for the purposes of the requirements of 7.2.2.2.1.2 only. The egress capacity requirements of Section 7.3 are NOT cumulative on a story-by-story basis.

If additional exits provide egress capacity, the occupant load served by such additional exits, up to the limit permitted for the egress capacity of such additional exits, is not added to the total occupant load considered for the minimum stair width requirements of 7.2.2.2.1.2.

If horizontal exits are provided on any of the stories, the total occupant load of all compartments on the story with the horizontal exits is used in the calculation of the minimum stair width requirements of 7.2.2.2.1.2. The number of stairs permitted through application of horizontal exit requirements in 7.2.4 is not affected by the minimum stair width requirements of 7.2.2.2.1.2.

The examples that follow illustrate applications of the minimum stair width requirement.

A stair in a building two stories in height above grade plane that has 2000 persons on the second story, among 10 equally sized stairs that serve the second story, would be considered to have an occupant load of 200 persons for the purposes of applying Table 7.2.2.2.1.2(B). The minimum width of such a stair would be 44 in. (1120 mm).

For a building with a relatively large floor area, a typical 44 in. (1120 mm) stair would not be required to be increased in width until it serves a building approximately 14 stories in height above grade plane, calculated as follows:

$$\frac{2000 \text{ persons}}{147 \text{ persons per floor for a } 44 \text{ in. (1120 mm) width stair}} = 14 \text{ stories} \quad [\text{A.7.2.2.2.1.2(B)}]$$

For egress in the descending direction, only the stair width below the 14 stories with the total occupant load of 2000 persons per stair, or 4000 persons if served by two equally sized stairs, would need to be increased to 56 in. (1420 mm). If the building is 20 stories in height above grade plane, only the stairs on the lowest 7 stories would be required to have the 56 in. (1420 mm) width.

For a building 41 stories in height above grade plane with 200 persons on each story (or 8000 persons overall, not including the level of exit discharge), with two equally sized stairs, each stair would be considered to have an occupant load of 4000 persons for the purposes of applying Table 7.2.2.2.1.2(B). Only the portion of the stair serving 2000 persons would be required

**Table 7.2.2.2.1.2(B) New Stair Width**

Total Cumulative Occupant Load Assigned to the Stair	Width	
	in.	mm
<2000 persons	44	1120
≥2000 persons	56	1420

to have the wider width. If each story provides the same floor area for occupancy, the upper 20 stories would have 44 in. (1120 mm) stairs, and the lowest 20 stories would have the 56 in. (1420 mm) stairs, as a minimum.

(C) The total cumulative occupant load assigned to a particular stair shall be that stair's prorated share of the total occupant load, as stipulated in 7.2.2.2.1.2(D) and 7.2.2.2.1.2(E), calculated in proportion to the stair width.

(D) For downward egress travel, stair width shall be based on the total number of occupants from stories above the level where the width is measured.

(E) For upward egress travel, stair width shall be based on the total number of occupants from stories below the level where the width is measured.

(F) The clear width of door openings discharging from stairways required to be a minimum of 56 in. (1420 mm) wide in accordance with 7.2.2.2.1.2(B) shall be in accordance with 7.2.1.2.3.2(9).

The provisions of 7.2.2.2.1.2 apply to the minimum required width of new stairs as mandated by 7.2.2.2.1.1(1).

Paragraph 7.2.2.2.1.2(A) permits a new stair to have a 36 in. (915 mm) minimum width if the total occupant load of all stories served by the stair is fewer than 50. This is an exemption to the 44 in. (1120 mm) minimum width criterion of Table 7.2.2.2.1.2(B). It recognizes that the small total number of persons who will use the stair will do so in little time compared to larger groups, where persons avoid each other by staggering their entry onto the stair and by locating themselves so as to leave space between users.

Table 7.2.2.2.1.2(B) requires stairs serving large total cumulative occupant loads, such as those common to high-rise buildings, to be a minimum of 56 in. (1420 mm) in width. The increased width helps to facilitate counterflow on the stairs as might be experienced where building occupants have not completed their evacuation via stairs at the time emergency responders, such as fire fighters, arrive at the building. The minimum 56 in. (1420 mm) stair width lessens the challenges to stair use where occupant egress travel in one direction on the stairs (typically downward) occurs simultaneously with emergency responder ingress in the opposite direction (typically upward). The minimum 56 in. (1420 mm) stair width also makes for more comfortable and efficient use of the stair where two columns of occupants descend the stair flight simultaneously.

Paragraph 7.2.2.2.1.2(C) provides guidance on determining the total cumulative occupant load. Paragraph 7.2.2.2.1.2(D) provides that the width increase is not required to be applied to the upper stories where the total cumulative occupant load using that portion of the stairs is less than the 2000-person threshold. The examples that follow illustrate these provisions.

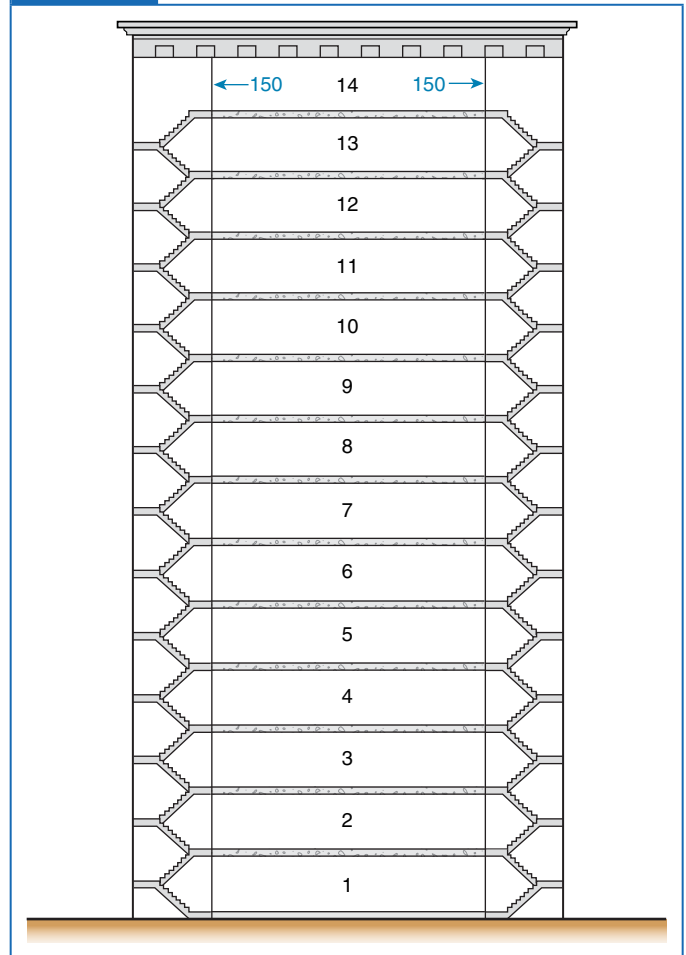

### Example 1: Determining Stair Width, 14-Story Building

Exhibit 7.69 depicts a 14-story building with a 300-person occupant load per floor. Floors 2 through 14 use the two exit stairs for egress. The occupants of the first floor use door assemblies directly to the outside (not shown) for egress. The means of egress system is designed for half of the occupant load of floors 2 through 14 to use the stair at the left of the exhibit, and for the other half to use the stair at the right of the exhibit. The sum of the 150 persons from each of floors 2 through 14 is considered the total cumulative occupant load assigned to each of the two stairs for purposes of applying 7.2.2.2.1.2(B). The total cumulative occupant load assigned to each of the two stairs is calculated as follows:

$$13 \text{ floors} \times 150 \text{ persons per floor per stair} = 1950 \text{ persons per stair}$$

Thus, the 2000-person threshold of Table 7.2.2.2.1.2(B) is not reached. No part of either stair is required to be increased to a minimum width of 56 in. (1420 mm). The stairs must be at least

Exhibit 7.69

Building where total cumulative occupant load does not require a 56 in. (1420 mm) minimum stair width.

44 in. (1120 mm) wide [per [Table 7.2.2.2.1.2\(B\)](#)], and wider if needed from a capacity consideration. In this case, the stairs must be 45 in. (1140 mm) wide, based on the following capacity calculation, which does not accumulate the occupant load from floor to floor in accordance with [7.3.1.4](#):

$$150 \text{ persons} \times 0.3 \text{ in. per person} = 45 \text{ in.}$$

$$(150 \text{ persons} \times 7.6 \text{ mm per person} = 1140 \text{ mm})$$

### Example 2: Determining Stair Width, 28-Story Building

[Exhibit 7.70](#) depicts a 28-story building (i.e., the 14-story building from [Exhibit 7.69](#) with 14 more stories added). See [Example 1](#) for a description of the means of egress and occupant load for each floor. The sum of the 150 persons per stair from each of floors 2 through 28 is considered the total cumulative occupant load assigned to each of the two stairs for purposes of applying [7.2.2.2.1.2\(B\)](#). The total cumulative occupant load assigned to each of the two stairs is calculated as follows:

$$27 \text{ floors} \times 150 \text{ persons} = 4050 \text{ persons per stair}$$

per floor per stair

Thus, the 2000-person threshold of [Table 7.2.2.2.1.2\(B\)](#) is exceeded. Some part of each of the two stairs is required to be increased to a minimum width of 56 in. (1420 mm).

[Paragraph 7.2.2.2.1.2\(D\)](#) exempts, from the increased minimum width, the upper portion of each of the two stairs for which the total cumulative occupant load assigned is fewer than 2000 persons. In this case, the transition point between the 45 in. (1140 mm) width required of the stair from a capacity consideration and the 56 in. (1420 mm) minimum width that facilitates counterflow occurs at the fifteenth story, calculated as follows:

$$\frac{2000 \text{ persons}}{150 \text{ persons per floor}} = 13.3 \text{ floors}$$

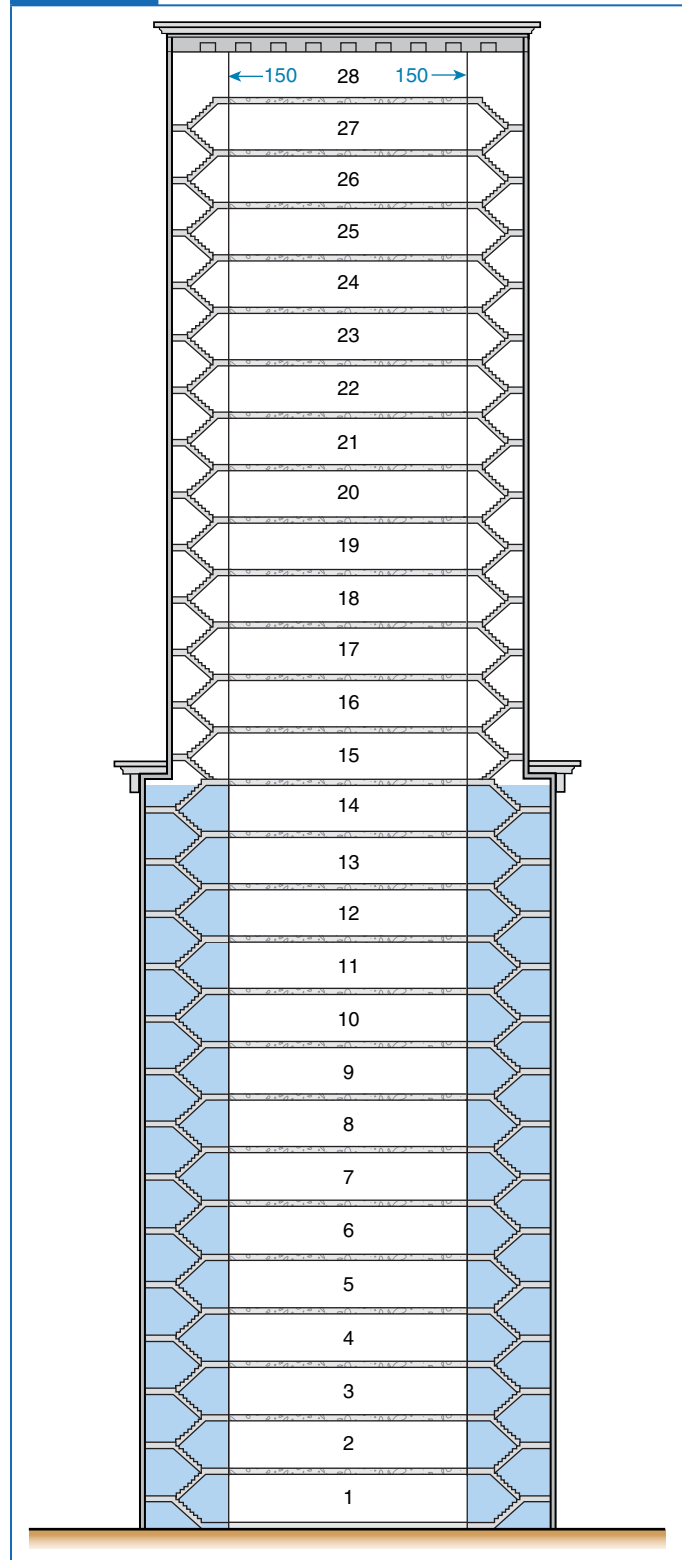

$$28 \text{ stories} - 13 \text{ upper stories} = \text{fifteenth story}$$

The stairs below the fifteenth story must provide the minimum 56 in. (1420 mm) width required by [Table 7.2.2.2.1.2\(B\)](#). This is shown in the shaded, lower portion of the stair enclosures in [Exhibit 7.70](#).

### Example 3: Determining Stair Width, Three-Story Mall Building

[Exhibit 7.71](#) depicts the third story of a new three-story mall building that utilizes horizontal exits for half of the required egress capacity, as permitted by [7.2.4.1.2](#) and [36.2.2.5](#). The occupant load of the third story is 6000 persons, of which the 20 exit stairs accommodate 3000 and the horizontal exits accommodate the other 3000. The second story is arranged and occupied the same as the third story. Occupants of the first floor are provided with adequate egress not involving use of the stairs.

**Exhibit 7.70**

Building where total cumulative occupant load requires a 56 in. (1420 mm) minimum stair width for the lower portion of the building.

Exhibit 7.71

Horizontal exits excluded in calculating total cumulative occupant load assigned to each stair.

The sixth paragraph of A.7.2.2.2.1.2(B) describes how to calculate the total cumulative occupant load assigned to each stair where horizontal exits exist. All occupants are to be assigned only to the stairs, without any consideration given to the horizontal exits, although the horizontal exits do count toward

satisfying the required egress capacity and the required number of exits. The reasoning behind excluding the horizontal exits from consideration is that persons using them have to wait on the safe side of the horizontal exit for their chance to use the exit stairs, which were not sized to handle the total occupant load of the floor. Therefore, for any of the stairs having a total cumulative occupant load of 2000 or more, it can be expected that the occupants will not have completed their evacuation stair travel when emergency responders arrive — and counterflow will occur on the stairs.

The total cumulative occupant load assigned to each of the 20 stairs is the sum of the occupant loads of floors 2 and 3 divided by the number of stairs, because, in this case, the stairs are all evenly sized. The calculation is as follows:

$$\frac{12,000 \text{ persons}}{20 \text{ stairs}} = 600 \text{ persons}$$

Thus, the 2000-person threshold of Table 7.2.2.2.1.2(B) is not reached. The stairs are not required to be increased to a minimum width of 56 in. (1420 mm). For the arrangement shown in Exhibit 7.71, the building would need to be at least eight stories high before any stair would be assigned a 2000-person or greater total cumulative occupant load so as to require a 56 in. (1420 mm) minimum stair width. A more realistic egress system design that would accommodate the 3000 persons per floor apportioned in Example 3 to the 20 stairs (i.e., the half of the floor's occupant load not apportioned to the horizontal exits) would typically involve fewer, but wider, stairs than the 45 in. (1140 mm) width used in this example, so as to make the 56 in. (1420 mm) criterion a nonissue.

Paragraph 7.2.2.2.1.2(F) serves as a reference to remind the user that related door width criteria are located in 7.2.1.2.3.2(9). The requirement of 7.2.1.2.3.2(9) ensures that, where a single door assembly serves as the discharge for stairs required to meet the 56 in. (1420 mm) minimum width criterion of Table 7.2.2.2.1.2(B), the door assembly is sized in proper proportion to the stair capacity to avoid creating a bottleneck at the door opening. See the commentary on 7.2.1.2.3.2(9).

#### 7.2.2.2.2 Curved Stairs.

**7.2.2.2.2.1** New curved stairs shall be permitted as a component in a means of egress, provided that the depth of tread is not less than 11 in. (280 mm) at a point 12 in. (305 mm) from the narrower end of the tread and the smallest radius is not less than twice the stair width.

**7.2.2.2.2.2** Existing curved stairs shall be permitted as a component in a means of egress, provided that the depth of tread is not less than 10 in. (255 mm) at a point 12 in. (305 mm) from the narrower end of the tread and the smallest radius is not less than twice the stair width.

Exhibit 7.72 shows a curved stair.

Exhibit 7.72

A curved stair. (Photo courtesy of Jake Pauls)

Paragraph 7.2.2.2.1 relates the degree of curvature to the width of the curved stair, as shown in Exhibit 7.73. Dimension *B* must be at least twice dimension *A*. Dimension *C*, the tread depth, is measured at the so-called inner walking line (where the stair users' feet land when walking on the inner part of the stair); tread depth must be at least 11 in. (280 mm). This relationship of smallest radius to stair width should be based on the actual width of the stair, rather than on the required width. Otherwise, unsafe conditions toward the outside of wide-curved stairs could be created.

The measurement method for curved stairs that is specified by the Code is based on how such stairs are used, with reference to a minimum 11 in. (280 mm) tread depth at the inner walking line. This concept has been used in the Code's requirement for

Exhibit 7.73

Dimensional requirements for curved stairs.

winders for some time (see 7.2.2.2.4). Because the minimum tread depth is stated as a dimension similar to that applicable to other stairs permitted in the required means of egress, it stands that curved stairs are an acceptable egress component for any occupancy.

### 7.2.2.2.3 Spiral Stairs.

**7.2.2.2.3.1** Where specifically permitted for individual occupancies by Chapters 11 through 43, spiral stairs shall be permitted as a component in a means of egress in accordance with 7.2.2.2.3.2 through 7.2.2.2.3.4.

**7.2.2.2.3.2** Spiral stairs shall be permitted, provided that all of the following criteria are met:

- (1) Riser heights shall not exceed 7 in. (180 mm).
- (2) The stairway shall have a tread depth of not less than 11 in. (280 mm) for a portion of the stairway width sufficient to provide egress capacity for the occupant load served in accordance with 7.3.3.1.
- (3) At the outer side of the stairway, an additional 10½ in. (265 mm) of width shall be provided clear to the other handrail, and this width shall not be included as part of the required egress capacity.
- (4) Handrails complying with 7.2.2.4 shall be provided on both sides of the spiral stairway.
- (5) The inner handrail shall be located within 24 in. (610 mm), measured horizontally, of the point where a tread depth of not less than 11 in. (280 mm) is provided.
- (6) The turn of the stairway shall be such that the outer handrail is at the right side of descending users.

**7.2.2.2.3.3** Where the occupant load served does not exceed three, spiral stairs shall be permitted, provided that all of the following criteria are met:

- (1) The clear width of the stairs shall be not less than 26 in. (660 mm).
- (2) The height of risers shall not exceed 9½ in. (240 mm).
- (3) The headroom shall be not less than 6 ft 6 in. (1980 mm).
- (4) Treads shall have a depth not less than 7½ in. (190 mm) at a point 12 in. (305 mm) from the narrower edge.
- (5) All treads shall be identical.
- (6) Handrails shall be provided on both sides of the stairway.

**7.2.2.2.3.4** Where the occupant load served does not exceed five, existing spiral stairs shall be permitted, provided that the requirements of 7.2.2.2.3.3(1) through (5) are met.

Exhibit 7.74 shows a large spiral stair. The stair does not have the inside handrail required by 7.2.2.2.3.2 for an existing spiral stair to be credited with egress capacity for more than five persons. See 7.2.2.2.3.4.

Spiral stairs can be used only where expressly permitted by the appropriate occupancy chapter. Some occupancy chapters establish additional limitations. For example, in assembly occupancies, spiral stairs are permitted only from lighting and access

Exhibit 7.74

A large spiral stair. (Photo courtesy of Jake Pauls)

catwalks, galleries, and gridirons. In apartment buildings, spiral stairs are permitted only within a dwelling unit, not within the common spaces and egress paths serving multiple dwelling units.

The occupancies that permit spiral stairs are as follows:

1. Assembly occupancies (12.2.2.3.2.2, 13.2.2.3.2.2)
2. Ambulatory health care occupancies (20.2.2.3.2, 21.2.2.3.2)
3. Detention and correctional occupancies (22.2.2.3.2, 23.2.2.3.2)
4. One- and two-family dwellings (24.2.5.5)
5. Apartment buildings (30.2.2.3.3, 31.2.2.3.3)
6. Mercantile occupancies (36.2.2.3.2, 37.2.2.3.2)
7. Business occupancies (38.2.2.3.2, 39.2.2.3.2)
8. Industrial occupancies (40.2.2.3.2)
9. Storage occupancies (42.2.2.3.2)

The requirement of 7.2.2.2.3.2 is significant in that it includes a spiral stair geometry that can be used without a prespecified maximum occupant limit. The number of occupants permitted to use a spiral stair depends on how much egress width is provided. The term *egress width* has a specific meaning in this instance. It excludes the narrow part of the tapered tread that has less than 11 in. (280 mm) of tread depth. It also excludes the outer 10½ in. (265 mm) of tread width. Note that handrails are required at both sides. Also, the turn of the stairway must be such that the outer handrail is available to descending users at their right side. These criteria are depicted in Exhibit 7.75. An additional criterion is that the riser height not exceed 7 in. (180 mm), as is required for traditional stairs in accordance with Table 7.2.2.2.1.1(a).

The requirement of 7.2.2.2.3.3 retains the dimensional criteria for spiral stairs from earlier editions of the Code but changes the maximum number of occupants served by the stair from five to three and requires that handrails be provided at both sides of the stair.

Exhibit 7.75

Spiral stair tread dimensional criteria reflecting the requirements of 7.2.2.2.3.2.

The requirement of 7.2.2.2.3.4 applies to existing spiral stairs. The traditional five-person limit and the requirement that a handrail be at the open side have been retained.

#### 7.2.2.2.4\* Winders.

**A.7.2.2.2.4** If properly designed and constructed, stairs with winders are not necessarily more dangerous than other stairs. Attention to the factors that follow helps to make winders generally more effective for egress and safety. Handrails should be continuous, without breaks at newel posts, from story to story. Handrails located at a greater than normal distance from the inner turn of winders can improve safety by constraining stair users to walk on the portion of the treads providing deeper treads, which should have not less than 11 in. (280 mm) of depth. Combinations of straight flights and winders are best arranged with winders located only below the straight flight. This arrangement is best because the winders provide larger tread dimensions over much of their width than do typical treads on straight flights. A descending person will, thus, be unlikely to experience a reduction of tread depth during descent, a condition of nonuniformity that is best avoided.

**7.2.2.2.4.1** Where specified in Chapters 11 through 43, winders shall be permitted in stairs, provided that they meet the requirements of 7.2.2.2.4.2 and 7.2.2.2.4.3.

**7.2.2.2.4.2** New winders shall have a tread depth of not less than 6 in. (150 mm) and a tread depth of not less than 11 in. (280 mm) at a point 12 in. (305 mm) from the narrowest edge.

**7.2.2.2.4.3** Existing winders shall be permitted to be continued in use, provided that they have a tread depth of not less than 6 in. (150 mm) and a tread depth of not less than 9 in. (230 mm) at a point 12 in. (305 mm) from the narrowest edge.

A winder is a tapered tread used to change the direction the stair runs. **Exhibit 7.76** depicts a winder. Because winders introduce a variation in the stair geometry and their effective tread depths are less than 11 in. (280 mm), they are suited to limited applications. At one time, the *Code* prohibited winders. **Chapter 7** currently sets applicable criteria for winders if the appropriate occupancy chapter specifically permits their use. Other than within dwelling units, the *Code* limits winders to existing installations. **Exhibit 7.77** illustrates the dimensional criteria required.

**Exhibit 7.76**

A winder stair. (Photo courtesy of Jake Pauls)

**Exhibit 7.77**

Acceptable winders.

Some occupancy chapters include additional limitations in addition to the criteria of **7.2.2.2.4**. For example, in new apartment buildings, winders are permitted to serve only within a living unit and not within the common spaces, such as corridors and lobbies. The occupancies that permit winders are as follows:

1. Existing ambulatory health care occupancies (**21.2.2.3.3**)
2. One- and two-family dwellings (**24.2.5.5**)
3. Lodging or rooming houses (**26.2.2.4**)
4. Apartment buildings (**30.2.2.3.4, 31.2.2.3.4**)
5. Residential board and care occupancies (**32.2.2.6.2, 33.2.2.6.2**)
6. Existing mercantile occupancies (**37.2.2.3.3**)
7. Existing business occupancies (**39.2.2.3.3**)
8. Existing industrial occupancies (**40.2.2.3.3**)
9. Existing storage occupancies (**42.2.2.3.3, 42.8.2.2.3.3**)

The provisions of **7.2.2.2.4.2** and **7.2.2.2.4.3** establish a minimum tread depth at a point 12 in. (305 mm) from the narrowest edge of the wedge-shaped tread in an effort to provide adequate depth for foot placement in the portion of the tread width most apt to be utilized by the winder stair user. In **Exhibit 7.78**, note that the wear pattern on the wedge-shaped treads identifies that users have consistently contacted the treads at approximately the distance from the narrowest edge prescribed by the tread depth requirement of **7.2.2.2.4.2** and **7.2.2.2.4.3**.

### 7.2.2.3 Stair Details.

#### 7.2.2.3.1 Construction.

**7.2.2.3.1.1** All stairs serving as required means of egress shall be of permanent fixed construction, unless they are stairs serving seating that is designed to be repositioned in accordance with **Chapters 12** and **13**.

**Exhibit 7.78**

Wear patterns on a winder stair. (Photo courtesy of Jake Pauls)

The requirement of 7.2.2.3.1.1 recognizes the functional requirement in theaters, for example, where seating sections are added, removed, or repositioned, depending on the specific theatrical production. It is impractical for stairs associated with such seating sections to be of fixed, permanent construction.

**7.2.2.3.1.2** Each stair, platform, and landing, not including handrails and existing stairs, in buildings required in this Code to be of Type I or Type II construction shall be of noncombustible material throughout.

The requirement of 7.2.2.3.1.2 covers the combustibility of materials used to construct new stairs. Stairs are permitted to be of combustible construction if the building is not required, by the \_\_\_1.6 subsection of the applicable occupancy chapter, to be of Type I or Type II construction as defined in NFPA 220, *Standard on Types of Building Construction*.<sup>11</sup> For example, the occupancy chapter might not have any requirements related to minimum building construction type, or the occupancy chapter might permit Type III, Type IV, or Type V construction. If the building is required to be of Type I or Type II construction, the materials used for new stair construction (i.e., stairs, platforms, and landings) must be noncombustible. For explanation of the term *noncombustible*, see 4.6.13.

### 7.2.2.3.2 Landings.

**7.2.2.3.2.1** Stairs shall have landings at door openings, except as permitted in 7.2.2.3.2.5.

**7.2.2.3.2.2** Stairs and intermediate landings shall continue with no decrease in width along the direction of egress travel.

**7.2.2.3.2.3** In new buildings, every landing shall have a dimension, measured in the direction of travel, that is not less than the width of the stair.

**7.2.2.3.2.4** Landings shall not be required to exceed 48 in. (1220 mm) in the direction of travel, provided that the stair has a straight run.

**7.2.2.3.2.5** In existing buildings, a door assembly at the top of a stair shall be permitted to open directly to the stair, provided that the door leaf does not swing over the stair and the door opening serves an area with an occupant load of fewer than 50 persons.

Stairs must have landings at door openings. It is unsafe to move through a door opening and immediately begin vertical travel on a stair. Paragraph 7.2.2.3.2.5 permits an existing situation in which a door assembly at the top of a stair opens directly at the stair without providing a level landing on the stair side of the door opening. In this case, however, the door leaf swings away from the stair, rather than swinging over the stair. Paragraph 7.2.1.3.6 recognizes the same concept of a step-down at exterior door assemblies. See Exhibit 7.32, associated with the commentary on 7.2.1.3.6, which depicts the exemption.

Intermediate stair landings of the minimum depth specified for new construction by 7.2.2.3.2.3 serve as effective breaks in

Exhibit 7.79

Required width of intermediate landings; required depth of new intermediate landings.

runs of stairs, which allow persons who slip or trip to halt their fall. Exhibit 7.79 illustrates the minimum landing width addressed by 7.2.2.3.2.2 and the minimum landing depth addressed by 7.2.2.3.2.3 and 7.2.2.3.2.4.

### 7.2.2.3.3 Tread and Landing Surfaces.

**7.2.2.3.3.1** Stair treads and landings shall be solid, without perforations, unless otherwise permitted in 7.2.2.3.5.

**7.2.2.3.3.2\*** Stair treads and landings shall be free of projections or lips that could trip stair users.

**A.7.2.2.3.3.2** The tripping hazard referred to in 7.2.2.3.3.2 occurs especially during descent, where the tread walking surface has projections such as strips of high-friction materials or lips from metal pan stairs that are not completely filled with concrete or other material. In addition, the installation of a retrofit, surface-mounted stair nosing or a strip of high-friction material onto an existing stair tread might produce a projection that creates a tripping hazard. For example, the slight elevation difference between the new stair tread nosing and the stair tread might create enough of an elevation change to trip the stair user. Tread nosings that project over adjacent treads can also be a tripping hazard. ICC/ANSI A117.1, *American National Standard for Accessible and Usable Buildings and Facilities*, illustrates projecting nosing configurations that minimize the hazard.

**7.2.2.3.3.3\*** Stair treads and landings within the same stairway shall have consistent surface traction.

**A.7.2.2.3.3.3** “Consistent surface traction” means that slip resistance is reasonably uniform and adequate to minimize risk of slipping across the treads where users’ feet contact the tread surface.

For the front-to-back direction, particular attention should be given to consistency of slip resistance in the front two-thirds of the tread, but preferably the entire tread surface. For descent, initial foot contact occurs at the nosing; for ascent, it occurs in the middle of the tread.

For the side-to-side direction, particular attention should be given to consistency of slip resistance within the clear width of the stair between handrails, especially on the portion contacted by users’ feet. For most users, this will extend to within about 6 in. (150 mm), measured horizontally, of the handrails; however, some vulnerable stair users might place the front portions of their feet below the handrails.

Consistency is important because misleading user expectation of underfoot conditions is a major factor in missteps and falls involving slipping.

Regarding the slip resistance of treads, it should be recognized that, when walking up or down stairs, a person’s foot exerts a smaller horizontal force against treads than is exerted when walking on level floors, including on landings. Therefore, materials used for floors that are acceptable as slip resistant (as described by ASTM F 1637, *Standard Practice for Safe Walking Surfaces* and standards specifically addressing tribology, including ANSI/ASSE A1264.2, *Standard for the Provision of Slip Resistance on Walking/Working Surfaces*) provide adequate slip resistance where used for stair treads. Such slip resistance includes the important leading edges of treads, the part of the tread that the foot first contacts during descent, which is the most critical direction of travel. If stair treads are wet, there is an increased danger of slipping, just as there is an increased danger of slipping on wet floors of similar materials. A small wash or drainage slope on exterior stair treads is, therefore, recommended to shed water. (See *Templer, J. A., The Staircase: Studies of Hazards, Falls, and Safer Design, Cambridge, MA: MIT Press, 1992.*)

The provision of **7.2.2.3.3.3** is new to the 2015 edition of the Code. Its robust annex text explains the concept of consistent surface traction.

**7.2.2.3.3.4** If not vertical, risers on other than existing stairs shall be permitted to slope under the tread at an angle not to exceed 30 degrees from vertical, provided that the projection of the nosing does not exceed 1½ in. (38 mm).

**7.2.2.3.3.5** The requirement of **7.2.2.3.3.1** shall not apply to noncombustible grated stair treads and landings in the following occupancies:

- (1) Assembly occupancies as otherwise provided in **Chapters 12 and 13**
- (2) Detention and correctional occupancies as otherwise provided in **Chapters 22 and 23**

- (3) Industrial occupancies as otherwise provided in **Chapter 40**
- (4) Storage occupancies as otherwise provided in **Chapter 42**

Solid treads and solid landing floors provide a visual barrier that shields the user’s view of the vertical drop beneath the stair. Persons with a fear of high places are more comfortable using such stairs. Grated and expanded metal treads and landings might catch a user’s heel and present a tripping hazard. Noncombustible, grated stair treads are permitted in areas not accessed by the general public, such as catwalks and gridirons in theaters, resident housing areas in prisons, factories and other industrial occupancies, and storage occupancies.

The Code does not directly mandate solid risers on stairs. Rather, the requirement of **7.2.2.3.3.2** for treads to be free of projections or lips that could trip stair users is a performance-based provision that indirectly mandates solid risers on egress stairs used in the upward direction. The prohibition on lips that could trip stair users has application to users moving upward on the stair as well as those moving downward on the stair. **Exhibit 7.80** shows a stair user moving downward on the stair where the lip or nosing catches the stair user’s heel.

**Exhibit 7.80**

Tread nosing catches stair user’s heel. (Photo courtesy of Jake Pauls)

Given that a riser is provided, the maximum slope specified by **7.2.2.3.3.4** — established as 30 degrees from the vertical with not more than a 1½ in. (38 mm) nosing projection — is intended to keep the toes of ascending users from becoming caught under the tread if users have a disability that prevents them from pulling their foot backwards to clear the lip created by the stair tread. The provision of **7.2.2.3.3.4** does not apply to existing stairs.

**7.2.2.3.4\* Tread and Landing Slope.** The tread and landing slope shall not exceed ¼ in./ft (21 mm/m) (a slope of 1 in 48).

**A.7.2.2.3.4** A small drainage slope for stair treads subject to wetting can improve tread slip resistance (*see also A.7.2.2.3.3.2*). A consistent slope to a side of the stair, where drainage is possible, might be preferable to a front-to-back slope of the treads. Providing a pitch of  $\frac{1}{8}$  in./ft to  $\frac{1}{4}$  in./ft (10 mm/m to 21 mm/m) aids the shedding of water from a nominally horizontal surface.

Sloping treads and landings are intentionally used to avoid water accumulation on stairs. They might also be unintentionally created where treads and landings erode unevenly through usage or where differential settlement occurs, affecting the treads or landings. The limitation in slope is intended to reduce the dimensional nonuniformity of the effective riser heights and to reduce the chance of occupants slipping.

**7.2.2.3.5\* Riser Height and Tread Depth.** Riser height shall be measured as the vertical distance between tread nosings. Tread depth shall be measured horizontally, between the vertical planes of the foremost projection of adjacent treads and at a right angle to the tread's leading edge, but shall not include beveled or rounded tread surfaces that slope more than 20 degrees (a slope of 1 in 2.75). At tread nosings, such beveling or rounding shall not exceed  $\frac{1}{2}$  in. (13 mm) in horizontal dimension.

**A.7.2.2.3.5** Figure A.7.2.2.3.5(a), Figure A.7.2.2.3.5(b), Figure A.7.2.2.3.5(c), and Figure A.7.2.2.3.5(d) illustrate the method for measuring riser height and tread depth. Stairs that are covered

**Figure A.7.2.2.3.5(a)** Riser Measurement with Tread Slope to Front.

**Figure A.7.2.2.3.5(b)** Riser Measurement with Tread Slope to Back.

with resilient floor coverings might need additional tread depth beyond the minimum specified in the *Code*. Any horizontal projection of resilient covering materials beyond the tread nosing and riser, such as carpet and underlayment, can interfere with users' feet and thereby reduce usable tread depth. At the tread nosing, such resilient covering materials might not be capable of providing stable support for users' feet. Generally, effective tread depth is reduced by the uncompressed thickness of such resilient coverings, and might be further reduced over time if coverings are not well secured, and, consequently, might move forward at the nosings. [See Figure A.7.2.2.3.5(e).]

**Figure A.7.2.2.3.5(c)** Tread Depth.

**Figure A.7.2.2.3.5(d)** Tread Measurement with Stable Support at Leading Edge.

**Figure A.7.2.2.3.5(e)** Tread Measurement with Unstable Stepping Surface at Leading Edge.

Measurement of riser and tread dimensions needs to represent the actual heights and depths experienced by those using the stairs. Therefore, the tread dimension is not to include any part of the tread that is not functional for normal foot placement, especially where the tread slopes more than 20 degrees from the horizontal. Normal placement of the foot onto the step nosings results in an initial contact angle of less than 20 degrees. Therefore, any part of the nosing sloping more than an angle of 20 degrees is ineffective and might create a tripping hazard. The limitation of a ½ in. (13 mm) horizontal dimension for beveling or rounding of the step nosings is also related to tripping hazards. This beveling or rounding also reduces the chance of a slip occurring when the foot initially contacts the nosing during descent of the stair. By following this rule, the designer also achieves acceptable step dimensions, while keeping the space used for the stair to a minimum.

Stair designers should keep in mind the possibility that a stair that was originally installed without floor coverings or with a resilient covering much like sheet vinyl might someday be carpeted, thereby possibly reducing significantly the effective tread depth of the steps. Designing such stairs to provide slightly more than the minimum required tread depth is especially prudent in these cases. In addition, those responsible for maintaining stairs should keep in mind that the addition of resilient coverings might reduce step tread dimensions to below the standard, and the dimensions will be further reduced if the coverings are not installed and maintained tight against the underlying steps.

#### 7.2.2.3.6\* Dimensional Uniformity.

**A.7.2.2.3.6** A relatively common error in much of home stair construction and, more rarely, in other stair construction is a failure to make the landing nosing projection consistent with the projection of all other nosings in the stair flight. Such an error can easily occur if the stair flight is installed as a prefabricated unit where the top landing does not have a comparable nosing and the unit includes nosing projections. This heightens the risk of an overstepping misstep, at the second or third step down, by a person who is descending.

A fairly reliable test of step dimension uniformity is the crouch and sight test, in which the inspector crouches on the landing above a flight of stairs to confirm that all of the nosings, including the landing nosing, line up. Unless there is a rare matched variation in the height of a step riser and in the tread depth, both proportionally larger or smaller than other steps in the flight, such that the internosing slope or pitch is maintained consistent in the flight, the visual alignment of the nosings in the crouch and sight test will indicate dimensional uniformity. Thus, as a first task in any stair inspection, the crouch and sight test should be routinely performed. If the stair does not pass this visual test, careful measurements performed in accordance with 7.2.2.3.5 are essential. If the stair appears to pass this test, indicating that the internosing slope or pitch is consistent, a prudent second, quick test is to measure the internosing distances for each step to confirm their consistency.

Step dimensions or their uniformity should not be measured by simply laying a measuring tape or stick on the tread or against the riser. Such measurements could be misleading and erroneous relative to the criteria set out in 7.2.2.3.5, particularly if nosing projections are not uniform (as addressed in 7.2.2.3.6.5), if treads slope, or if the slopes vary within a stair flight.

The advisory material on the crouch and sight test addressed in the second paragraph of A.7.2.2.3.6 is helpful to anyone who performs a field inspection of a stair. Exhibit 7.81 shows how the crouch and sight test effectively identifies a nonuniformity, related to riser height or tread depth or to riser height *and* tread depth, that occurs at the fifth step from the bottom of the stair flight. Once the problem is identified visually, the extent of non-uniformity can be documented by careful measurement.

**Exhibit 7.81**

*Nonuniformity in tread/riser dimensions identified by crouch and sight test. (Photo courtesy of Jake Pauls)*

**7.2.2.3.6.1** Variation in excess of 3/16 in. (4.8 mm) in the sizes of adjacent tread depths or in the height of adjacent risers shall be prohibited, unless otherwise permitted in 7.2.2.3.6.3.

**7.2.2.3.6.2** The variation between the sizes of the largest and smallest riser or between the largest and smallest tread depths shall not exceed 3/8 in. (9.5 mm) in any flight.

Many accidents have resulted from irregularities in stair geometry from one step to an adjacent step or over an entire run of stairs. There should be no design irregularities. Variations due to construction are permitted, provided that the variation between adjacent treads or adjacent risers does not exceed 3/16 in. (4.8 mm) and that the difference between the largest and smallest riser, as well as the difference between the largest and smallest tread, in any flight of stairs does not exceed 3/8 in. (9.5 mm).

Exhibit 7.82 shows a stair flight with wide variability in tread depth (and potentially riser height), as addressed by 7.2.2.3.6.1 and 7.2.2.3.6.2. The tread depth variations are greater along the left side of the stair.

Exhibit 7.82

Tread depth variations on stair flight. (Photo courtesy of Jake Pauls)

Exhibit 7.83 illustrates a stair that has various nonuniformities or irregularities. Note that the treads are not all uniformly horizontal, and the risers are not all vertical. This situation, which illustrates construction errors, is sometimes encountered with cast-in-place concrete stairs. Exhibit 7.83 shows unacceptable nonuniformities of the dimensions measured in accordance with 7.2.2.3.6.1 and 7.2.2.3.6.2. The nonuniformities measured at the backs of the treads and along the risers might be greater or smaller, depending on how the treads and risers slope.

**7.2.2.3.6.3** Where the bottom or top riser adjoins a sloping public way, walk, or driveway having an established finished ground level and serves as a landing, the bottom or top riser shall be permitted to have a variation in height of not more than 1 in. in every 12 in. (25 mm in every 305 mm) of stairway width.

Exhibit 7.83

Variations in tread and riser dimensions.

**7.2.2.3.6.4** The size of the variations addressed by 7.2.2.3.6.1, 7.2.2.3.6.2, and 7.2.2.3.6.3 shall be based on the nosing-to-nosing dimensions of the tread depths and riser heights, consistent with the measurement details set out in 7.2.2.3.5.

**7.2.2.3.6.5\*** All tread nosings of stairs utilizing the provision of 7.2.2.3.6.3 shall be marked in accordance with 7.2.2.5.4.3. Those portions of the marking stripe at locations where the riser height below the nosing is inconsistent by more than  $\frac{3}{16}$  in. (4.8 mm), relative to other risers in the stair flight, shall be distinctively colored or patterned, incorporating safety yellow, to warn descending users of the inconsistent geometry relative to other steps in the flight.

**A.7.2.2.3.6.5** “Safety yellow” is the widely used, standard color (described in ANSI/NEMA Z535.1, *Standard for Safety Colors*) to be used for a “caution” function, as a solid color or in alternating, angled yellow-black bars or other geometric combination that draws attention beyond merely designating a nosing. Other nosings, not located above nonuniform risers, need only contrast with the remainder of the step and can be of any color providing contrast relative to the remainder of the tread. Note that similar specification of distinctive and contrasting nosing markings is called for in assembly seating aisle stairs (see, respectively, 12.2.5.6.6(7) and 12.2.5.6.10.1). The safety problems of exterior stairs in assembly aisles and adjacent to a sloping public way are similar, as each individual step has to be visually detected in a reliable fashion. In addition, the presence and location of steps with unavoidably nonuniform risers must be effectively communicated, especially when viewed in the descent direction. Widely varying light conditions further heighten the need for such markings.

**7.2.2.3.6.6** The variation in the horizontal projection of all nosings, including the projection of the landing nosing, shall not exceed  $\frac{3}{8}$  in. (9.5 mm) within each stair flight and, for other than existing nosings, shall not exceed  $\frac{3}{16}$  in. (4.8 mm) between adjacent nosings.

Where the riser at the base of a stair abuts sloping public property, such as a public sidewalk, the building owner usually has no right to alter the grade of the public property. Exhibit 7.84 shows a wide stair where the two bottom risers adjoin a sloping walk. Paragraph 7.2.2.3.6.3 accepts a certain minimum across-the-stair slope not in excess of 1 in 12, as shown in Exhibit 7.85. A similar across-the-stair slope is permitted along the top riser.

The provision of 7.2.2.3.6.4 provides for consistency in how the measurements for calculating across-the-stair slope are to be made.

The provision of 7.2.2.3.6.5 requires that all the tread nosings (not just the top or bottom nosing) in a flight of stairs utilizing the across-the-stair slope allowance of 7.2.2.3.6.3 be provided with marking stripes. The text of A.7.2.2.3.6.5 explains the rationale for such requirement. Exhibit 7.86 depicts the required marking stripes, which are visible by stair users in ascending and descending the stairs.

**Exhibit 7.84**

Stair risers adjoining a sloping walk.

**Exhibit 7.86**

Marking stripes to caution stair user of across-the-stair slope.

**Exhibit 7.85**

Permissible across-the-stair slope. (Photo courtesy of Jake Pauls)

An important concept promoted by the requirement of 7.2.2.3.6.6 centers on the words “including the projection of the landing nosing.” A common construction error involves appending a stair flight, whose tread nosing depths are consistent, against a landing that has a nosing with a different depth. The top-of-flight dimensional nonuniformity is a particular problem encountered in home stair construction.

#### 7.2.2.4 Guards and Handrails.

Guards are to help prevent a fall over an open side of a walking surface. Handrails are to help arrest a fall on a stair or ramp. Stair users will not all hold a handrail while moving on a stair, but they

**Exhibit 7.87**

Man moving on stair but not holding handrail. (Photo courtesy of Jake Pauls)

often stay within reach of a handrail. Exhibit 7.87 shows a man moving along a stair, staying within reach of a handrail, but not holding the handrail. Exhibit 7.88 shows a boy arresting a fall on a stair by grabbing a handrail with both hands. Exhibit 7.89 shows both guards and handrails. There are guards at the floor

Exhibit 7.88

Boy arresting fall on stair by grabbing handrail. (Photo courtesy of Jake Pauls)

Exhibit 7.89

Guards and handrails. (Photo courtesy of Jake Pauls)

openings to the floor below, and there are guards and handrails at both sides of the stair.

**Subsection 7.1.8** requires guards along the open sides of means of egress paths where there is a vertical drop of at least 30 in. (760 mm). **Exhibit 7.90** shows a guard at three of the open sides of a floor opening constructed to accommodate an exit access stair that is not enclosed at the upper level. The

Exhibit 7.90

Guards at floor opening.

requirement for the provision of guards is positioned in the general requirements of **Section 7.1**, because the open sides of means of egress paths occur in places other than just stairs. If the requirement of **7.1.8** to provide guards had instead been positioned within the provisions of **7.2.2** for stairs, it might go unnoticed by *Code* users concerned with egress components other than stairs. Thus, the actual requirement to provide guards appears in **7.1.8**, and the details on how to provide guards are positioned within the provisions of **7.2.2.4**.

The requirement for guards at open sides of means of egress has a particular impact on stairs that historically have required only handrails. Guards must be provided on open sides of the stair — including those that “switch back” between adjacent stair flights, regardless of the horizontal distance between those flights. The minimum 42 in. (1065 mm) high guard, as contrasted with the minimum 34 in. (865 mm) handrail, is needed to prevent a ninety-fifth percentile male from falling over the rail upon striking the side of a stair. On switchback flights of stairs, the required guard is intended to keep a person from falling to the adjacent stair flight. See **7.2.2.4.6** for guard details — especially **7.2.2.4.6.2(3)**, which permits existing guards on existing stairs to be a minimum of 30 in. (760 mm) high.

Where the *Code* permits guards to be omitted, specific language is provided. For example, in **12.2.11.1.6**, which applies to new assembly occupancies, guards are exempted on the audience side of stages; raised platforms; and other raised floor areas, such as runways, ramps, and side stages used for entertainment or presentations. Similarly, permanent guards are not required at

vertical openings in the performance area of stages. Nor are guards required in assembly occupancies where the side of an elevated walking surface is required to be open for the normal functioning of special lighting or for the access and use of other special equipment.

NFPA staff members are often asked whether guards can be omitted at the open edge of loading docks. Given that the *Code* provides no specific exemption for loading docks, it is the intent that the general provisions for guards apply. However, **Chapter 4** gives the authority having jurisdiction great latitude in making judgment calls where protection equivalent to that required by the *Code* is provided. Examples of judgment calls made by the AHJ are presented in the three scenarios that follow.

**Scenario 1.** A loading dock is 30 ft (9.1 m) deep [i.e., the building wall is set back 30 ft (9.1 m) from the open edge of the dock]. At the open edge of the dock, there is more than 30 in. (760 mm) of vertical drop to the ground below. The egress system relies on passage along the width of the loading dock as part of the exit discharge leading to the public way. A 44 in. (1120 mm) wide aisle has been stenciled on the floor running parallel to, and adjacent to, the building wall. Building management strictly enforces a policy that keeps the aisle clear at all times. The authority having jurisdiction judges that, in traveling along the designated path, the building occupants never come close to the open edge of the dock and, thus, guards are not required.

**Scenario 2.** The same physical arrangement exists as in scenario 1, but the AHJ inspects the facility and finds stacked materials in the designated aisle and across the depth of the loading dock. During emergency egress, the building occupants would need to travel close to the open edge of the dock to get around the stacked materials. The AHJ judges that, in this case, the guard provisions need to be followed.

**Scenario 3.** The loading dock is only 10 ft (3050 mm) deep. Materials are placed in a haphazard fashion on the dock. There is no designated egress path and, thus, building occupants can be expected to have to travel near the open edge of the dock. The AHJ judges that guards are needed.

#### 7.2.2.4.1 Handrails.

**7.2.2.4.1.1** Stairs and ramps shall have handrails on both sides, unless otherwise permitted in **7.2.2.4.1.5** or **7.2.2.4.1.6**.

**7.2.2.4.1.2** In addition to the handrails required at the sides of stairs by **7.2.2.4.1.1**, both of the following provisions shall apply:

- (1) For new stairs, handrails shall be provided within 30 in. (760 mm) of all portions of the required egress width.
- (2) For existing stairs, handrails shall meet the following criteria:
  - (a) They shall be provided within 44 in. (1120 mm) of all portions of the required egress width.

- (b) Such stairs shall not have their egress capacity adjusted to a higher occupant load than permitted by the capacity factor in **Table 7.3.3.1** if the stair's clear width between handrails exceeds 60 in. (1525 mm).

**7.2.2.4.1.3** Where new intermediate handrails are provided in accordance with **7.2.2.4.1.2**, the minimum clear width between handrails shall be 20 in. (510 mm).

**7.2.2.4.1.4\*** The required egress width shall be provided along the natural path of travel.

**A.7.2.2.4.1.4** The intent of this provision is to place handrails for the required egress width only, regardless of the actual width. The required egress width is provided along the natural path of travel to and from the building. Examples of this requirement are shown in **Figure A.7.2.2.4.1.4**. The reduced intermediate handrail spacing of 60 in. (1525 mm), along with a handrail height within the permissible height limits, allows users to reach and grasp one handrail. Except as noted in **7.2.2.4.2** and **7.2.2.4.4**, handrails are not required on stair landings.

**7.2.2.4.1.5** If a single step or a ramp is part of a curb that separates a sidewalk from a vehicular way, it shall not be required to have a handrail.

**7.2.2.4.1.6** Existing stairs, existing ramps, stairs within dwelling units and within guest rooms, and ramps within dwelling units and guest rooms shall be permitted to have a handrail on one side only.

Handrails are required on each side of new stairs and ramps, but they are not required on landings, except as noted in **7.2.2.4.2** at inside turns on stairs and in **7.2.2.4.5.10** as a short horizontal extension of the stair handrail. Handrails are also required on at least one side of existing stairs. The handrails provide support for people using stairs, act as a feature that stair users can grab to arrest a fall, and can serve as a guide for users if smoke enters the stairway in a quantity sufficient to obscure vision or if the stair lighting system fails.

For handrails to be effective, they must be within reach of each file of people using the stair. **Paragraph 7.2.2.4.1.2(1)** requires intermediate handrails for new stairs such that no portion of the stair is more than a 30 in. (760 mm) horizontal distance from a handrail. **Paragraph 7.2.2.4.1.2(2)(a)** requires intermediate handrails for existing stairs only where the absence of such an intermediate handrail creates a portion of the stair that is more than 44 in. (1120 mm) horizontal distance from a handrail. The maximum 30 in. (760 mm) distance from a point on a new stair to the nearer handrail is based on the fact that people can only reach approximately 24 in. (610 mm) to the side to grasp a handrail and that a person's arms extend from the side of the body, not from the centerline. **Exhibit 7.91** shows people movement on a stair, seen in overhead plan view. The staggered

**Figure A.7.2.4.1.4** Assumed Natural Paths of Travel on Monumental Stairs with Various Handrail Locations.

**Exhibit 7.91**

Overhead plan view of stair with handrails within maximum 30 in. (760 mm) reach.

filling of the stair surfaces is typical of that observed during building evacuation where movement, speed, density, and flow are near optimum for safe, comfortable crowd movement.

Because 7.2.2.2.1.2(A), 7.2.2.2.1.2(B), and 7.3.2.2 permit new handrails to project as much as  $4\frac{1}{2}$  in. (114 mm) into the stair clear width at each side of the stair, center handrails are needed on new stairs more than, approximately, 5 ft 9 in. (1750 mm) wide, or  $4\frac{1}{2}$  in. + 30 in. + 30 in. +  $4\frac{1}{2}$  in. (114 mm + 760 mm + 760 mm + 114 mm), as illustrated in Exhibit 7.92.

Because Table 7.2.2.2.1.1(b) and 7.3.2.2 permit existing handrails to project as much as  $4\frac{1}{2}$  in. (114 mm) into the stair clear width at each side of the stair, center handrails are needed on existing stairs more than, approximately, 8 ft 1 in. (2470 mm) wide, or  $4\frac{1}{2}$  in. + 44 in. + 44 in. +  $4\frac{1}{2}$  in. (114 mm + 1120 mm + 1120 mm + 114 mm), as illustrated in Exhibit 7.93.

Exhibit 7.94 shows a mall building stair, with sufficient width that it would require an intermediate (i.e., center) handrail if constructed to meet the requirements for new stairs. However, it is an existing stair, and its width is not sufficient to require an intermediate handrail. Exhibit 7.95 shows a wide, enclosed exit stair with intermediate handrails.

Paragraph 7.2.2.4.1.2(2)(b) prohibits existing stairways with a clear width between handrails in excess of 60 in. (1525 mm) from using the capacity factor adjustment offered in 7.3.3.2 to stairways wider than 44 in. (1120 mm). The normal stair capacity factor of 0.3 in. (7.6 mm) per person is especially needed where a stair user is more than 30 in. (760 mm) from a handrail, which might have the effect of slowing people movement on the stair.

On monumental stairs, which are characterized by their extreme widths, the required handrails should be located along the normal path of travel to and from the building. Figure A.7.2.4.1.4 illustrates the placement of handrails required on stairs that provide more width than required for egress.

Exhibit 7.92

Maximum required width permitted without center handrail on new stair.

Handrails are provided along the natural paths of travel from the associated door assemblies. Additionally, handrails are required at both sides of a new stair in accordance with the provisions of 7.2.2.4.1.1 and 7.2.2.4.1.6.

The provision of 7.2.2.4.1.6 is difficult to understand with its string of conditions separated by commas. The net effect is to permit a handrail at only one side of a stair or ramp under the following conditions:

1. Existing stairs regardless of occupancy
2. Existing ramps regardless of occupancy

Exhibit 7.93

Maximum required width permitted without center handrail on existing stair.

3. New and existing stairs within dwelling units and within guest rooms
4. New and existing ramps within dwelling units and within guest rooms

**7.2.2.4.2 Continuity.** Required guards and handrails shall continue for the full length of each flight of stairs. At turns of new stairs, inside handrails shall be continuous between flights at landings.

It is not the intent of this Code to require handrails on stair landings. However, new handrails on the inside turn of switchback stairs (stairs that change direction at a landing) must be

Exhibit 7.94

Existing stair width that does not require intermediate handrail.  
(Photo courtesy of Jake Pauls)

Exhibit 7.95

Enclosed exit stair with intermediate handrails.

continuous. Exhibit 7.96 shows a continuous handrail on the inside turn of a stair at a landing. A similar turn is detailed in the plan view of Figure A.7.2.2.4.4.

The commentary following 7.2.2.4 explains the need for guards on open sides of stairs where there is at least a 30 in. (760 mm) vertical drop. The 30 in. (760 mm) criterion — considered alone — would seem to exempt the guard from running alongside the last couple of risers at the base of each stair flight; however, this criterion must be considered in conjunction with 7.2.2.4.2, which mandates that the required guard is to continue for the full length of each flight of stairs.

Exhibit 7.96

Continuous handrail on inside turn of stair at landing. (Photo courtesy of Jake Pauls)

Exhibit 7.97

Center handrail C provided at a right angle to the leading edge of the stair treads.

**7.2.2.4.3 Projections.** The design of guards and handrails and the hardware for attaching handrails to guards, balusters, or walls shall be such that there are no projections that might engage loose clothing. Openings in guards shall be designed to prevent loose clothing from becoming wedged in such openings.

**7.2.2.4.4 Direction.** For standard stairs, at least one handrail shall be installed at a right angle to the leading edge of the stair treads.

The provision of 7.2.2.4.4 is new to the 2015 edition of the Code. Exhibit 7.97 depicts a new stair where handrails A and E, which are provided at each side of the stair for compliance with 7.2.2.4.1.1, are at other than a right angle to the leading edge of

**Exhibit 7.98***Anthropometric analysis of reach.*

heights — even for elderly persons tested — were in the range of 36 in. to 38 in. (915 mm to 965 mm), and the average height most preferred by elderly persons tested was about 37 in. (940 mm). These studies were reported in “Review of Stair-Safety Research with an Emphasis on Canadian Studies” by Jake Pauls.<sup>12</sup> The recommendation for lower handrails for young children is particularly important for family dwellings and for child day-care facilities.

**Exhibit 7.99** is a frame from the documentary film, *The Stair Event*. It shows field testing of an adjustable-height handrail in

**Exhibit 7.99***Field testing of handrail height. (Photo courtesy of Jake Pauls)*

an aisle stair in Canada’s Edmonton Commonwealth Stadium. Evidence from such field testing, from anthropometric analyses, and from laboratory testing with a range of younger and older adults, led to the higher handrail heights first introduced in the 1988 edition of the *Code*. The upper handrail is located 37 in. (940 mm) above tread nosings, which, in the laboratory testing, was the average preferred height for elderly people and an especially effective height for arresting a fall that occurs while descending a stair. The lower railing, provided for children, is approximately 24 in. (610 mm) above the tread nosings. Note that, even in this case of ascent, one of the children has chosen to use the higher railing, located at about his shoulder height, in preference to the lower one. A moment after this frame was taken, the smaller of the two boys also chose to use the upper handrail, which was located at about the height of his head. This behavior has been observed in other studies of children; that is, when given a choice of handrail heights, they often select one between shoulder and head height.

**Exhibit 7.100** shows a stair with an additional handrail, as permitted by 7.2.2.4.5.4, mounted at a lower height than the handrail installed for compliance with 7.2.2.4.5.1.

**7.2.2.4.5.5** New handrails shall be installed to provide a clearance of not less than 2¼ in. (57 mm) between the handrail and the wall to which it is fastened.

In earlier editions of the *Code*, a minimum 1½ in. (38 mm) clearance was required between a new handrail and the wall to which it was fastened. The current provision, as detailed in 7.2.2.4.5.5, increases the required minimum clearance to 2¼ in. (57 mm) for new handrails in recognition of the fact that 1½ in. (38 mm) is an inadequate clearance for both a normal grasp and an emergency grasp of the handrail. **Exhibit 7.101** depicts the required 2¼ in. (57 mm) finger clearance.

**Exhibit 7.100***Additional handrail mounted at lower height than standard handrail. (Photo courtesy of Jake Pauls)*

**Exhibit 7.101**

Required finger clearance between handrail and wall.

**7.2.2.4.5.6** Handrails shall include one of the following features:

- (1) Circular cross section with an outside diameter of not less than 1¼ in. (32 mm) and not more than 2 in. (51 mm)
- (2)\* Shape that is other than circular with a perimeter dimension of not less than 4 in. (100 mm), but not more than 6¼ in. (160 mm), and with the largest cross-sectional dimension not more than 2¼ in. (57 mm), provided that graspable edges are rounded so as to provide a radius of not less than ⅛ in. (3.2 mm)

**A.7.2.2.4.5.6(2)** Handrails should be designed so they can be grasped firmly with a comfortable grip and so the hand can slid along the rail without encountering obstructions. The profile of the rail should comfortably match the hand grips. For example, a round profile, such as is provided by the simplest round tubing or pipe having an outside diameter of 1½ in. to 2 in. (38 mm to 51 mm), provides good graspability for adults. Factors such as the use of a handrail by small children and the wall-fixing details should be taken into account in assessing handrail graspability. The most functional, as well as the most preferred, handrail shape and size is circular with a 1½ in. (38 mm) outside diameter (according to research conducted using adults). Handrails used predominantly by children should be designed at the lower end of the permitted dimensional range.

Handrails are one of the most important components of a stair; therefore, design excesses such as oversized wood handrail sections should be avoided, unless there is a readily perceived and easily grasped handhold provided. In handrail design, it is useful to remember at all times the effectiveness of a simple round profile that allows some locking action by fingers as they curl around and under the handrail.

Perimeter dimension, referred to in **7.2.2.4.5.6(2)**, is the length of the shortest loop that wraps completely around the railing.

**Paragraph 7.2.2.4.5.6** introduces a subtle but important requirement for handrails — graspability. People are incapable of exerting sufficient finger pressure to grasp a handrail adequately where using only a pinch grip; a power grip, where fingers curl

around and under a properly shaped and sized railing, is much more effective. **Exhibit 7.102** shows a power grip on a handrail circular cross section, as addressed in **7.2.2.4.4.6(1)**. **Exhibit 7.103** and **Exhibit 7.104** show a power grip on handrail sections of other than circular shape, as addressed in **7.2.2.4.4.6(2)**. **Exhibit 7.105** shows a pinch grip on a handrail that is not graspable.

**Exhibit 7.102**

Exhibit 7.104

Graspable handrail of other than circular shape — Example 2 of 2. (Photo courtesy of Jake Pauls)

Exhibit 7.105

Nongraspable handrail requiring pinch grip. (Photo courtesy of Jake Pauls)

**7.2.2.4.5.7** New handrails shall be continuously graspable along their entire length.

The handrails shown in [Exhibit 7.106](#) are dramatic in appearance but create obstacles to continuous graspability.

Exhibit 7.106

Handrail with repeated obstacles to continuous graspability. (Photo courtesy of Jake Pauls)

**7.2.2.4.5.8** Handrail brackets or balusters attached to the bottom surface of the handrail shall not be considered to be obstructions to graspability, provided that both of the following criteria are met:

- (1) They do not project horizontally beyond the sides of the handrail within 1½ in. (38 mm) of the bottom of the handrail and provided that, for each additional ½ in. (13 mm) of handrail perimeter dimension greater than 4 in. (100 mm), the vertical clearance dimension of 1½ in. (38 mm) is reduced by ⅛ in. (3.2 mm).
- (2) They have edges with a radius of not less than 0.01 in. (0.25 mm).

**Paragraph 7.2.2.4.5.8** recognizes that handrail brackets and other forms of support are necessary but need to be designed to allow the hand to slide along the handrail without encountering obstructions that would force the release of the hand's grip. [Exhibit 7.107](#) shows a handrail that has been positioned above the horizontal extension of the supporting bracket by the required minimum 1½ in. (38 mm). Note how the fingers of the hand have sufficient space to point downward in a natural grasping position without encountering the handrail bracket.

**7.2.2.4.5.9** New handrail ends shall be returned to the wall or floor or shall terminate at newel posts.

**Exhibit 7.107***Minimum clearance to handrail brackets.*

**7.2.2.4.5.10** In other than dwelling units, new handrails that are not continuous between flights shall extend horizontally, at the required height, not less than 12 in. (305 mm) beyond the top riser and continue to slope for a depth of one tread beyond the bottom riser.

**7.2.2.4.5.11** Within dwelling units, handrails shall extend, at the required height, to at least those points that are directly above the top and bottom risers.

The handrail extensions required by **7.2.2.4.5.10** are depicted in **Figure A.7.2.2.4.5**. At the top of the stair, the handrail extends horizontally for at least 12 in. (305 mm) past the top riser; at the bottom of the stair, the handrail continues past the bottom riser but does so at the same sloped angle as the remainder of the handrail positioned over the stair treads. The handrail extensions allow the stair users, who want to hold the handrail continuously while traveling along the stair, to grasp the handrail at their side — rather than ahead — before beginning to move vertically on the stair, and to continue to grasp the handrail at their side until vertical movement on the stair has been completed.

**Paragraph 7.2.2.4.5.11** recognizes that the handrail extensions required by **7.2.2.4.5.10** need space at the top and bottom of stair flights that is typically not provided within dwelling units (e.g., hotel guest suites, apartment units, and single-family homes). It also recognizes that fewer occupants are expected to use a stair within a dwelling unit than a stair in the common space of a building (e.g., an enclosed exit stair serving the upper floors of a large apartment building). The provision permits handrails on stairs within dwelling units to end at points directly above the top and bottom risers. Where the stair users want to hold the handrail continuously while traveling along the stair, the users will need to reach forward to grasp the handrail before beginning to move vertically and will end their travel with their arm extended behind the plane of their backs.

**7.2.2.4.6 Guard Details.** See **7.1.8** for guard requirements.

**7.2.2.4.6.1** The height of guards required in **7.1.8** shall be measured vertically to the top of the guard from the surface adjacent thereto.

**7.2.2.4.6.2** Guards shall be not less than 42 in. (1065 mm) high, except as permitted by one of the following:

- (1) Existing guards within dwelling units shall be permitted to be not less than 36 in. (915 mm) high.
- (2) The requirement of **7.2.2.4.6.2** shall not apply in assembly occupancies where otherwise provided in **Chapters 12 and 13**.
- (3)\* Existing guards on existing stairs shall be permitted to be not less than 30 in. (760 mm) high.

**A.7.2.2.4.6.2(3)** This reduction in required height applies only to the stair, not to the landings.

The criterion for a 6 in. (150 mm) diameter sphere was changed to a 4 in. (100 mm) diameter sphere for the 1991 edition of the *Code*. This change was made based on the submission of a proposal that received the backing of the American Academy of Pediatrics. Approximately 950 out of 1000 children under age 10 can pass through a 6 in. (150 mm) wide opening. To prevent small children from falling through guards or being caught in openings, the configuration and construction of a guard must meet certain minimum requirements. Rather than requiring detailed specifications to be met for intermediate rails, the *Code* sets a performance criterion that permits alternative solutions.

The 4 in. (100 mm) diameter sphere criterion applies only to the portion of the guard that extends from the walking surface to a height of 34 in. (865 mm), even though the top rail of the guard must extend to a minimum height of 42 in. (1065 mm). See **Exhibit 7.108**.

**Exhibit 7.108***Height extension for application of 4 in. (100 mm) diameter sphere criterion for guards.*

**Paragraph 7.2.2.4.6.3** exempts approved existing open guards from the maximum 4 in. (100 mm) diameter sphere criterion. Note that the phrase “approved existing open guards” has a different meaning than the phrase “previously approved open guards.” See **3.3.81.1** and **3.3.214**. In evaluating whether existing guards that do not meet the maximum 4 in. (100 mm) diameter sphere criterion are to be permitted to continue in use, it does not matter whether such guards received prior approval from the authority having jurisdiction. Instead, approval by the current AHJ is needed. Consider the following three examples:

1. The AHJ examines the existing open guards and finds that they meet a 6 in. (150 mm) diameter sphere criterion. The AHJ knows that older editions of the *Code* mandated a maximum 6 in. (150 mm) spacing and, therefore, approves the existing installation for continued use.
2. The AHJ examines the existing open guards and finds that they meet a 20 in. (510 mm) diameter sphere criterion. The AHJ knows that older editions of the *Code* did not permit anything larger than 6 in. (150 mm) spacing and, therefore, does not approve the existing installation for continued use.
3. The AHJ examines the existing open guards and finds that they meet an 8 in. (205 mm) diameter sphere criterion. The AHJ knows that older editions of the *Code* did not permit anything larger than 6 in. (150 mm) spacing and makes a judgment call on whether to approve the existing installation for continued use.

**Paragraph A.7.2.2.4.6.3** advises that vertical intermediate rails in guards are preferred to reduce climbability as presented by horizontal rails. **Exhibit 7.109** shows a guard system, on the stair landings and along the sides of the stair, with horizontal rails that are climbable.

**7.2.2.4.6.3\*** Open guards, other than approved existing open guards, shall have intermediate rails or an ornamental pattern such that a sphere 4 in. (100 mm) in diameter is not able to pass through any opening up to a height of 34 in. (865 mm), and the following also shall apply:

- (1) The triangular openings formed by the riser, tread, and bottom element of a guardrail at the open side of a stair shall be of such size that a sphere 6 in. (150 mm) in diameter is not able to pass through the triangular opening.
- (2) In detention and correctional occupancies, in industrial occupancies, and in storage occupancies, the clear distance between intermediate rails, measured at right angles to the rails, shall not exceed 21 in. (535 mm).

**A.7.2.2.4.6.3** Vertical intermediate rails are preferred to reduce climbability.

## 7.2.2.5 Enclosure and Protection of Stairs.

### 7.2.2.5.1 Enclosures.

**7.2.2.5.1.1** All inside stairs serving as an exit or exit component shall be enclosed in accordance with **7.1.3.2**.

**Exhibit 7.109**

Horizontal rails in guard system that facilitate climbing. (Photo courtesy of Jake Pauls)

**7.2.2.5.1.2** Inside stairs, other than those serving as an exit or exit component, shall be protected in accordance with **Section 8.6**.

**7.2.2.5.1.3** In existing buildings, where a two-story exit enclosure connects the story of exit discharge with an adjacent story, the exit shall be permitted to be enclosed only on the story of exit discharge, provided that not less than 50 percent of the number and capacity of exits on the story of exit discharge are independent of such enclosures.

**Paragraphs 7.2.2.5.1.1** and **7.2.2.5.1.2** emphasize that enclosure protection for stairs depends on whether they serve within an exit or involve a vertical opening between floors. Stairs that are not used as exits but that involve vertical openings are not subject to the requirements of **7.1.3.2**; they must be protected in accordance with **Section 8.6**. Many interior stairs serve as exits and are vertical openings — they must, therefore, meet the requirements of **7.1.3.2** for exits as well as those of **Section 8.6**. Compliance with **Section 8.6** does not ensure compliance with **7.1.3.2**. Stairs that are neither within an exit nor part of vertical openings, such as stairs to a platform or stage, or those running between two different floor levels on the same story, do not have to comply with either **7.1.3.2** or **Section 8.6**.

The provisions of **7.2.2.5.1.3** recognize existing two-story stairs that, rather than being fully enclosed by a fire-rated shaft

**Exhibit 7.110**

*Partial enclosure of existing stair.*

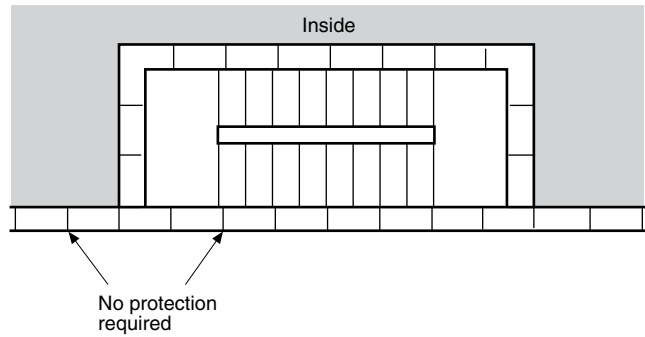

at both the top and bottom, are separated only from the level of exit discharge. Because such stairs are open to another floor, they might compromise the use of the stair enclosure for egress purposes by occupants of the level of exit discharge. The Code requires that at least half of the egress for the level of exit discharge be independent of the stair enclosure. This requirement limits the effect of occupants who are forced to travel into an enclosure that is smoke-filled due to a fire on another floor that is open to the stair. In Exhibit 7.110, the existing stair connecting the first and second floors, although separated from the first floor, is open to the second floor. This arrangement is permitted because a minimum of 50 percent of the first floor egress can be satisfied independently from use of the stair enclosure via the door assembly that opens directly to the outside at grade level at the right of the exhibit.

**7.2.2.5.2\* Exposures.**

**A.7.2.2.5.2** The purpose of this provision is to protect the exterior wall of a stairway from fires in other portions of the building. If the exterior wall of the stair is flush with the building exterior wall, the fire would need to travel around 180 degrees in order to impact the stair. This has not been a problem in existing buildings, so no protection is required. However, if the angle of exposure is less than 180 degrees, protection of either the stair wall or building wall is required.

Figure A.7.2.2.5.2(a), Figure A.7.2.2.5.2(b), and Figure A.7.2.2.5.2(c) illustrate the requirement, assuming nonrated glass on the exterior wall of the stair is used.

**7.2.2.5.2.1** Where nonrated walls or unprotected openings enclose the exterior of a stairway, other than an existing stairway, and the walls or openings are exposed by other parts of

**Figure A.7.2.2.5.2(a)** Stairway with Nonrated Exterior Wall in Same Plane as Building Exterior Wall.

**Figure A.7.2.2.5.2(b)** Stairway with Unprotected Exterior Perimeter Protruding Past Building Exterior Wall.

**Figure A.7.2.2.5.2(c)** Stairway with Nonrated Exterior Wall Exposed by Adjacent Exterior Wall of Building.

the building at an angle of less than 180 degrees, the building enclosure walls within 10 ft (3050 mm) horizontally of the non-rated wall or unprotected opening shall be constructed as required for stairway enclosures, including opening protectives.

**7.2.2.5.2.2** Construction shall extend vertically from the finished ground level to a point 10 ft (3050 mm) above the topmost landing of the stairs or to the roofline, whichever is lower.

**7.2.2.5.2.3** The fire resistance rating of the separation extending 10 ft (3050 mm) from the stairs shall not be required to exceed 1 hour where openings have a minimum ¾-hour fire protection rating.

The provisions of 7.2.2.5.2.1 through 7.2.2.5.2.3 are well explained by A.7.2.2.5.2, including Figure A.7.2.2.5.2(a), Figure A.7.2.2.5.2(b), and Figure A.7.2.2.5.2(c).

**7.2.2.5.3\* Usable Space.** Enclosed, usable spaces within exit enclosures shall be prohibited, including under stairs, unless otherwise permitted by 7.2.2.5.3.2.

**A.7.2.2.5.3** An example of a use with the potential to interfere with egress is storage.

**7.2.2.5.3.1** Open space within the exit enclosure shall not be used for any purpose that has the potential to interfere with egress.

**7.2.2.5.3.2** Enclosed, usable space shall be permitted under stairs, provided that both of the following criteria are met:

- (1) The space shall be separated from the stair enclosure by the same fire resistance as the exit enclosure.
- (2) Entrance to the enclosed, usable space shall not be from within the stair enclosure. (See also 7.1.3.2.3.)

Paragraphs 7.2.2.5.3 and 7.2.2.5.3.1 state that, within an exit enclosure, no enclosed, usable space is permitted, nor is any open space permitted to be used for any purpose that could interfere with the use of the exit enclosure. Per 7.2.2.5.3.2, an enclosed, usable space under a stair is permitted to be considered outside the exit enclosure if the walls and soffits of the enclosed space meet the same protection requirements as the stair enclosure, thereby separating the space from the exit enclosure, and if the door assembly to the space does not open into the exit enclosure. The provision of 7.2.2.5.3.2 is depicted in Exhibit 7.111. Note that fire resistance-rated construction isolates the space beneath the last run of stair so that the space is no longer within the exit enclosure. Note also that a door assembly that is outside the exit enclosure is used to enter the space, as a door communicating between the space and the exit enclosure would violate the provision of 7.1.3.2.1(9).

**7.2.2.5.4\* Stairway Identification.**

**A.7.2.2.5.4** Figure A.7.2.2.5.4 shows an example of a stairway marking sign.

Exhibit 7.111

Enclosed, usable space under flight of stairs.

**7.2.2.5.4.1** New enclosed stairs serving three or more stories and existing enclosed stairs, other than those addressed in 7.2.2.5.4.1(P), serving five or more stories shall comply with 7.2.2.5.4.1(A) through 7.2.2.5.4.1(O).

(A) The stairs shall be provided with special signage within the enclosure at each floor landing.

(B) The signage shall indicate the floor level.

(C) The signage shall indicate the terminus of the top and bottom of the stair enclosure.

(D) The signage shall indicate the identification of the stair enclosure.

**NORTH STAIR  
FLOOR**

5

**SUB-BASEMENT TO 24TH FLOOR  
NO ROOF ACCESS  
DOWN TO FIRST FLOOR  
FOR EXIT DISCHARGE**

Figure A.7.2.2.5.4 Example of a Stairway Marking Sign.

(E) The signage shall indicate the floor level of, and the direction to, exit discharge.

(F) The signage shall be located inside the stair enclosure.

(G) The bottom of the signage shall be located a minimum of 48 in. (1220 mm) above the floor landing, and the top of the signage shall be located a maximum of 84 in. (2135 mm) above the floor landing

(H) The signage shall be in a position that is visible when the door is in the open or closed position.

(I) The signage shall comply with 7.10.8.1 and 7.10.8.2 of this Code.

(J) The floor level designation shall also be tactile in accordance with ICC/ANSI A117.1, *American National Standard for Accessible and Usable Buildings and Facilities*.

(K) The signage shall be painted or stenciled on the wall or on a separate sign securely attached to the wall.

(L) The stairway identification shall be located at the top of the sign in minimum 1 in. (25 mm) high lettering and shall be in accordance with 7.10.8.2.

(M)\* Signage that reads NO ROOF ACCESS shall designate stairways that do not provide roof access. Lettering shall be a minimum of 1 in. (25 mm) high and shall be in accordance with 7.10.8.2.

**A.7.2.2.5.4.1(M)** It is not the intent to require a sign that reads ROOF ACCESS, as such message might be misinterpreted by building occupants as an alternative egress route. However signs that read ROOF ACCESS are not prohibited, as many such signs have been installed in existing buildings so as to make a requirement for removal impractical. Historically, the ROOF ACCESS sign has provided information for the fire department. Where there is no roof access, such information will be posted via a NO ROOF ACCESS sign. The absence of the NO ROOF ACCESS sign should be understood by the fire department to mean that roof access is possible.

(N) The floor level number shall be located below the stairway identifier in minimum 5 in. (125 mm) high numbers and shall be in accordance with 7.10.8.2. Mezzanine levels shall have the letter “M” or other appropriate identification letter preceding the floor number, while basement levels shall have the letter “B” or other appropriate identification letter preceding the floor level number.

(O) Identification of the lower and upper terminus of the stairway shall be on the sign in minimum 1 in. (25 mm) high letters or numbers and shall be in accordance with 7.10.8.2.

(P) Previously approved, existing signage shall not be required to comply with 7.2.2.5.4.1(L) through (O).

The provisions of 7.2.2.5.4.1 require the posting of important information at each floor landing in each stairwell if a new stair

serves three or more stories or an existing stair serves five or more stories. The information is for fire-fighting personnel and building occupants in an emergency. The term *signage* is used to signify that the required information might appear on multiple signs mounted adjacent to each other. The information most helpful to fire fighters can be put on one sign, and the information most useful to occupants on another. See Figure A.7.2.2.5.4.

The signage must identify the stair, indicate the floor level of the landing [this element additionally must be tactile per 7.2.2.5.4.1(J)] and where the stairwell terminates at the top and bottom, and identify and show the direction to the exit discharge. Exhibit 7.112 illustrates the placement required to ensure that the sign is readily visible, whether the door leaf is open or closed.

Exhibit 7.112

Stair sign placement.

The indication of the direction to the level of exit discharge can be extremely useful to occupants of a building, especially if they are located below the level of exit discharge. The natural tendency of occupants is to attempt egress by traveling downward in a stair; this is counterproductive where the exit discharge is located on an upper level. Also, many buildings have multiple levels of entrance, which create confusion with respect to travel direction in a given stair.

The requirements of 7.2.2.5.4 are not exempted for existing buildings, because it is feasible and cost-effective to install signs providing the required information. Because stair enclosures are usually not as aesthetically well finished as occupied portions of a building, the requirement for the signage (other than for the tactile floor level designator) is often met by stenciling the information directly onto the walls.

The provision of 7.2.2.5.4.1(M) was revised for the 2009 edition of the *Code*. In prior editions, roof access or lack of roof access was required to be designated by a sign. In many cases, roof access was provided for emergency responders only, and a sign reading “Roof Access” was misleading to building occupants. The current provision requires that only the lack of roof access be designated by a sign.

The provision of 7.2.2.5.4.1(G) is new to the 2015 edition of the *Code*. It replaces a provision that required the signage to be located approximately 60 in. (1525 mm) above the floor landing. The *Code* user now has a definitive height range for placement of the sign above the floor landing. Other criteria were moved or combined for clarification. The provision of 7.2.2.5.4.1(P) was added so that signs installed prior to 2009, when subitems (L) through (O) were added, are not unfairly reclassified as noncompliant.

Exhibit 7.113 shows a stairway identification sign with the information required by 7.2.2.5.4.1. The element reading *Level 2* was provided for compliance with 7.2.2.5.4.1(B), which requires that the signage indicate the floor level, and for compliance with 7.2.2.5.4.1(J), which requires that the floor level designation also be tactile in accordance with ICC/ANSI A117.1, *American National*

Exhibit 7.113

Stairway identification sign with tactile floor level designator.

*Standard for Accessible and Usable Buildings and Facilities*. The minimum 5 in. (125 mm) high floor level number — the large 2 in this case — that was provided for compliance with 7.2.2.5.4.1(N) cannot serve as the tactile floor level designation because ICC/ANSI A117.1 limits raised characters to being not more than 2 in. (51 mm) in height. Further, the floor level designation is provided in braille below the tactile element, as ICC/ANSI A117.1 requires that raised letters be duplicated in braille.

**7.2.2.5.4.2** Wherever an enclosed stair requires travel in an upward direction to reach the level of exit discharge, special signs with directional indicators showing the direction to the level of exit discharge shall be provided at each floor level landing from which upward direction of travel is required, unless otherwise provided in 7.2.2.5.4.2(A) and 7.2.2.5.4.2(B), and both of the following also shall apply:

- (1) Such signage shall comply with 7.10.8.1 and 7.10.8.2.
- (2) Such signage shall be visible when the door leaf is in the open or closed position.

(A) The requirement of 7.2.2.5.4.2 shall not apply where signs required by 7.2.2.5.4.1 are provided.

(B) The requirement of 7.2.2.5.4.2 shall not apply to stairs extending not more than one story below the level of exit discharge where the exit discharge is clearly obvious.

**7.2.2.5.4.3\* Stairway Tread Marking.** Where new contrasting marking is applied to stairs, such marking shall comply with all of the following:

- (1) The marking shall include a continuous strip as a coating on, or as a material integral with, the full width of the leading edge of each tread.
- (2) The marking shall include a continuous strip as a coating on, or as a material integral with, the full width of the leading edge of each landing nosing.
- (3) The marking strip width, measured horizontally from the leading vertical edge of the nosing, shall be consistent at all nosings.
- (4) The marking strip width shall be 1 in. to 2 in. (25 mm to 51 mm).

**A.7.2.2.5.4.3** Where environmental conditions (such as illumination levels and directionality or a complex visual field that draws a person’s attention away from stair treads) lead to a hazardous reduction in one’s ability to perceive stair treads, they should be made of a material that allows ready discrimination of the number and position of treads. In all cases, the leading edges of all treads should be readily visible during both ascent and descent. A major factor in injury-producing stair accidents, and in the ability to use stairs efficiently in conditions such as egress, is the clarity of the stair treads as separate stepping surfaces.

For stair nosing marking, surface-applied material, such as adhesive-backed tape and magnetic strips, should not be used, as it is not durable under the scuffing from users’ feet and, in coming loose, it creates a tripping hazard. While a carefully

applied and consistently maintained coating is acceptable, contrasting color or photoluminescent material integral with the nosings is preferable because of its permanence. It is also the intent of 7.2.2.5.4.3 to require the contrasting stairway tread marking to be a material integral with the stair tread and not a material integral with a stair nosing product that is installed on the stair tread. See also 7.1.6.4 and 7.2.2.3.6 for slip resistance uniformity requirements, as well as prohibition of projections on the treads.

Guidance on the use of photoluminescent marking is provided by ASTM E 2030, Standard *Guide for Recommended Uses of Photoluminescent (Phosphorescent) Safety Markings*. Additional marking, for example, at the side boundaries of the stair, should be applied in accordance with the guidance provided therein.

**7.2.2.5.4.4\*** Where new contrast marking is provided for stairway handrails, it shall be applied to, or be part of, at least the upper surface of the handrail; have a minimum width of ½ in. (13 mm); and extend the full length of each handrail. After marking, the handrail shall comply with 7.2.2.4.5. Where handrails or handrail extensions bend or turn corners, the stripe shall be permitted to have a gap of not more than 4 in. (100 mm).

**A.7.2.2.5.4.4** Coatings and other applied markings, if used, should be durable for the expected usage, especially at end terminations of the marking and at changes in stair direction where usage is more extensive and hand forces are larger.

The criteria of 7.2.2.5.4.3(1) through (4) are needed to prevent the marking strips from providing misleading cues to stair users that might make use of the stair less safe or more confusing than if the marking strips were not installed. For example, 7.2.2.5.4.3(4) limits the marking strip to a maximum width of 2 in. (51 mm) to ensure that all but the leading edge of the tread is left unmarked, so a person using the stair in the downward direction sees individual tread edges and not one continuously marked sloping plane. The undesired continuously marked sloping plane would create a ramp effect, with no indication of the location of the leading edge of each tread. Exhibit 7.114 shows an outside stair where tread marking provided by paint application has worn away to the point that the tread locations are imperceptible.

The provisions of 7.2.2.5.4.4 do not mandate that contrasting marking be applied to stair handrails. Where such contrast marking is provided for handrails, it regulates such installation so that the markings are useful and not misleading. For example, it requires that the marking stripe extend the full length of each handrail so the stair user can assess the extent of the stair flight before beginning any vertical movement on the stair.

Contrast marking, where applied, will usually be in the form of a photoluminescent or glow-in-the-dark material. See 7.2.2.5.5.10. The third sentence of 7.2.2.5.4.4 was new to the 2012 edition of the Code. It permits short gaps in the contrast marking striping at handrail bends and turns in recognition of the fact that some photoluminescent materials are too rigid to be applied effectively at bends and turns.

Exhibit 7.114

Stair tread marking worn away so as to make tread location imperceptible. (Photo courtesy of Jake Pauls)

**7.2.2.5.5 Exit Stair Path Markings.** Where exit stair path markings are required in Chapters 11 through 43, such markings shall be installed in accordance with 7.2.2.5.5.1 through 7.2.2.5.5.11.

**7.2.2.5.5.1\* Exit Stair Treads.** Exit stair treads shall incorporate a marking stripe that is applied as a paint/coating or be a material that is integral with the nosing of each step.

(A) The marking stripe shall be installed along the horizontal leading edge of the step and shall extend the full width of the step.

(B) The marking stripe shall also meet all of the following requirements:

- (1) The marking stripe shall be not more than ½ in. (13 mm) from the leading edge of each step and shall not overlap the leading edge of the step by more than ½ in. (13 mm) down the vertical face of the step.
- (2) The marking stripe shall have a minimum horizontal width of 1 in. (25 mm) and a maximum width of 2 in. (51 mm).
- (3) The dimensions and placement of the marking stripe shall be uniform and consistent on each step throughout the exit enclosure.
- (4) Surface-applied marking stripes using adhesive-backed tapes shall not be used.

**A.7.2.2.5.5.1** Exit stair treads are required to incorporate a marking stripe that is applied as a paint/coating or be a material that is integral with the nosing of each step. It is the intent of this provision to require the contrasting stairway tread marking to be a material integral with the stair tread and not a material integral with a stair nosing product that is installed on the stair tread. See also 7.1.6.4 and 7.2.2.3.6 for slip resistance requirements, as well as 7.2.2.3.3.2, which prohibits tread projections.

**7.2.2.5.5.2 Exit Stair Landings.** The leading edge of exit stair landings shall be marked with a solid and continuous marking stripe consistent with the dimensional requirements for stair treads and shall be the same length as, and consistent with, the stripes on the steps.

**7.2.2.5.5.3 Exit Stair Handrails.** All handrails and handrail extensions shall be marked with a solid and continuous marking stripe and meet all of the following requirements:

- (1) The marking stripe shall be applied to the upper surface of the handrail or be a material integral with the upper surface of the handrail for the entire length of the handrail, including extensions.
- (2) Where handrails or handrail extensions bend or turn corners, the marking stripe shall be permitted to have a gap of not more than 4 in. (100 mm).
- (3) The marking stripe shall have a minimum horizontal width of 1 in. (25 mm), which shall not apply to outlining stripes listed in accordance with ANSI/UL 1994, *Standard for Luminous Egress Path Marking Systems*.
- (4) The dimensions and placement of the marking stripe shall be uniform and consistent on each handrail throughout the exit enclosure.

**7.2.2.5.5.4 Perimeter Demarcation Marking.** Stair landings, exit passageways, and other parts of the floor areas within the exit enclosure shall be provided with a solid and continuous perimeter demarcation marking stripe on the floor or on the walls or a combination of both. The marking stripe shall also meet all of the following requirements:

- (1) The marking stripe shall have a minimum horizontal width of 1 in. (25 mm) and a maximum width of 2 in. (51 mm), with interruptions not exceeding 4 in. (100 mm).
  - (2) The minimum marking stripe width of 1 in. (25 mm) shall not apply to outlining stripes listed in accordance with ANSI/UL 1994, *Standard for Luminous Egress Path Marking Systems*.
  - (3) The dimensions and placement of the perimeter demarcation marking stripe shall be uniform and consistent throughout the exit enclosure.
  - (4) Surface-applied marking stripes using adhesive-backed tapes shall not be used.
- (A)** Perimeter floor demarcation lines shall comply with all of the following:
- (1) They shall be placed within 4 in. (100 mm) of the wall and extend to within 2 in. (51 mm) of the markings on the leading edge of landings.
  - (2) They shall continue across the floor in front of all doors.
  - (3) They shall not extend in front of exit doors leading out of an exit enclosure and through which occupants must travel to complete the egress path.
- (B)** Perimeter wall demarcation lines shall comply with all of the following:
- (1) They shall be placed on the wall with the bottom edge of the stripe not more than 4 in. (100 mm) above the finished floor.

- (2) At the top or bottom of the stairs, they shall drop vertically to the floor within 2 in. (51 mm) of the step or landing edge.
- (3) They shall transition vertically to the floor and then extend across the floor where a line on the floor is the only practical method of outlining the path.
- (4) Where the wall line is broken by a door, they shall continue across the face of the door or transition to the floor and extend across the floor in front of such door.
- (5) They shall not extend in front of doors leading out of an exit enclosure and through which occupants must travel to complete the egress path.
- (6) Where a wall-mounted demarcation line transitions to a floor-mounted demarcation line, or vice versa, the wall-mounted demarcation line shall drop vertically to the floor to meet a complementary extension of the floor-mounted demarcation line, thus forming a continuous marking.

**7.2.2.5.5.5\* Obstacles.** Obstacles that are in the exit enclosure at or below 6 ft 6 in. (1980 mm) in height, and that project more than 4 in. (100 mm) into the egress path, shall be identified with markings not less than 1 in. (25 mm) in horizontal width comprised of a pattern of alternating equal bands of luminescent material and black; and with the alternating bands not more than 2 in. (51 mm) in horizontal width and angled at 45 degrees.

**A.7.2.2.5.5.5** Examples of obstacles addressed by **7.2.2.5.5.5** are standpipes, hose cabinets, and wall projections.

**7.2.2.5.5.6 Doors Serving Exit Enclosure.** All doors serving the exit enclosure that swing out from the enclosure in the direction of egress travel shall be provided with a marking stripe on the top and sides of the door(s) frame(s). The marking stripe shall also meet all of the following requirements:

- (1) The marking stripe shall have a minimum horizontal width of 1 in. (25 mm) and a maximum width of 2 in. (51 mm).
- (2) Gaps shall be permitted in the continuity of door frame markings where a line is fitted into a corner or bend, but shall be as small as practicable, and in no case shall gaps be greater than 1 in. (25 mm).
- (3) Where the door molding does not provide enough flat surface on which to locate the marking stripe, the marking stripe shall be located on the wall surrounding the frame.
- (4) The dimensions and placement of the marking stripe shall be uniform and consistent on all doors in the exit enclosure.

**7.2.2.5.5.7 Door Hardware Marking.**

**(A)** The door hardware for the doors serving the exit enclosure that swing out from the enclosure in the direction of egress travel shall be provided with a marking stripe.

**(B)** The marking stripe shall also meet the following requirements:

- (1)\* The door hardware necessary to release the latch shall be outlined with an approved marking stripe having a minimum width of 1 in. (25 mm).

**A.7.2.2.5.5.7(B)(1)** The marking stripe for door hardware should be of sufficient size to adequately mark the door hardware. This marking could be located behind, immediately adjacent to, or on the door handle or escutcheon.

- (2) Where panic hardware is installed, both of the following criteria shall be met:
  - (a) The marking stripe shall have a minimum width of 1 in. (25 mm) and be applied to the entire length of the actuating bar or touch pad.
  - (b) The placement of the marking stripe shall not interfere with viewing of any instructions on the actuating bar or touch pad.

**7.2.2.5.5.8 Emergency Exit Symbol.** An emergency exit symbol with a luminescent background shall be applied on all doors serving the exit enclosure that swing out from the enclosure in the direction of egress travel. The emergency exit symbol shall also meet both of the following requirements:

- (1) The emergency exit symbol shall meet the requirements of NFPA 170, *Standard for Fire Safety and Emergency Symbols*.
- (2) The emergency exit symbol applied on the door shall be a minimum of 4 in. (100 mm) in height and shall be applied on the door, centered horizontally, with the top of the symbol not higher than 18 in. (455 mm) above the finished floor.

**7.2.2.5.5.9 Uniformity.** Placement and dimensions of the marking stripes shall be consistent and uniform throughout the same exit enclosure.

**7.2.2.5.5.10 Materials.** Exit stair path markings shall be made of any material, including paint, provided that an electrical charge is not required to maintain the required luminescence. Such materials shall include, but shall not be limited to, self-luminous materials and photoluminescent materials. Materials shall comply with one of the following:

- (1) ASTM E 2072, *Standard Specification for Photoluminescent (Phosphorescent) Safety Markings*, with the following exceptions:
  - (a) The charging source shall be 1 ft-candle (10.8 lux) of fluorescent illumination for 60 minutes.
  - (b) The minimum luminance shall be 5 millicandelas/m<sup>2</sup> after 90 minutes.
- (2) ANSI/UL 1994, *Standard for Luminous Egress Path Marking Systems*

**7.2.2.5.5.11 Exit Stair Illumination.** Exit enclosures where photoluminescent materials are installed shall comply with all of the following:

- (1) The exit enclosure shall be continuously illuminated for at least 60 minutes prior to periods when the building is occupied.
- (2) The illumination shall remain on when the building is occupied.

(3) Lighting control devices provided for illumination within the exit enclosure shall meet all of the following requirements:

- (a) Lighting control devices that automatically turn exit enclosure lighting on and off, based on occupancy, shall be permitted, provided that they turn on illumination for charging photoluminescent materials for at least 60 minutes prior to periods when the building is occupied.
- (b) Lighting used to charge photoluminescent materials shall not be controlled by motion sensors.
- (c) Lighting control devices that dim the lighting levels within the exit enclosure shall not be installed unless they provide a minimum of 1 ft-candle (10.8 lux) of illumination within the exit enclosure measured at the walking surface.

The provisions of 7.2.2.5.5 on exit stair path markings were assembled from a variety of sources, including General Services Administration standards and the New York City requirements applicable to high-rise buildings. Detailed criteria are presented as a set of requirements that run from the base paragraph of 7.2.2.5.5 through 7.2.2.5.5.11. The provisions are formatted so as to provide the “how-to” details regarding where exit stair path markings are required by some other section of the *Code*, typically the occupancy chapters, although there is potential that exit stair path marking might be mandated in future editions by other provisions of the core chapters. For example, exit path markings might be used to enhance the high-rise building protection provisions detailed in Section 11.8.

No provision of the 2015 edition of the *Code* mandates the use of 7.2.2.5.5. Users of the *Code* should view the requirements of 7.2.2.5.5 as guidance that should be followed where exit stair path markings are provided voluntarily, as such markings, if not properly installed, might have the effect of making the stair less usable than a stair with no markings. The National Research Council Canada’s Institute for Research in Construction has actively evaluated photoluminescent markings in stairwells. Some of its work is summarized in the following research reports:

1. *Evaluation of the Effectiveness of Different Photoluminescent Stairwell Installations for the Evacuation of Office Building Occupants*<sup>13</sup>
2. *Evaluation and Comparison of Different Installations of Photoluminescent Marking in Stairwells of a Highrise Building*<sup>14</sup>

The criteria of 7.2.2.5.5 help to prevent the marking stripes from providing misleading cues to stair users that might make use of the stair less safe or more confusing than if the marking stripes were not installed. For example, 7.2.2.5.5.1(B)(2) limits the marking stripe that extends across the full width of the leading edge of the stair tread to a maximum width of 2 in. (51 mm) to ensure that all but the leading edge of the tread is left unmarked, so a person using the stair in the downward direction sees individual tread edges, and not one continuously marked sloping

Exhibit 7.115

Stair enclosure with photoluminescent path markings in normal illumination. (Photo courtesy of Jake Pauls)

plane. The undesired continuously marked sloping plane would create a ramp effect, with no indication of the location of the leading edge of each tread.

The provisions of 7.2.2.5.5 and those of Section 7.10 for photoluminescent (PL) exit signs are not fully correlated. For example, 7.2.2.5.5.11 requires that, where exit stair path marking is installed using PL materials, the materials must be continuously illuminated for at least 60 minutes prior to periods when the building is occupied. Before a photoluminescent material can release electromagnetic radiation in the form of visible light, it must store incident electromagnetic radiation that typically reaches the material in the form of visible light. The illumination requirement of 7.2.2.5.5.11 is inconsistent with the philosophy applied to PL exit signs in Section 7.10. Photoluminescent exit signs are required by 7.10.7.1 to be listed in accordance with ANSI/UL 924, *Standard for Emergency Lighting and Power Equipment*.<sup>15</sup> ANSI/UL 924 requires that the sign be marked with a caution note that external illumination is required at all times that the building is occupied, but does not require any mention of providing a charging illumination prior to building occupancy. Further, 7.10.7.2 specifies that the face of the PL sign must be continuously illuminated while the building is occupied, so as to charge the PL material, but says nothing about providing illumination prior to building occupancy.

Exhibit 7.115 shows an exit stair enclosure equipped with photoluminescent path markings with normal illumination. Exhibit 7.116 shows the same exit stair enclosure, but in a darkened state with the photoluminescent materials glowing.

### 7.2.2.6 Special Provisions for Outside Stairs.

**7.2.2.6.1 Access.** Where approved by the authority having jurisdiction, outside stairs shall be permitted to lead to roofs of other sections of a building or an adjoining building where the construction is fire resistive and there is a continuous and safe means of egress from the roof. (See also 7.7.6.)

Exhibit 7.116

Darkened stair enclosure with photoluminescent path markings. (Photo courtesy of Jake Pauls)

**7.2.2.6.2\* Visual Protection.** Outside stairs shall be arranged to avoid any impediments to their use by persons having a fear of high places. Outside stairs more than 36 ft (11 m) above the finished ground level, other than previously approved existing stairs, shall be provided with an opaque visual obstruction not less than 48 in. (1220 mm) in height.

**A.7.2.2.6.2** The guards that are required by 7.1.8 and detailed in 7.2.2.4.5 will usually meet this requirement where the stair is not more than 36 ft (11 m) above the finished ground level. Special architectural treatment, including application of such devices as metal or masonry screens and grilles, will usually be necessary to comply with the intent of this requirement for stairs over 36 ft (11 m) above the finished ground level.

Outside stairs frequently have an open side. Required rails and guards help to prevent falls but do nothing to shield the user's view of the vertical drop. The fear of using such stairs, and the resultant decrease in the effectiveness of the stair as an egress component, justify the requirement for an opaque visual obstruction. The opaque visual barrier, required for stairs more than 36 ft (11 m) above the finished ground level, is required to be a minimum of 48 in. (1220 mm) high — a height that exceeds the 42 in. (1065 mm) criterion for guards at the open edge. Exhibit 7.117 shows an outside stair with opaque visual barriers at the sides of the stair treads and landings.

### 7.2.2.6.3 Separation and Protection of Outside Stairs.

**7.2.2.6.3.1\*** Outside stairs shall be separated from the interior of the building by construction with the fire resistance rating required for enclosed stairs with fixed or self-closing opening protectives, except as follows:

- (1) Outside stairs serving an exterior exit access balcony that has two remote outside stairways or ramps shall be permitted to be unprotected.

**Exhibit 7.117**

Outside stair with opaque visual barriers. (Photo courtesy of Jake Pauls)

- (2) Outside stairs serving two or fewer adjacent stories, including the story where the exit discharges, shall be permitted to be unprotected where there is a remotely located second exit.
- (3) In existing buildings, existing outside stairs serving three or fewer adjacent stories, including the story where the exit discharges, shall be permitted to be unprotected where there is a remotely located second exit.
- (4) The fire resistance rating of a separation extending 10 ft (3050 mm) from the stairs shall not be required to exceed 1 hour where openings have a minimum  $\frac{3}{4}$ -hour fire protection rating.
- (5) Outside stairs in existing buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with **Section 9.7** shall be permitted to be unprotected.

**A.7.2.2.6.3.1** Where outside stairs are not required to be separated from interior portions of the building in accordance with **7.2.2.6.3.1(1)** through (5), such stairs are considered exits and not exit access.

**7.2.2.6.3.2** Wall construction required by **7.2.2.6.3.1** shall extend as follows:

- (1) Vertically from the finished ground level to a point 10 ft (3050 mm) above the topmost landing of the stairs or to the roofline, whichever is lower
- (2) Horizontally for not less than 10 ft (3050 mm)

**7.2.2.6.3.3** Roof construction required by **7.2.2.6.3.1** shall meet both of the following criteria:

- (1) It shall provide protection beneath the stairs.
- (2) It shall extend horizontally to each side of the stair for not less than 10 ft (3050 mm).

The provisions of **7.2.2.6.3** address the proximity of outside stairs to openings in the building wall through which fire emerging from the building could render the stairs useless as a means of egress. Protection against such an occurrence is achieved by one of the following:

1. Protection from openings by separation distances
2. Protection of openings by fire-rated door assemblies and fire-rated windows
3. Compliance with one of the exemptions detailed in **7.2.2.6.3.1(1)** through (3) or **7.2.2.6.3.1(5)**

The arrangement typical of old fire escapes, where a window access is positioned immediately below a fire escape landing, creates the potential for fire exposure of the fire escape and is not permitted for outside stairs. The separation and protection provisions in **7.2.2.6.3** for outside stairs are illustrated in **Exhibit 7.118**, **Exhibit 7.119**, and **Exhibit 7.120**.

In **Exhibit 7.118**, if openings are within 10 ft (3050 mm) of the outside stairs, they must be protected (see **7.2.2.6.3.2**). However, the fire resistance ratings in the 10 ft (3050 mm) extension need not exceed 1 hour, and the fire protection rating for the opening need not exceed  $\frac{3}{4}$  hour.

In **Exhibit 7.119**, the fire resistance rating for the walls within the outer colored area that represents a 10 ft (3050 mm) extension is a minimum of 1 hour. The fire resistance rating required for the walls within the inner colored area is based on the number of stories served by the outside stair — the same as for interior stairs — as addressed in **7.1.3.2.1**.

In **Exhibit 7.120**, the exemption permitted by **7.2.2.6.3.1(1)** is illustrated in Part (a) of **Exhibit 7.120**. The exemption permitted by **7.2.2.6.3.1(2)**, which is restricted to stairways serving not more than two adjacent stories, is illustrated in Part (b) of **Exhibit 7.120**. Part (b) also illustrates the exemption permitted by **7.2.2.6.3.1(3)**, though that exemption permits stairways to serve up to three adjacent stories and is restricted to use in existing buildings. Each of the three outside stairs shown in Part (a) and Part (b) of **Exhibit 7.120** is an exit, and the *Code* user is reminded of this by the text of **A.7.2.2.6.3.1**. See the commentary following **7.6.2** and **7.6.4** relative to the end point for travel distance measurement on unenclosed stairs that are exits.

**7.2.2.6.4 Protection of Openings.** All openings below an outside stair shall be protected with an assembly having a minimum  $\frac{3}{4}$ -hour fire protection rating as follows:

- (1) Where located in an enclosed court (see **3.3.50.1**), the smallest dimension of which does not exceed one-third its height
- (2) Where located in an alcove having a width that does not exceed one-third its height and a depth that does not exceed one-fourth its height

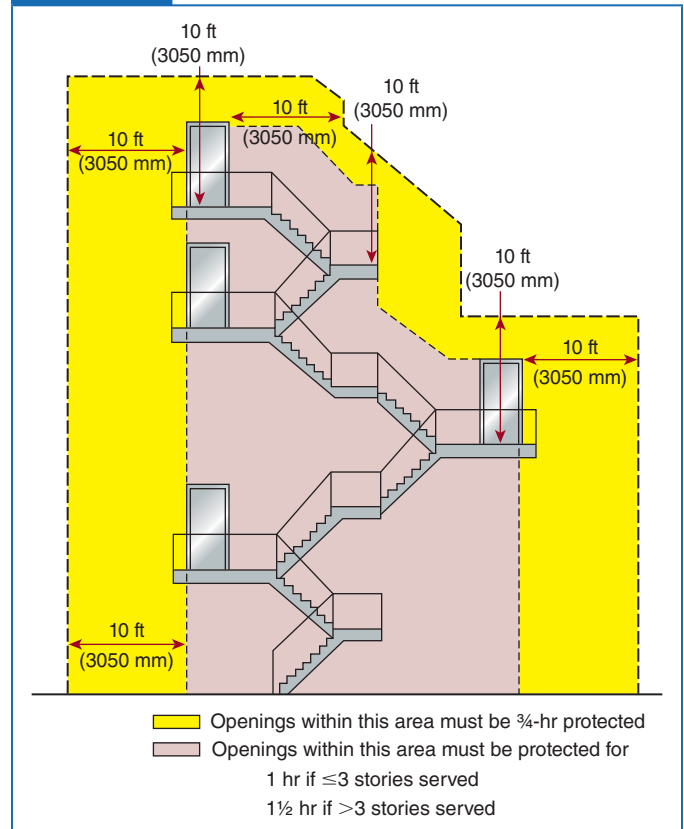

**Exhibit 7.118**

Protection of openings for outside stairs — Example 1.

**Exhibit 7.119**

Protection of openings for outside stairs — Example 2.

Exhibit 7.121 illustrates the provisions of 7.2.2.6.4(2). All openings along the alcove walls and located at an elevation less than that of the outside stairs are required to be protected if  $D$  (depth) is less than or equal to one-fourth of  $H$  (height) and  $W$  (width) is less than or equal to one-third of  $H$ .

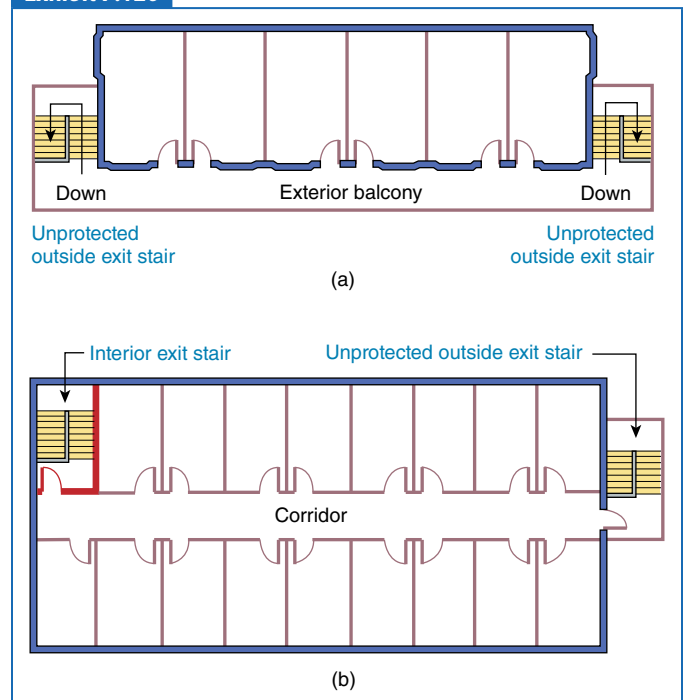

**Example**

- $H = 60 \text{ ft (18.3 m)}$
- $D = 15 \text{ ft (4570 mm)}$
- $W = 20 \text{ ft (6100 mm)}$

Therefore, in this example, all openings along the alcove walls and located at an elevation less than the outside stairs must be protected by opening protectives (e.g., fire windows) with a minimum fire protection rating of 3/4 hour.

Note that the alcove depicted in Exhibit 7.121 is considered an alcove because it is open on one side. Paragraph 7.2.2.6.4(1) addresses an enclosed court, as defined in 3.3.50.1. It requires that if either  $D$  or  $W$  is one-third or less of  $H$ , all openings along the enclosed court walls and located at an elevation less than the outside stairs must be protected by opening protectives (e.g., fire windows) with a minimum fire protection rating of 3/4 hour.

**Exhibit 7.120**

Protection of openings for outside stairs — Example 3 and Example 4.

Exhibit 7.121

Basis for required protection of openings below open, outside stairs discharging to an alcove.

**7.2.2.6.5\* Water Accumulation.** Outside stairs and landings, other than existing outside stairs and landings, shall be designed to minimize water accumulation on their surfaces.

Exhibit 7.122 shows water accumulation on an outside stair landing.

**A.7.2.2.6.5** See A.7.2.2.3.4.

**7.2.2.6.6 Openness.** Outside stairs, other than existing outside stairs, shall be not less than 50 percent open on one side. Outside stairs shall be arranged to restrict the accumulation of smoke.

Paragraph 7.2.2.6.6 does not specify that the longer side of the new outside stair must be the side that is arranged to be at least

Exhibit 7.122

Water accumulation on an outside stair landing. (Photo courtesy of Jake Pauls)

50 percent open. The shorter side of the stair can be arranged to be at least 50 percent open, if such arrangement complies with the performance-based requirement imposed by the second sentence of 7.2.2.6.6.

### 7.2.3 Smokeproof Enclosures.

**7.2.3.1 General.** Where smokeproof enclosures are required in other sections of this Code, they shall comply with 7.2.3, unless they are approved existing smokeproof enclosures.

A smokeproof enclosure has traditionally taken the form of an exit stair enclosure provided with additional features that limit the infiltration of heat, smoke, and fire gases from a fire in any part of a building. A pressurized stair enclosure is an example of this form of smokeproof enclosure. Smokeproof enclosures, other than exit stair enclosures, include pressurized elevator hoistway shafts. A smokeproof enclosure improves protection against the products of combustion entering the enclosure. The Code requires the use of smokeproof enclosures in 31.2.11.1 for existing, nonsprinklered, high-rise apartment building stairs. The provisions for smokeproof enclosures also are mandated for hoistway shaft systems for elevators providing access from an area of refuge to a public way in accordance with 7.2.12.2.4(3).

**7.2.3.2 Performance Design.** An appropriate design method shall be used to provide a system that meets the definition of *smokeproof enclosure* (see 3.3.257). The smokeproof enclosure shall be permitted to be created by using natural ventilation, by using mechanical ventilation incorporating a vestibule, or by pressurizing the stair enclosure.

Paragraph 7.2.3.2 requires that smokeproof enclosures meet the performance criterion contained in the definition of *smokeproof enclosure* in 3.3.257. Paragraph 7.2.3.2 also specifies three different means of creating smokeproof enclosures, as follows:

1. By use of natural ventilation as detailed in 7.2.3.7
2. By mechanical ventilation in accordance with 7.2.3.8
3. By pressurizing the enclosure as outlined in 7.2.3.9

However, the Code does not restrict the design to one of the three methods detailed in the previous paragraph if the design meets the performance requirements and is acceptable to the authority having jurisdiction. This alternative is especially important for existing smokeproof enclosures, because they often do not meet all the prescriptive-based specifications that follow.

Exhibit 7.123 illustrates four variations of exit stair enclosure smokeproof enclosures that meet the specific Code criteria contained in 7.2.3.4 through 7.2.3.8. Plan A utilizes an open-air vestibule. Plan B shows entrance to the smokeproof enclosure by way of an outside balcony. Plan C provides a stair enclosure entrance common to two building areas. In Plan D, smoke and gases entering the vestibule are exhausted by mechanical ventilation. In each case, a double entrance to the stair enclosure with at least one side open or vented is characteristic of the type of construction. Pressurization of the stair enclosure in the event of fire

Exhibit 7.123

Four variations of smokeproof enclosures.

provides an attractive alternative and is a means of eliminating the need for an entrance vestibule.

### 7.2.3.3 Enclosure.

**7.2.3.3.1** A smokeproof enclosure shall be continuously enclosed by barriers having a 2-hour fire resistance rating from the highest point to the level of exit discharge, except as otherwise permitted in 7.2.3.3.3.

**7.2.3.3.2** Where a vestibule is used, it shall be within the 2-hour-rated enclosure and shall be considered part of the smokeproof enclosure.

**7.2.3.3.3** A smokeproof enclosure comprised of an enclosed stair and serving floors below the level of exit discharge shall not be required to comply with 7.2.3.3.1 where the portion of the stairway below is separated from the stairway enclosure at the level of exit discharge by barriers with a 1-hour fire resistance rating.

**7.2.3.4 Vestibule.** Where a vestibule is provided, the door opening into the vestibule shall be protected with an approved fire door assembly having a minimum 1 1/2-hour fire protection rating, and the fire door assembly from the vestibule to the smokeproof enclosure shall have a minimum 20-minute fire protection rating. Door leaves shall be designed to minimize air leakage and shall be self-closing or shall be automatic-closing by actuation of a smoke detector within 10 ft (3050 mm) of the vestibule door opening. New door assemblies shall be installed in accordance with NFPA 105, *Standard for Smoke Door Assemblies and Other Opening Protectives*.

The provisions of 7.2.3.3 require that the smokeproof enclosure and all of its components be within the required 2-hour fire resistance-rated enclosure, with openings therein protected by a door assembly having a 1 1/2-hour fire protection rating. Such an arrangement protects the smokeproof enclosure from the direct attack of fire. However, per 7.2.3.4, the assembly from the vestibule (within the 2-hour-rated enclosure) into the actual stairway requires only a 20-minute fire protection rating, because the purpose of this door assembly is to minimize air or smoke leakage. Such door assemblies, other than in existing installations, are required to be smoke leakage-rated door assemblies installed in accordance with NFPA 105, *Standard for Smoke Door Assemblies and Other Opening Protectives*. The AHJ is to qualitatively evaluate existing door assemblies with respect to their ability to restrict smoke movement through the gaps between the door leaf and the door frame.

### 7.2.3.5 Discharge.

**7.2.3.5.1** Every smokeproof enclosure shall discharge into a public way, into a yard or court having direct access to a public way, or into an exit passageway. Such exit passageways shall be without openings, other than the entrance to the smokeproof enclosure and the door opening to the outside yard, court, or public way. The exit passageway shall be separated from the remainder of the building by a 2-hour fire resistance rating.

**7.2.3.5.2** The smokeproof enclosure shall be permitted to discharge through interior building areas, provided that all of the following criteria are met:

- (1) The building shall be protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7.
- (2) The discharge from the smokeproof enclosure shall lead to a free and unobstructed way to an exterior exit, and such way shall be readily visible and identifiable from the point of discharge from the smokeproof enclosure.
- (3) Not more than 50 percent of the required number and capacity of exits comprised of smokeproof enclosures shall discharge through interior building areas in accordance with 7.7.2.

Code editions prior to 2012 prohibited smokeproof enclosures from discharging through interior building levels, including the

level of exit discharge. The provision of 7.2.3.5.2 is now similar to that of 7.7.2, which permits up to 50 percent of the exit stair enclosures to discharge through interior building areas.

**7.2.3.6 Access.** For smokeproof enclosures other than those consisting of a pressurized enclosure complying with 7.2.3.9, access to the smokeproof enclosure shall be by way of a vestibule or by way of an exterior balcony.

**7.2.3.7 Natural Ventilation.** Smokeproof enclosures using natural ventilation shall comply with 7.2.3.3 and all of the following:

- (1) Where access to the enclosure is by means of an open exterior balcony, the door assembly to the enclosure shall have a minimum 1½-hour fire protection rating and shall be self-closing or shall be automatic-closing by actuation of a smoke detector.
- (2) Openings adjacent to the exterior balcony specified in 7.2.3.7(1) shall be protected in accordance with 7.2.2.6.4.
- (3) Every vestibule shall have a net area of not less than 16 ft<sup>2</sup> (1.5 m<sup>2</sup>) of opening in an exterior wall facing an exterior court, yard, or public space not less than 20 ft (6100 mm) in width.
- (4) Every vestibule shall have a minimum dimension of not less than the required width of the corridor leading to it and a dimension of not less than 6 ft (1830 mm) in the direction of travel.

**7.2.3.8 Mechanical Ventilation.** Smokeproof enclosures using mechanical ventilation shall comply with 7.2.3.3 and the requirements of 7.2.3.8.1 through 7.2.3.8.4.

**7.2.3.8.1** Vestibules shall have a dimension of not less than 44 in. (1120 mm) in width and not less than 6 ft (1830 mm) in the direction of travel.

**7.2.3.8.2** The vestibule shall be provided with not less than one air change per minute, and the exhaust shall be 150 percent of the supply. Supply air shall enter and exhaust air shall discharge from the vestibule through separate tightly constructed ducts used only for such purposes. Supply air shall enter the vestibule within 6 in. (150 mm) of the floor level. The top of the exhaust register shall be located not more than 6 in. (150 mm) below the top of the trap and shall be entirely within the smoke trap area. Door leaves, when in the open position, shall not obstruct duct openings. Controlling dampers shall be permitted in duct openings if needed to meet the design requirements.

**7.2.3.8.3** To serve as a smoke and heat trap and to provide an upward-moving air column, the vestibule ceiling shall be not less than 20 in. (510 mm) higher than the door opening into the vestibule. The height shall be permitted to be decreased where justified by engineering design and field testing.

**7.2.3.8.4** The stair shall be provided with a dampered relief opening at the top and supplied mechanically with sufficient air to discharge at least 2500 ft<sup>3</sup>/min (70.8 m<sup>3</sup>/min) through the relief

opening while maintaining a positive pressure of not less than 0.10 in. water column (25 N/m<sup>2</sup>) in the stair, relative to the vestibule with all door leaves closed.

Exhibit 7.124 illustrates an elevation view of a smokeproof enclosure vestibule that uses mechanical ventilation. The minimum height of the door opening, specified as 6 ft 8 in. (2030 mm) in Exhibit 7.124, is mandated by 7.1.5.1, not by 7.2.3.8.

*Mechanical ventilation form of smokeproof enclosure.*

### 7.2.3.9 Enclosure Pressurization.

**7.2.3.9.1\*** Smokeproof enclosures using pressurization shall use an approved engineered system with a design pressure difference across the barrier of not less than 0.05 in. water column (12.5 N/m<sup>2</sup>) in sprinklered buildings, or 0.10 in. water column (25 N/m<sup>2</sup>) in nonsprinklered buildings, and shall be capable of maintaining these pressure differences under likely conditions of stack effect or wind. The pressure difference across door openings shall not exceed that which allows the door leaves to begin to be opened by a force of 30 lbf (133 N) in accordance with 7.2.1.4.5.

**A.7.2.3.9.1** The design pressure differences required by 7.2.3.9.1 are based on specific gas temperatures and ceiling heights. The system is required to be approved, because anticipated conditions might be different from those on which the design pressure differences were calculated and, thus, different design pressure differences might be needed. For additional information on necessary minimum design pressure differences, including calculational techniques, or maximum pressure differences across doors to ensure reasonable operating forces, see NFPA 92, *Standard for Smoke Control Systems*.

Pressurized stairs are permitted to be used as smokeproof enclosures in either nonsprinklered or sprinklered buildings. However, the design pressure difference across the barrier in a nonsprin-

klered building is required to be twice that required in a sprinklered building.

**7.2.3.9.2** Equipment and ductwork for pressurization shall be located in accordance with one of the following specifications:

- (1) Exterior to the building and directly connected to the enclosure by ductwork enclosed in noncombustible construction
- (2) Within the enclosure with intake and exhaust air vented directly to the outside or through ductwork enclosed by a 2-hour fire-resistive rating
- (3) Within the building under the following conditions:
  - (a) Where the equipment and ductwork are separated from the remainder of the building, including other mechanical equipment, by a 2-hour fire-resistive rating
  - (b) Where the building, including the enclosure, is protected throughout by an approved, supervised automatic sprinkler system installed in accordance with [Section 9.7](#), and the equipment and ductwork are separated from the remainder of the building, including other mechanical equipment, by not less than a 1-hour fire-resistive rating

**7.2.3.9.3** In all cases specified by [7.2.3.9.2](#)(1) through (3), openings into the required fire resistance-rated construction shall be limited to those needed for maintenance and operation and shall be protected by self-closing fire protection-rated devices in accordance with [8.3.4](#).

[Exhibit 7.125](#), [Exhibit 7.126](#), and [Exhibit 7.127](#) illustrate arrangements that comply with [7.2.3.9.2](#). In [Exhibit 7.127](#), the required fire-rated separation is permitted to be reduced from 2 hours to 1 hour where the building, including the stairway enclosure, is protected throughout by an approved, supervised automatic sprinkler system.

### 7.2.3.10 Activation of Mechanical Ventilation and Pressurized Enclosure Systems.

**7.2.3.10.1** For both mechanical ventilation and pressurized enclosure systems, the activation of the systems shall be initiated by a smoke detector installed in an approved location within 10 ft (3050 mm) of each entrance to the smokeproof enclosure.

**Exhibit 7.125**

Mechanical equipment and ductwork complying with [7.2.3.9.2](#)(1).

**Exhibit 7.126**

Mechanical equipment and ductwork complying with [7.2.3.9.2](#)(2).

**Exhibit 7.127**

Mechanical equipment and ductwork complying with [7.2.3.9.2](#)(3).

[Paragraph 7.2.3.10.1](#) requires that a smoke detector for activation of the ventilation system be positioned at each entrance to the smokeproof enclosure. In editions prior to 2009, the requirement was for a smoke detector to be positioned at *the* (i.e., *an*) entrance. Each entrance must be monitored for smoke.

**7.2.3.10.2** The required mechanical system shall operate upon the activation of the smoke detectors specified in [7.2.3.10.1](#) and by manual controls accessible to the fire department. The required system also shall be initiated by the following, if provided:

- (1) Waterflow signal from a complete automatic sprinkler system
- (2) General evacuation alarm signal (*see* [9.6.3.6](#))

**7.2.3.11 Door Leaf Closers.** The activation of an automatic-closing device on any door leaf in the smokeproof enclosure shall activate all other automatic-closing devices on door leaves in the smokeproof enclosure.

**7.2.3.12 Emergency Power Supply System (EPSS).** Power shall be provided as follows:

- (1) A Type 60, Class 2, Level 2 EPSS for new mechanical ventilation equipment shall be provided in accordance with NFPA 110, *Standard for Emergency and Standby Power Systems*.

- (2) A previously approved existing standby power generator installation with a fuel supply adequate to operate the equipment for 2 hours shall be permitted in lieu of 7.2.3.12(1).
- (3) The generator shall be located in a room separated from the remainder of the building by fire barriers having a minimum 1-hour fire resistance rating.

A Type 60 emergency power supply system (EPSS) must restore power within 60 seconds of the failure of the primary power source. A Class 2 EPSS must be capable of operating at its rated load without being refueled for a minimum of 2 hours. Level 2 performance is specified based on the technical committee's judgment that failure of the EPSS is less critical to human life and safety.

For an example where Level 1 performance, for EPSS critical to human life and safety, is specified in the Code, see 7.9.2.2, which is related to new emergency power systems for emergency lighting. See also NFPA 110, *Standard for Emergency and Standby Power Systems*.<sup>16</sup>

**7.2.3.13 Testing.** Before the mechanical equipment is accepted by the authority having jurisdiction, it shall be tested to confirm that it is operating in compliance with the requirements of 7.2.3. All operating parts of the system shall be tested semiannually by approved personnel, and a log shall be kept of the results.

## 7.2.4 Horizontal Exits.

### 7.2.4.1 General.

**7.2.4.1.1** Where horizontal exits are used in the means of egress, they shall conform to the general requirements of Section 7.1 and the special requirements of 7.2.4.

**7.2.4.1.2\*** Horizontal exits shall be permitted to be substituted for other exits where the total egress capacity and the total number of the other exits (stairs, ramps, door openings leading outside the building) is not less than half that required for the entire area of the building or connected buildings, and provided that none of the other exits is a horizontal exit, unless otherwise permitted by 7.2.4.1.3.

**A.7.2.4.1.2** An example of one way to provide the required egress capacity from the upper floor of a department store building measuring 350 ft × 200 ft (107 m × 61 m), with an occupant load of 1166 per floor, would be to furnish eight 44 in. (1120 mm) stairs. [See Figure A.7.2.4.1.2(a).]

The building is assumed to be divided into two sections by a fire barrier meeting the requirements for a horizontal exit, one 130 ft × 200 ft (40 m × 61 m), and the other 220 ft × 200 ft (67 m × 61 m), with two pairs of 46 in. (1170 mm) double egress doors, with each door providing 44 in. (1120 mm) of clear egress width [see Figure A.7.2.4.1.2(b)]. The smaller section, considered separately, will require the equivalent of three 44 in. (1120 mm) exit stairs, and the larger section will require five such exits. The horizontal exits will serve as one of the three exits required for the smaller section and two of the five exits

**Figure A.7.2.4.1.2(a)** Eight Exits, Required to Provide Necessary Egress Capacity, with None via Horizontal Exit.

**Figure A.7.2.4.1.2(b)** Number of Stairs Reduced by Three Through Use of Two Horizontal Exits; Egress Capacity Not Reduced.

required for the larger section. Therefore, only two 44 in. (1120 mm) exit stairs from the smaller section and three 44 in. (1120 mm) exit stairs from the larger section will be required if the exits can be arranged to meet the requirements for the 150 ft (46 m) travel distance permitted from any point in a nonsprinklered building. Thus, the total number of exit stairs required for the building will be five, as compared to eight if no horizontal exit had been provided.

Another option would be the use of two 56 in. (1420 mm) exit stairs from the larger section, which would reduce the total number of stairways required from the floor to four [see Figure A.7.2.4.1.2(c)]. However, if the building were further subdivided by a second fire wall meeting the requirements for a horizontal exit, no further reduction in stairways would be permitted in order to comply with the requirement that horizontal exits provide a maximum of one-half of egress capacity.

It is not the intent of 7.2.4.1.2 to limit the number of doors in the fire barrier forming the horizontal exit. Where doors other than those serving as horizontal exits are provided, such doors are permitted to be considered as part of the exit access and not as exits.

**Figure A.7.2.4.1.2(c)** Number of Stairs Further Reduced by Widening Stairs in Larger Compartment, But Not to Less than One-Half the Required Number and Capacity of Exits from That Compartment.

**7.2.4.1.3** The requirement of 7.2.4.1.2 shall not apply to the following:

- (1) Health care occupancies as otherwise provided in **Chapters 18** and **19**
- (2) Detention and correctional occupancies as otherwise provided in **Chapters 22** and **23**

A horizontal exit is a combination of fire-rated walls with fire-rated door assemblies providing passage from one building area into another building area; each area is a fire compartment independent of the other compartment. A horizontal exit, however, need not be confined to one building. It can be used as a bridge from one building to another. Just as with other types of exits, the horizontal exit has components consisting of door assemblies and enclosure walls. Structural features, such as bridges and balconies, are sometimes used in the passage from one area to the other. Horizontal exits typically do not include stairs or ramps, because they are usually located on the same level as the area from which escape is desired. See the definition of *horizontal exit* in 3.3.83.1, which includes the words “passage through . . . a fire barrier to an area of refuge on approximately the same level . . .”

Horizontal exits are internal exits that might be located some distance from a door assembly leading to the outside at the level of exit discharge or to an exit stair enclosure on a floor above the level of exit discharge, so the *Code* permits them to provide not more than one-half the required number of exits and not more than one-half of the egress capacity of the floor or floors that they connect. However, in health care occupancies and detention and correctional occupancies, special exemptions apply to permit additional reliance on horizontal exits as part of a defend-in-place protection strategy, as noted in 7.2.4.1.3.

Before any space can be used as an occupant accumulation area on either side of a horizontal exit, it must satisfy certain criteria. Such a space, although separated with 2-hour fire barriers

(see 7.2.4.3 for details on the fire barrier), cannot be used as a horizontal exit unless there is at least one standard type of exit (not an additional horizontal exit) leading from the space to ensure occupants are not trapped within a fire compartment with no other way out. Additionally, the compartment must be large enough to provide occupant accumulation space for the occupants of both the fire compartment containing the fire and the non-fire compartment, allowing 3 ft<sup>2</sup> (0.28 m<sup>2</sup>) of floor space per person. The accumulation space permits occupants of the refuge compartment to wait in safety until the standard type of exits from the compartment (which are not required to be sized to accommodate the total accumulated number of occupants) can accommodate everyone.

The required accumulation space per person is increased in health care occupancies, because occupants might be on gurneys and stretchers; the accumulation space is also increased in detention and correctional occupancies, where the residents are normally held in the non-fire compartment for a considerable time, rather than being released to the outside, because crowded conditions might lead to behavioral problems among the residents. The nature of a horizontal exit is such that it provides psychological comfort. Being held in an area or building that is away from the fire reassures occupants and prevents disorderly movement.

**Exhibit 7.128** illustrates how to apply the requirement of 7.2.4.1.2 when substituting horizontal exits for other exits. Note that the door assemblies in the horizontal exits (yellow highlighted) substitute for exit stair enclosures. For example, the two horizontal exit door leaves that swing into Compartment A are permitted to be substituted for the exit stair enclosures in Compartment B that are designated as numbers 1 and 3 [see 7.2.4.3.8(1)]. The two horizontal exit door leaves that swing into

*Example of substituting horizontal exits for other exits.*

Compartment B might provide sufficient egress width to be substituted for two of the exit stair enclosures in Compartment A, but to do so would violate the limitation of 7.2.4.1.2 that horizontal exits not comprise more than one-half of the required number of exits for a compartment, so only one exit stair enclosure, designated as number 2, is rendered unnecessary in Compartment A via the creation of the horizontal exits.

#### 7.2.4.2 Fire Compartments.

**7.2.4.2.1** Every fire compartment for which credit is permitted in connection with a horizontal exit(s) also shall have at least one additional exit, but not less than 50 percent of the required number and capacity of exits, that is not a horizontal exit, unless otherwise provided in 7.2.4.2.1.2.

**7.2.4.2.1.1** Any fire compartment not having an exit leading outside shall be considered as part of an adjoining compartment with an exit leading to the outside.

**7.2.4.2.1.2** The requirement of 7.2.4.2.1 shall not apply to the following:

- (1) Health care occupancies as otherwise provided in Chapters 18 and 19
- (2) Detention and correctional occupancies as otherwise provided in Chapters 22 and 23

**7.2.4.2.2** Every horizontal exit for which credit is permitted shall be arranged so that there are continuously available paths of travel leading from each side of the exit to stairways or other means of egress leading to outside the building.

**7.2.4.2.3** Wherever either side of a horizontal exit is occupied, the door leaves used in connection with the horizontal exit shall be unlocked from the egress side, unless otherwise permitted for the following:

- (1) Health care occupancies as provided in Chapters 18 and 19
- (2) Detention and correctional occupancies as provided in Chapters 22 and 23

**7.2.4.2.4** The floor area on either side of a horizontal exit shall be sufficient to hold the occupants of both floor areas and shall provide at least 3 ft<sup>2</sup> (0.28 m<sup>2</sup>) clear floor area per person, unless otherwise permitted for the following:

- (1) Health care occupancies as provided in Chapters 18 and 19
- (2) Detention and correctional occupancies as provided in Chapters 22 and 23

The design of a horizontal exit and the incorporation of a horizontal exit into a building are not complicated. For proper arrangement of the total means of egress system, it is simply a matter of designing each separated portion, or compartment, as if it were a completely separate single-story building. The point of passage through the door assembly in the horizontal exit is treated as if it were passage through an exterior exit door assembly. Egress capacity for each compartment is calculated to

accommodate the occupant load of the compartment before anyone leaves and before anyone from an adjacent compartment arrives.

Although each compartment must contain sufficient available floor area [at least 3 ft<sup>2</sup> (0.28 m<sup>2</sup>) per person for the total occupant load of both the compartment in question and the number of occupants from the adjacent compartment that are credited with traveling through the doors in the horizontal exit], such floor area is intended to serve as temporary refuge, as occupants are not expected to remain in the safe compartment indefinitely. Egress from the safe compartment continues through its other exits, such as enclosed exit stairs or door assemblies to the outside. The 2-hour fire resistance-rated barrier separating the safe compartment from the compartment of fire origin provides the additional time needed for all occupants to egress the building. Egress through other exits might be relatively slow, because such exits are typically sized for some portion of the initial occupant load of that safe compartment alone, not the combined load that includes occupants from other compartments. Occupants might have to queue and wait their turn to use these other, limited-capacity exits.

#### 7.2.4.3 Fire Barriers.

**7.2.4.3.1\*** Fire barriers separating buildings or areas between which there are horizontal exits shall meet both of the following requirements:

- (1) The barrier shall have a minimum 2-hour fire resistance rating, unless otherwise provided in 7.2.4.4.1.
- (2) The barrier shall provide a separation that is continuous to the finished ground level, unless otherwise provided in 7.2.4.3.2. (See also Section 8.3.)

**A.7.2.4.3.1** The continuity requirement of 7.2.4.3.1 does not prohibit the horizontal exit fire barrier from being offset on various floors. Where the floor assembly has a minimum 2-hour fire resistance rating and horizontal exit fire barrier walls are provided on all floors to the finished ground level, the continuity provision might be achieved by a combination of horizontal and vertical assemblies. For requirements regarding the alignment of fire barriers separating buildings of differing construction types, see 8.2.1.3.

**7.2.4.3.2\*** The separation required by 7.2.4.3.1(2) shall not be required to extend below the lowest level providing discharge to the exterior where both of the following are met:

- (1) Stories below the lowest level providing discharge to the exterior do not have a horizontal exit.
- (2) Stories below the lowest level providing discharge to the exterior are separated from the level above by a minimum of 2-hour fire resistance-rated construction.

**A.7.2.4.3.2** Figure A.7.2.4.3.2 depicts an example of the use of the exemption provided by 7.2.4.3.2.

Figure A.7.2.4.3.2 Example of Horizontal Exit Termination.

**7.2.4.3.3** Where a fire barrier provides a horizontal exit in any story of a building, such fire barrier shall not be required on other stories, provided that all of the following criteria are met:

- (1) The stories on which the fire barrier is omitted are separated from the story with the horizontal exit by construction having a fire resistance rating at least equal to that of the horizontal exit fire barrier.
- (2) Vertical openings between the story with the horizontal exit and the open fire area story are enclosed with construction having a fire resistance rating at least equal to that of the horizontal exit fire barrier.
- (3) All required exits, other than horizontal exits, discharge directly to the outside.

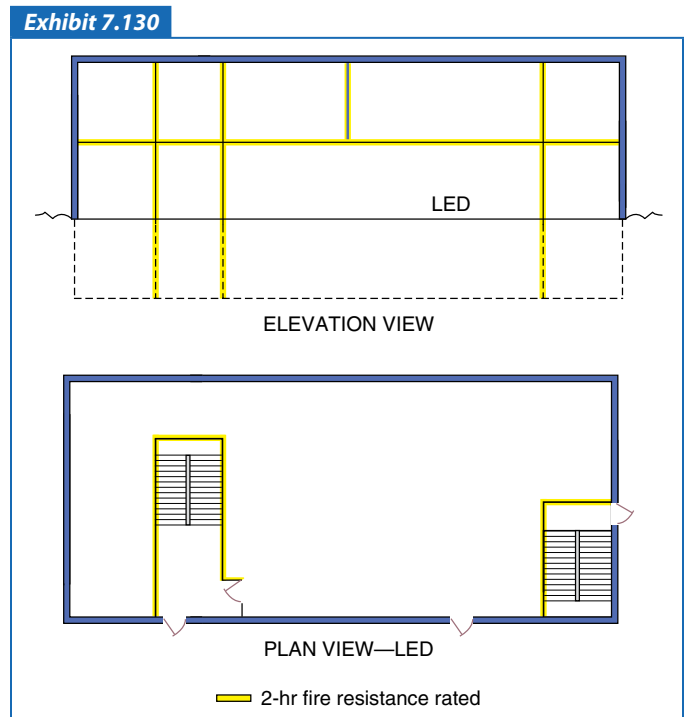

**Exhibit 7.129** illustrates the basic requirement of **7.2.4.3.1** that the 2-hour fire resistance-rated barrier extend vertically to the finished ground level, which in this case occurs one level below the level of exit discharge (LED) in the basement. **Exhibit 7.130** illustrates the use of the exemption of **7.2.4.3.3**, which has been available to *Code* users for many editions. The exemption detailed in **7.2.4.3.3** is used to avoid extending the 2-hour fire resistance-rated barrier vertically through all floors. A horizontal exit occurs only on the second floor. Fire-rated floor/ceiling assemblies and associated supporting construction (beams, girders, and columns) provide the required 2-hour fire resistance-rated separation between the second floor with horizontal exit and the LED and basement without horizontal exits. The exit stair enclosures are minimum 2-hour fire resistance-rated as protection for the vertical openings they create in accordance with **7.2.4.3.3(2)**. At the LED, an exit passageway is used at the left of the figure to fulfill the requirement of **7.2.4.3.3(3)** that all exits, other than the horizontal exit, discharge directly to the outside.

**Exhibit 7.131** illustrates the exemption offered by **7.2.4.3.2** — new to the 2015 edition of the *Code* — by which the horizontal exit need not extend below the lowest level providing discharge to the exterior (i.e., the LED in this case) where the story below (i.e., the basement) is separated from the LED by minimum 2-hour fire resistance-rated construction. Note that, unlike the case addressed in **Exhibit 7.130** where the exit stair

enclosure was required to be minimum 2-hour fire resistance-rated, the exit stair enclosure is permitted to be 1-hour fire resistance-rated in accordance with **7.1.3.2.1(1)**. Similarly, unlike the case addressed in **Exhibit 7.130** where all exit stairs were

Building with horizontal exits extending vertically to finished ground level.

Building with horizontal exit only on second floor.

Exhibit 7.131

Building with horizontal exit terminating at lowest story providing discharge to the exterior.

required to discharge directly outside in accordance with 7.2.4.3.3(3), the exit stair at the left is permitted to discharge onto the LED in accordance with 7.7.2.

**7.2.4.3.4** Where fire barriers serving horizontal exits, other than existing horizontal exits, terminate at outside walls, and the outside walls are at an angle of less than 180 degrees for a distance of 10 ft (3050 mm) on each side of the horizontal exit, the outside walls shall be protected by one of the following methods:

- (1) The outside walls shall have a minimum 1-hour fire resistance rating, with opening protectives having a minimum ¾-hour fire protection rating, for a distance of 10 ft (3050 mm) on each side of the horizontal exit.
- (2) One of the outside walls shall have a 2-hour fire resistance rating with opening protectives having a minimum 1½-hour fire protection rating, for a distance of 10 ft (3050 mm) from intersection with the horizontal exit.

Paragraph 7.2.4.3.4 requires additional protection where the horizontal exit wall joins the building's exterior wall if there is potential at that location for fire to spread to the adjoining fire compartment. Such potential is judged to exist where the building walls on each side of the horizontal exit expose each other at an angle of less than 180 degrees. The intent is the same as in 7.2.2.6.3 for the protection of exterior walls associated with outside stairs.

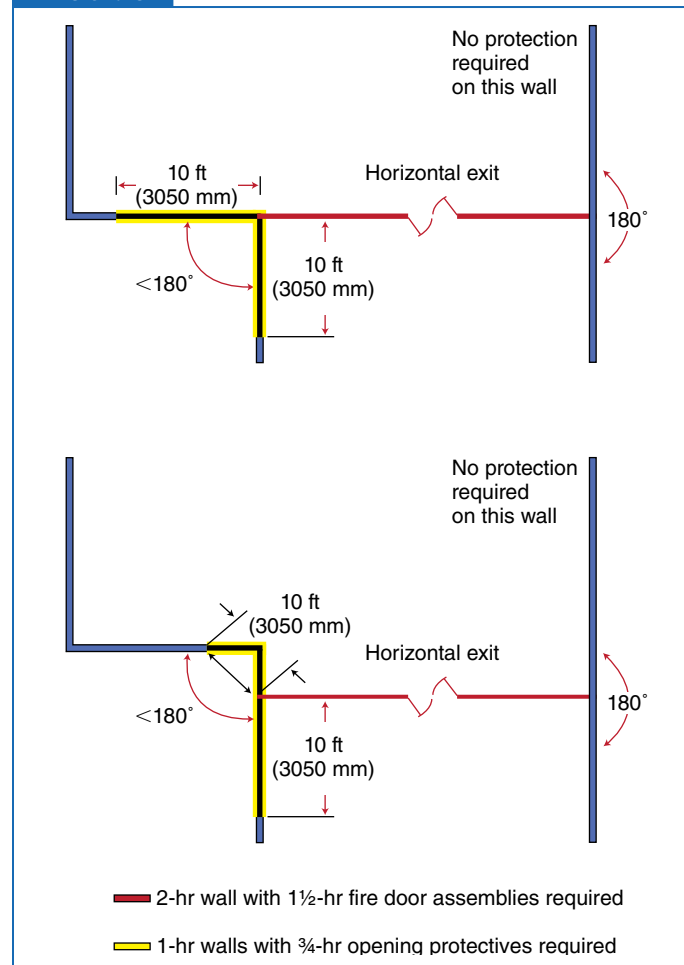

The traditional protection method, as offered by 7.2.4.3.4(1), requires the 10 ft (3050 mm) extensions to each side of the

2-hour fire resistance-rated horizontal exit to have a 1-hour fire resistance rating. One-hour fire resistance-rated walls are permitted to have ¾-hr fire protection-rated opening protectives; therefore, the rated extensions are permitted to use fire window assemblies where a 2-hour fire resistance-rated barrier is not (see Table 8.3.4.2).

The concept of the 180-degree rule is illustrated in Exhibit 7.132. Where the building walls on each side of the horizontal exit expose each other at an angle of less than 180 degrees, additional 10 ft (3050 mm), 1-hour fire protection-rated extensions to each side of the horizontal exit are provided in accordance with 7.2.4.3.4(1). At the right of Exhibit 7.132, additional protection is not required where the building walls at each side of the horizontal exit expose each other at a full 180 degrees.

Exhibit 7.133 illustrates the use of the protection option provided by 7.2.4.3.4(2), which is new to the 2015 edition of the Code. In lieu of providing a 1-hour fire resistance-rated exterior wall extension to both sides of the 2-hour fire resistance-rated

Exhibit 7.132

Protection of building exterior walls abutting a horizontal exit using two 1-hour fire-rated extensions.

Exhibit 7.133

Protection of building exterior walls abutting a horizontal exit using one 2-hour fire-rated extension.

horizontal exit barrier, a 2-hour fire resistance-rated exterior wall extension is provided to one side of the horizontal exit barrier. The Code text does not specify to which side of the horizontal exit fire barrier the fire-rated extension must be positioned. Exhibit 7.133 demonstrates both cases permitted by 7.2.4.3.4(2).

**7.2.4.3.5\*** Fire barriers forming horizontal exits shall not be penetrated by ducts, unless one of the following criteria is met:

- (1) The ducts are existing penetrations protected by approved and listed fire dampers.
- (2) The building is protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7.
- (3) The duct penetrations are those permitted in detention and correctional occupancies as otherwise provided in Chapters 22 and 23 and are protected by combination fire dampers/smoke leakage-rated dampers that meet the smoke damper actuation requirements of 8.5.5.

Paragraph 7.2.4.3.5 addresses horizontal exit barrier penetrations other than those provided for door assemblies used for accessing the adjacent fire compartments. Because horizontal exit barriers usually subdivide floor spaces, any prohibition on penetrations by ductwork complicates the design and installation of the heating, ventilating, and air-conditioning system.

Paragraph 7.2.4.3.5(1) recognizes existing ductwork penetrations only if the penetrations are protected by listed fire dampers that are also approved by the authority having jurisdiction.

Paragraph 7.2.4.3.5(2) provides for an acceptable level of safety and permits duct penetrations. Such penetrations are permitted if sprinklers protect the building throughout. The penetrating duct also requires an approved fire damper, because the horizontal exit is a 2-hour fire-rated barrier.

Paragraph 7.2.4.3.5(3) recognizes that local policy prohibits some detention and correctional occupancies from having automatic sprinkler protection. Nonsprinklered buildings are not permitted to use 7.2.4.3.5(2), yet horizontal exits are desirable means of egress features in this defend-in-place occupancy. Duct penetrations, therefore, are permitted if protected by combination fire/smoke leakage-rated dampers that meet the smoke damper actuation requirements of 8.5.5.

**A.7.2.4.3.5** The requirements of 7.2.4.3.5 are meant to apply to the horizontal and vertical portions of the fire barrier forming the horizontal exit.

**7.2.4.3.6** Any opening in the fire barriers specified in 7.2.4.3.5 shall be protected as provided in 8.3.4.

**7.2.4.3.7** Door assemblies in horizontal exits shall comply with 7.2.1.4, unless they are sliding door assemblies in industrial or storage occupancies as otherwise provided in Chapters 40 and 42.

An exemption for industrial occupancies in Chapter 40 and an exemption for storage occupancies in Chapter 42 permit a fire-rated sliding door assembly in addition to a swinging door assembly in a door opening in a horizontal exit. Such a door assembly might be installed for property protection, insurance-related reasons, or building code compliance. See 40.2.2.5.2 and 42.2.2.5.2.

**7.2.4.3.8** Unless otherwise specified in 7.2.4.3.8.1 and 7.2.4.3.8.2, swinging fire door assemblies shall be permitted in horizontal exits, provided that the criteria of both 7.2.4.3.8(1) and (2), or the criteria of both 7.2.4.3.8(1) and (3), are met as follows:

- (1) The door leaves shall swing in the direction of egress travel.
- (2) In other than sleeping room areas in detention and correctional occupancies, where a horizontal exit serves areas on both sides of a fire barrier, adjacent openings with swinging door leaves that open in opposite directions shall be provided, with signs on each side of the fire barrier identifying the door leaf that swings with the travel from that side.

(3) The door assemblies shall be of any other approved arrangement, provided that the door leaves always swing with any possible egress travel.

**7.2.4.3.8.1** The requirements of 7.2.4.3.8 shall not apply to horizontal exit door leaf swing as provided in Chapters 19 and 23.

**7.2.4.3.8.2** The requirements of 7.2.4.3.8 shall not apply to horizontal exit door assemblies in corridors not more than 6 ft (1830 mm) wide in existing buildings.

Paragraph 7.2.4.3.8.2 recognizes the impracticality and hardship of installing a pair of door leaves that meets the minimum width requirements of 7.2.1.2.3.2 in an opening across an existing corridor that is 6 ft (1830 mm) or less in width.

**7.2.4.3.9** Door leaves in horizontal exits shall be designed and installed to minimize air leakage. New door assemblies in horizontal exits shall be installed in accordance with NFPA 105, *Standard for Smoke Door Assemblies and Other Opening Protectives*.

Note that new door assemblies in horizontal exits are required to meet performance-based smoke leakage criteria contained in NFPA 105, *Standard for the Installation of Smoke Door Assemblies and Other Opening Protectives*, as well as the criterion of the first sentence of 7.2.4.3.9 related to minimization of air leakage. Existing door assemblies are evaluated qualitatively against the air leakage minimization criterion only.

**7.2.4.3.10\*** All fire door assemblies in horizontal exits shall be self-closing or automatic-closing in accordance with 7.2.1.8.

**A.7.2.4.3.10** Fusible link-actuated automatic-closing doors do not qualify for use in horizontal exits under these provisions, because smoke might pass through the opening before there is sufficient heat to release the hold-open device. Such doors are also objectionable because, once closed, they are difficult to open and would inhibit orderly egress.

**7.2.4.3.11** Horizontal exit door assemblies located across a corridor, other than approved existing door assemblies, shall be automatic-closing in accordance with 7.2.1.8.2.

Because cross-corridor door assemblies are so commonly wedged open in violation of Code requirements, 7.2.4.3.11 does not offer the option of using self-closing door assemblies but mandates the use of automatic-closing door assemblies in these horizontal exit, cross-corridor locations. Because the authority having jurisdiction can observe if the wedging open of door leaves has been a problem in existing installations, 7.2.4.3.11 gives the enforcer the authority to permit existing self-closing door assemblies to continue to be used.

**7.2.4.4 Bridges Serving Horizontal Exits Between Buildings.** The provisions of 7.2.4.4 shall apply to bridges serving horizontal exits between buildings and to the associated horizontal exit fire barrier.

**7.2.4.4.1** The minimum 2-hour fire resistance-rated barrier required by 7.2.4.3.1 shall extend as follows:

- (1) Vertically from the ground to a point 10 ft (3050 mm) above the bridge or to the roofline, whichever is lower
- (2) Horizontally for not less than 10 ft (3050 mm) to each side of the bridge

**7.2.4.4.2** Any opening in the fire barrier addressed in 7.2.4.4.1 shall be protected with fire door assemblies or fixed fire window assemblies having a ¾-hour fire protection rating, unless otherwise provided in 7.2.4.4.3.

**7.2.4.4.3** The requirement of 7.2.4.4.2 shall not apply to approved existing bridges.

**7.2.4.4.4** Where the bridge serves as a horizontal exit in one direction, the horizontal exit door leaf shall be required to swing only in the direction of egress travel, unless the door leaf complies with the swing requirements for the following:

- (1) Existing health care occupancies in Chapter 19
- (2) Existing detention and correctional occupancies in Chapter 23

**7.2.4.4.5** Where the bridge serves as a horizontal exit in both directions, door leaves shall be provided in pairs that swing in opposite directions, with only the door leaf swinging in the direction of egress travel included when determining egress capacity, unless otherwise provided in 7.2.4.4.5.1 through 7.2.4.4.5.3.

**7.2.4.4.5.1** Approved existing door assemblies on both ends of the bridge shall be permitted to swing out from the building.

**7.2.4.4.5.2** The requirement of 7.2.4.4.5 shall not apply to existing bridges if the bridge has sufficient floor area to accommodate the occupant load of either connected building or fire area based on 3 ft<sup>2</sup> (0.28 m<sup>2</sup>) per person.

**7.2.4.4.5.3** The requirement of 7.2.4.4.5 shall not apply to horizontal exit door leaf swing as provided for the following:

- (1) Existing health care occupancies in Chapter 19
- (2) Existing detention and correctional occupancies in Chapter 23

**7.2.4.4.6** Every bridge shall be not less than the width of the door opening to which it leads and shall be not less than 44 in. (1120 mm) wide for new construction.

**7.2.4.4.7** In climates subject to the accumulation of snow and ice, the bridge floor shall be protected to prevent the accumulation of snow and ice.

**7.2.4.4.8** In existing buildings, one step not exceeding 8 in. (205 mm) shall be permitted below the level of the inside floor.

## 7.2.5 Ramps.

Ramps are permitted as a part of a means of egress and are preferred over stairs under some circumstances. Exhibit 7.134 shows a ramp at the side of a stair.

Exhibit 7.134

Ramp at side of stair. (Photo courtesy of Jake Pauls)

**7.2.5.1 General.** Every ramp used as a component in a means of egress shall conform to the general requirements of Section 7.1 and to the special requirements of 7.2.5.

**7.2.5.2 Vehicle Ramps.** Vehicle ramps in parking structures, as permitted in 42.8.2.2.6, and not an accessible means of egress or other accessible element, shall be exempt from the provisions of 7.2.5.

The provision of 7.2.5.2 is new to the 2015 edition of the Code. Some vehicle ramps do not serve as part of an accessible means of egress or other accessible element. For example, there is a tightly curved circular ramp at the central parking garage at Boston Logan Airport that is used only for vehicle movement from level to level. Its pitch and other design features are far from compliant with the provisions of 7.2.5. Per the exemption offered by 7.2.5.2, such ramps are exempt from the provisions of 7.2.5. Parking structures are addressed in Section 42.8, and ramps within parking structures are addressed in 42.8.2.2.6.

**7.2.5.3 Dimensional Criteria.** The following dimensional criteria shall apply to ramps:

- (1) New ramps shall be in accordance with Table 7.2.5.3(a), unless otherwise permitted by the following:
  - (a) Table 7.2.5.3(a) shall not apply to industrial equipment access areas as provided in 40.2.5.3.
  - (b) The maximum slope requirement shall not apply to ramps in assembly occupancies as provided in Chapter 12.
  - (c) The maximum slope or maximum rise for a single ramp run shall not apply to ramps providing access to vehicles, vessels, mobile structures, and aircraft.
- (2) Existing ramps shall be permitted to remain in use or be rebuilt, provided that they meet the requirements shown in Table 7.2.5.3(b), unless otherwise permitted by any of the following:

- (a) The requirements of Table 7.2.5.3(b) shall not apply to industrial equipment access areas as provided in 40.2.5.3.
- (b) The maximum slope or maximum height between landings for a single ramp run shall not apply to ramps providing access to vehicles, vessels, mobile structures, and aircraft.
- (c) Approved existing ramps with slopes not steeper than 1 in 6 shall be permitted to remain in use.
- (d) Existing ramps with slopes not steeper than 1 in 10 shall not be required to be provided with landings.

Table 7.2.5.3(a) New Ramps

Feature	Dimensional Criteria	
	in.	mm
Minimum width clear of all obstructions, except projections not more than 4½ in. (114 mm) at or below handrail height on each side	44	1120
Maximum slope	1 in 12	
Maximum cross slope	1 in 48	
Maximum rise for a single ramp run	30	760

Table 7.2.5.3(b) Existing Ramps

Feature	Dimensional Criteria	
	ft/in.	mm
Minimum width	30 in.	760
Maximum slope	1 in 8	
Maximum height between landings	12 ft	3660

The dimensional criteria and other details applicable to ramps were extensively rewritten for the 1994 edition of the Code. In the 1994 and 1997 editions, the maximum allowed slope of a new ramp varied with the total vertical rise provided by the ramp. In each subsequent edition, the slope of new ramps has been limited to a maximum of 1 in 12. Such ramps are particularly useful for persons with severe mobility impairment. See ICC/ANSI A117.1, *American National Standard for Accessible and Usable Buildings and Facilities*. Paragraph 7.2.5.3(2) continues to recognize existing ramps and the rebuilding of existing ramps to the former criteria.

Paragraphs 7.2.5.3(1)(c) and 7.2.5.3(2)(b) recognize that ramps providing access to vehicles, vessels, mobile structures, and aircraft must be able to accommodate the variety of conditions encountered. For example, not all ships have entrances mounted at the same height, and, due to tidal influences, the water level rises and falls with respect to a stationary pier. Because ships are regulated under special rules, have their own exiting

**Exhibit 7.135**

Vessel-boarding ramp subject to differing slope. (Photo courtesy of Jake Pauls)

programs, and usually provide staff assistance during the disembarkation process, ramps to ships are exempt from the maximum ramp slope requirements of [Table 7.2.5.3\(a\)](#) and [Table 7.2.5.3\(b\)](#). [Exhibit 7.135](#) shows a ramp connecting the shore to a floating dock, making the ramp subject to differing slope.

#### 7.2.5.4 Ramp Details.

**7.2.5.4.1 Construction.** Ramp construction shall be as follows:

- (1) All ramps serving as required means of egress shall be of permanent fixed construction.
- (2) Each ramp in buildings required by this *Code* to be of Type I or Type II construction shall be any combination of noncombustible or limited-combustible material or fire-retardant-treated wood.
- (3) Ramps constructed with fire-retardant-treated wood shall be not more than 30 in. (760 mm) high, shall have an area of not more than 3000 ft<sup>2</sup> (277 m<sup>2</sup>), and shall not occupy more than 50 percent of the room area.
- (4) The ramp floor and landings shall be solid and without perforations.

**7.2.5.4.2 Landings.** Ramp landings shall be as follows:

- (1) Ramps shall have landings located at the top, at the bottom, and at door leaves opening onto the ramp.
- (2) The slope of the landing shall be not steeper than 1 in 48.
- (3) Every landing shall have a width not less than the width of the ramp.
- (4) Every landing, except as otherwise provided in [7.2.5.4.2\(5\)](#), shall be not less than 60 in. (1525 mm) long in the direction of travel, unless the landing is an approved existing landing.
- (5) Where the ramp is not part of an accessible route, the ramp landings shall not be required to exceed 48 in. (1220 mm)

in the direction of travel, provided that the ramp has a straight run.

- (6) Any changes in travel direction shall be made only at landings, unless the ramp is an existing ramp.
- (7) Ramps and intermediate landings shall continue with no decrease in width along the direction of egress travel.

Landings are required to be nearly horizontal to provide transition areas to and from ramps that are usable to persons with severe mobility impairments (see [3.3.246](#)). Landings at door openings allow for movement through the door opening without the burden of dealing with a sloping floor section. The requirement for intermediate landings on ramps is similar to that part of [7.2.2.3.2](#) applicable to landings on stairs.

The minimum 60 in. (1525 mm) landing depth, measured in the direction of travel, is intended to accommodate a person in a wheelchair. Thus, [7.2.5.4.2\(5\)](#) permits the landing depth on straight run portions of the ramp to be decreased to 48 in. (1220 mm) where the ramp is not part of an accessible route (see [3.3.3](#)).

The effect of [7.2.5.4.2\(6\)](#) is to prohibit curved ramps. With a curved ramp, the travel direction changes continually. The change in direction is accomplished by introducing a cross slope that might make use of the ramp by persons with severe mobility impairments overly burdensome. Thus, the *Code* requires that any changes in travel direction occur only at level landings.

**7.2.5.4.3 Drop-Offs.** Ramps and landings with drop-offs shall have curbs, walls, railings, or projecting surfaces that prevent people from traveling off the edge of the ramp. Curbs or barriers shall be not less than 4 in. (100 mm) in height.

#### 7.2.5.5 Guards and Handrails.

**7.2.5.5.1** Guards complying with [7.2.2.4](#) shall be provided for ramps, unless otherwise provided in [7.2.5.5.4](#).

**7.2.5.5.2** Handrails complying with [7.2.2.4](#) shall be provided along both sides of a ramp run with a rise greater than 6 in. (150 mm), unless otherwise provided in [7.2.5.5.4](#).

**7.2.5.5.3** The height of handrails and guards shall be measured vertically to the top of the guard or rail from the walking surface adjacent thereto.

**7.2.5.5.4** The requirements of [7.2.5.5.1](#) and [7.2.5.5.2](#) shall not apply to guards and handrails provided for ramped aisles in assembly occupancies as otherwise provided in [Chapters 12](#) and [13](#).

Ramps are subject to the guard and handrail requirements of [7.2.2.4](#). However, per [7.2.5.5.2](#), the handrail requirements apply only to ramps with a rise of more than 6 in. (150 mm). [Exhibit 7.136](#) shows a well-lighted indoor ramp with handrails and effective marking at top and bottom.

**7.2.5.6 Enclosure and Protection of Ramps.** Ramps in a required means of egress shall be enclosed or protected as a stair in accordance with [7.2.2.5](#) and [7.2.2.6](#).

Exhibit 7.136

Effectively marked and lighted indoor ramp with handrails. (Photo courtesy of Jake Pauls)

### 7.2.5.7 Special Provisions for Outside Ramps.

Outside ramps are permitted to serve as part of a means of egress, subject to the applicable criteria governing exit access, exits, and exit discharge.

**7.2.5.7.1\* Visual Protection.** Outside ramps shall be arranged to avoid any impediments to their use by persons having a fear of high places. Outside ramps more than 36 ft (11 m) above the finished ground level shall be provided with an opaque visual obstruction not less than 48 in. (1220 mm) in height.

**A.7.2.5.7.1** The guards required by 7.1.8 and detailed in 7.2.2.4.5 for the unenclosed sides of ramps will usually meet this requirement where the ramp is not more than 36 ft (11 m) above the finished ground level. Special architectural treatment, including application of such devices as metal or masonry screens and grilles, will usually be necessary to comply with the intent of the requirements for ramps over 36 ft (11 m) above the finished ground level.

**7.2.5.7.2\* Water Accumulation.** Outside ramps and landings shall be designed to minimize water accumulation on their surfaces.

**A.7.2.5.7.2** Providing a pitch of  $\frac{1}{8}$  in./ft to  $\frac{1}{4}$  in./ft (10 mm/m to 21 mm/m) will aid the shedding of water from a nominally horizontal surface.

### 7.2.6\* Exit Passageways.

**A.7.2.6** An exit passageway serves as a horizontal means of exit travel that is protected from fire in a manner similar to an enclosed interior exit stair. Where it is desired to offset exit stairs in a multistory building, an exit passageway can be used to preserve the continuity of the protected exit by connecting the bottom of one stair to the top of the stair that continues to the street floor. Probably the most important use of an exit passageway is to

satisfy the requirement that at least 50 percent of the exit stairs discharge directly outside from multistory buildings (see 7.7.2). Thus, if it is impractical to locate the stair on an exterior wall, an exit passageway can be connected to the bottom of the stair to convey the occupants safely to an outside exit door. In buildings of extremely large area, such as shopping malls and some factories, the exit passageway can be used to advantage where the travel distance to reach an exit would otherwise be excessive.

The word “exit,” used in the term *exit passageway*, helps to distinguish between an exit passageway and an ordinary passageway or corridor that serves as exit access. An exit passageway is an exit; it provides a path of travel offering the same level of protection and safety that is required of an enclosed exit stair. An exit passageway is a versatile feature, because it can be used to extend an exit, or, as is done in many cases, it can be used to bring an exit closer to where the occupants are located.

In Exhibit 7.137, an exit passageway is used to continue the exit to the outside from one of the two enclosed interior exit stairs. This arrangement might be used to help comply with the requirements of 7.7.2, which mandate that at least one-half of the egress capacity and at least one-half of the number of exits must discharge directly to the outside at interior discharge levels.

Extending the exit stair’s required enclosure to include a portion of the corridor creates an exit passageway that brings the exit closer to the occupants, as is demonstrated in

Exhibit 7.137

Exit passageway used to connect exit stair with exterior of building.

Exhibit 7.138

Exit passageway used to keep travel distance from becoming excessive.

Exhibit 7.139

Exit passageways used for multiple purposes in mall building.

**Exhibit 7.138.** Travel distance measurement ends at entrance E1 to the exit passageway. The distance from X to E2 exceeds the allowed travel distance. The distance from X to E1 is within the allowed travel distance. Extension of an exit stair's enclosure is often used where travel distance to the exit enclosure would otherwise be in excess of Code allowance. Because it is an exit, an exit passageway qualifies as the point at which travel distance measurement ends in accordance with Section 7.6.

In Exhibit 7.139, the two exit passageways marked A bring exits within allowable travel distances for the occupants in the mall (similar to the exit passageway illustrated in Exhibit 7.138). The exit passageway marked B allows occupants of multiple stores in the mall to enter the exit directly from the rear of each store. This arrangement is often used to limit, for security purposes, the number of door assemblies that open directly to the outside.

**7.2.6.1\* General.** Exit passageways used as exit components shall conform to the general requirements of Section 7.1 and to the special requirements of 7.2.6.

**A.7.2.6.1** Examples of building elements that might be arranged as exit passageways include hallways, corridors, passages, tunnels, underfloor passageways, or overhead passageways.

**7.2.6.2 Enclosure.** An exit passageway shall be separated from other parts of the building as specified in 7.1.3.2, and the following alternatives shall be permitted:

- (1) Fire windows in accordance with 8.3.3 shall be permitted to be installed in the separation in a building protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7.
- (2) Existing fixed wired glass panels in steel sash shall be permitted to be continued in use in the separation in buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7.

**7.2.6.3 Stair Discharge.** An exit passageway that serves as a discharge from a stair enclosure shall have not less than the same fire resistance rating and opening protective fire protection rating as those required for the stair enclosure.

Paragraph 7.2.6.2 requires exit passageways to have walls with the hourly fire resistance ratings and door assemblies with the fire protection ratings required of exit stair enclosures, as detailed in 7.1.3.2.1(1) or (2) and 8.3.4.2. The requirement also limits door openings into, and penetrations through, the exit enclosure created by the exit passageway, as detailed in 7.1.3.2.1(9) and (10). In Exhibit 7.140, new exit passageway A on the first floor — the level of exit discharge — opens at one end to a five-story exit stair enclosure and, at the other end, to a door assembly to the outside. This exit passageway also serves as a horizontal continuation of, and discharge for, the stair enclosure. In serving as a discharge for the exit stair, the exit passageway must provide the same degree of protection required of the stair enclosure. Given that the exit stair must be enclosed by 2-hour fire resistance-rated construction because it is new and serves four or more stories, the exit passageway must also be enclosed by 2-hour fire resistance-rated construction. This protection is addressed in 7.2.6.3.

In Exhibit 7.140, exit passageway A and the five-story exit stair enclosure that it serves each have a 2-hour fire resistance rating as discussed in the preceding paragraph. The door shown between the exit stair enclosure and the exit passageway is not required. In other words, the exit passageway is permitted to be open to the exit stair enclosure. If the exit stair enclosure and exit passageway are open to each other, the exit passageway is not permitted to have fire windows, as the exit stair enclosure is not permitted to have fire windows [see 7.1.3.2.1(9)]. If they are separated from each other as shown in Exhibit 7.140, the exit passageway is permitted to have fire windows in accordance with 7.2.6.2(1) if the building is sprinklered.

In Exhibit 7.140, exit passageway B, on the fourth floor, is used to provide the safety of an exit to occupants traveling to the exit stair enclosure. This exit passageway might have been built to meet the travel distance limitation. If a fire-rated wall and door assembly separate exit passageway B from the new 2-hour exit stair enclosure, the required rating of exit passageway B is only 1 hour, because the exit passageway serves only the occupants of the fourth floor. A similar 1-hour fire resistance-rated enclosure requirement applies, for example, to a horizontal exit serving a single story of a shopping mall building. Contrast this configuration with exit passageway A on the first floor, which

Exhibit 7.140

Exit passageways with fire resistance-rated enclosures and fire protection-rated door assemblies.

potentially serves occupants of the second through fifth floors and must provide a continuation of the 2-hour separation required of the new stair enclosure.

For the same reasons that the exit stair enclosure cannot have door assemblies opening directly onto it from normally unoccupied spaces, a storage room, for example, is prohibited from opening directly onto exit passageways A and B and the exit stair enclosures. Penetrations through the enclosing walls are limited to those necessary for the functioning of life safety systems, such as lighting powered by electrical cables that enter the exit enclosure via properly sealed conduit penetrations. Ductwork for climate control is prohibited from penetrating enclosing walls. Thus, the exit passageways and the exit stair enclosures must receive their heating and cooling by systems independent of those serving the remainder of the building. Ductwork serving other parts of the floor must be routed around the outside of, not through, the exit passageway enclosures.

#### 7.2.6.4 Width.

**7.2.6.4.1** The width of an exit passageway shall be sized to accommodate the aggregate required capacity of all exits that

discharge through it, unless one of the following conditions applies:

- (1)\* Where an exit passageway serves occupants of the level of exit discharge as well as other stories, the capacity shall not be required to be aggregated.

**A.7.2.6.4.1(1)** Where an exit passageway serves occupants on the level of exit discharge as well as other floors, it should not be required that the occupant loads be added, thus increasing the width of the exit passageway. The situation is the same as that in which occupants from the level of exit discharge join occupants from upper floors for a few feet of horizontal travel through a stair enclosure.

- (2) As provided in [Chapters 36 and 37](#), an exit passageway in a mall building shall be permitted to accommodate occupant loads independently from the mall and the tenant spaces. (See [36.2.2.7.2](#) and [37.2.2.7.2](#).)

The text in [A.7.2.6.4.1\(1\)](#) explains the exemption to aggregating the capacity of exit passageways where accommodating occupant loads from various floors. See [A.36.2.2.7.2](#) and the commentary associated with [36.2.2.7.2](#) (which is positioned within the large block of commentary after [36.2.2.12.2](#) and [37.2.2.12.2](#)) for a detailed explanation of the situation permitted in mall buildings by [7.2.6.4.1\(2\)](#).

**7.2.6.4.2** In new construction, the minimum width of any exit passageway into which an exit stair discharges, or that serves as a horizontal transfer within an exit stair system, shall meet the following criteria:

- (1) The minimum width of the exit passageway shall be not less than two-thirds of the width of the exit stair.
- (2) Where stairs are credited with egress capacity in accordance with [7.3.3.2](#), the exit passageway width shall be sized to accommodate the same capacity as the stair, with such capacity determined by use of the capacity factors in [Table 7.3.3.1](#).

Level travel through exit passageways is typically calculated using a capacity factor of 0.2 in. (5 mm) per person, and stair travel width is typically calculated using a capacity factor of 0.3 in. (7.6 mm) per person in accordance with [Table 7.3.3.1](#). The provision of [7.2.6.4.2\(1\)](#) maintains the 2:3 ratio derived from comparing the two capacity factors and might seem redundant with the requirements of [7.3.3.1](#). It is presented as part of [7.2.6.4.2](#) to provide a foundation on which the provision of [7.2.6.4.2\(2\)](#) builds. The provision of [7.2.6.4.2\(2\)](#) provides guidance on how to size the exit passageway that serves a stair that utilizes the enhanced capacity provisions of [7.3.3.2](#). See the commentary that follows [A.7.3.3.2](#).

**7.2.6.5 Floor.** The floor shall be solid and without perforations.

**7.2.7 Escalators and Moving Walks.** Escalators and moving walks shall not constitute a part of the required means of

**Exhibit 7.141***Curved escalator in mall building. (Photo courtesy of Jake Pauls)*

egress, unless they are previously approved existing escalators and moving walks.

Escalators are effectively used to move people vertically for short distances, especially in malls, transportation centers, and other assembly venues. **Exhibit 7.141** shows a curved escalator in a mall building. Only previously approved existing escalators and moving walks are permitted to serve as part of the required egress.

Older editions of the *Code* permitted some egress capacity credit for escalators. The riser height and tread depth vary near the floor landings, as the tread sections appear and disappear into the floor, making it difficult to walk on a stopped escalator. **Exhibit 7.142** shows the irregularity in riser height near the top of an escalator run. Also, because riser/tread sections of escalators and standing surfaces of moving walks are removed for maintenance, it cannot be ensured that occupants will be able to walk on these devices when emergency egress is needed. Therefore, new escalators and moving walks receive no credit within the required means of egress. Existing, previously approved escalators and moving walks are permitted to continue to be used as part of the means of egress if permitted by the appropriate occupancy chapter. Although not permitted as part of the required means of egress in new construction, new escalators and moving walks, where installed, must comply with ASME A17.1/CSA B44, *Safety Code for Elevators and Escalators*, and existing escalators and moving walks must comply with ASME A17.3, *Safety Code for Existing Elevators and Escalators*.<sup>17</sup> See **9.4.2.1** and **9.4.2.2**.

Escalators are acceptable as an egress component in existing buildings only in the following occupancies:

1. Existing assembly occupancies (**13.2.2.8**)
2. Existing ambulatory health care occupancies (**21.2.2.8**)
3. Existing hotels and dormitories (**29.2.2.8**)
4. Existing apartment buildings (**31.2.2.8**)
5. Existing mercantile occupancies (**37.2.2.8**)

**Exhibit 7.142***Irregularity in riser height near top of escalator run.*

6. Existing business occupancies (**39.2.2.8**)
7. Existing industrial occupancies (**40.2.2.8**)

When evaluating existing escalators for occupant egress, the factors that follow should be considered.

1. The escalator should comply with the applicable requirements for stairs in **7.2.2**. It is assumed that, where escalators serve as required means of egress, they will continue to operate in case of fire. However, if they stop due to electric current failure or other cause, they can be used as ordinary stairs.

2. Escalators constituting a means of egress should operate only in the direction of egress. Usually escalators are provided in pairs, with one stairway moving up and another moving down; however, if the electric power fails and both stop, two stairs would be available for movement in the egress direction. In this situation, one might propose that both stairways be accepted as constituting a means of egress, since the power could be turned off intentionally. The problem is that, in an emergency, the power might not be turned off, and one stairway would continue to move against traffic. For this reason, only those escalators moving in the direction of egress should be permitted to be part of a means of egress.

3. Escalators should be of the horizontal-tread type and, with the exception of step tread surfaces, handrails, and step wheels, should be of noncombustible construction throughout.

4. A single escalator that is 32 in. (810 mm) wide should be given credit for 75 people. An escalator that is 48 in. (1220 mm) wide should be given credit for 150 people. Even though a person does not have to exert any energy or do any moving while on an operating escalator, there are many people who are frightened by escalators and many who are extremely cautious in approaching them. These are factors that could contribute to a bottleneck as user movement is impeded. Thus, it is recognized that an escalator would have to be wider than a stair to accommodate the same number of people.

5. There should be unobstructed spaces of at least 4 in. (100 mm) outside the handrail and above the handrail for the full length of the escalator.

6. No single escalator should travel uninterrupted for more than one story.

The guidelines of 1 through 6 in this commentary were taken from older editions of the *Code* and were required in those years when escalators were given egress credit in new construction. They are offered here as guidance for existing escalator installations credited with serving within the means of egress.

Even in an existing building, an escalator cannot be counted as an exit unless it is enclosed as an exit in accordance with 7.1.3.2. Such an arrangement is rare. Typically, an existing escalator is not enclosed and might, at most, serve as exit access or exit discharge.

Most of the same principles that apply to the design and operation of escalators also apply when evaluating existing moving walks. The major difference is that a moving walk that moves in the direction of egress travel can be evaluated in terms of the usual egress width and associated capacity rather than the larger dimensions specified for escalators in item 4 of this commentary.

### 7.2.8 Fire Escape Stairs.

Fire escape stairs and ladders have fallen into disfavor for a variety of reasons, including the following:

1. Unsightly appearance
2. Possible icing in winter weather
3. Expense of maintenance (i.e., the metal is subject to corrosion)
4. Possibility of users being trapped by a fire issuing from unprotected openings at a lower level
5. Fear of height and, therefore, objection to using fire escape stairs and ladders

On the other hand, well-maintained fire escape stairs can and have saved many lives when smoke-filled stairs have become impassable. A classic example is the June 5, 1946, fire in the 22-story LaSalle Hotel in Chicago. Hundreds of people made their escape from the building on outside fire escape stairs.<sup>18</sup>

In the past, fire fighters have found outside fire escape stairs advantageous. However, instances can be cited where corroded fire escapes have collapsed, or where people have been fatally burned because fire broke out of windows or door assemblies at a lower level as they were descending on a fire escape. The *Code* requires proper means of egress using interior or outside stairs and the gradual phasing out of fire escape stairs as new buildings replace existing buildings.

#### 7.2.8.1 General.

**7.2.8.1.1** Where permitted in Chapters 11 through 43, fire escape stairs shall comply with the provisions of 7.2.8, unless they are approved existing fire escape stairs.

Fire escape stairs, as specified in 7.2.8 of the *Code*, should not be confused with the outside stairs covered in 7.2.2. Neither should the fire escape stairs specified by 7.2.8 of the *Code* be confused with the inferior fire escapes that are commonly found on old buildings. Such steep, inadequate, and flimsy fire escapes, unshielded against fire in the structure to which they are attached, might give an occupant a false sense of security. Such escape stairs are not recognized by this *Code*.

Even the fire escape stairs constructed in accordance with this *Code* have limitations that might prevent their effective use during a fire. Even where window protection is provided, conditions might be such that fire, or the smoke from fire, on lower floors might render the stairs impassable before the occupants of the upper floors have had time to use them. Fire escape stairs might be blocked by snow or ice when they are most needed. People are likely to be timid about descending fire escape stairs from a considerable height, so their downward travel is much slower than for travel on inside stairs. Slower travel is a factor even where *Code*-specified solid-tread stairs without perforations are used in place of ordinary slatted-tread construction. Fire escape stairs are not the usual means of egress. Occupants of buildings will not use them as readily in the case of fire as they will an inside stair, which is the more common egress component. Because fire escape stairs are an emergency device and are not ordinarily used, their proper upkeep is often neglected.

Fire escape stairs are acceptable as an egress component in existing buildings only in the following occupancies:

1. Existing assembly occupancies (13.2.2.9)
2. Existing detention and correctional occupancies (23.2.2.8)
3. Existing hotels and dormitories (29.2.2.9)
4. Existing apartment buildings (31.2.2.9)
5. Existing mercantile occupancies (37.2.2.9)
6. Existing business occupancies (39.2.2.9)
7. Existing industrial occupancies (40.2.2.9)
8. Existing storage occupancies (42.2.2.8)

**7.2.8.1.2** Fire escape stairs shall not constitute any of the required means of egress, unless otherwise provided in 7.2.8.1.2.1 and 7.2.8.1.2.2.

**7.2.8.1.2.1** Fire escape stairs shall be permitted on existing buildings as provided in Chapters 11 through 43 but shall not constitute more than 50 percent of the required means of egress.

**7.2.8.1.2.2** New fire escape stairs shall be permitted to be erected on existing buildings only where the authority having jurisdiction has determined that outside stairs are impractical. (See 7.2.2.)

**7.2.8.1.2.3** New fire escape stairs permitted by 7.2.8.1.2.2 shall not incorporate ladders or access windows, regardless of occupancy classification or occupant load served.

No recognition of any kind is given by the *Code* to the use of fire escape stairs in new buildings for any of the three parts of a means of egress. A limited recognition of 50 percent of egress capacity is given for their use in existing buildings of the

occupancy types listed in the commentary following 7.2.8.1.1, simply because the fire escape stairs have already been installed or because such stairs might be the only feasible way in which to upgrade a means of egress in an existing building.

In most cases, outside stairs complying with 7.2.2 must be used rather than fire escape stairs. However, the Code recognizes that, in the case of some existing buildings, there are situations in which modifying stairs to comply with 7.2.2 would be impractical. For example, the space between the building and the property line might be too narrow to accommodate a Code-conforming stair, or it might be necessary to have the stair located over a sidewalk, alley, or similar space that cannot be permanently blocked by stair construction.

Fire escape stairs are regarded as an expedient remedy for deficiencies in the means of egress of existing buildings where it might not be feasible to provide outside stairs or properly enclosed, additional, inside stairways required by the Code.

Because effective use of fire escape stairs might be seriously impaired by conditions such as snow and ice, the authorities having jurisdiction might wish to impose additional requirements because of climate. In such a case, egress capacity credit for the fire escape stairs might be reduced.

**7.2.8.1.3** Fire escape stairs of the return-platform type with superimposed runs, or of the straight-run type with a platform that continues in the same direction, shall be permitted. Either type shall be permitted to be parallel to, or at right angles to, buildings. Either type shall be permitted to be attached to buildings or erected independently of buildings and connected by walkways.

**7.2.8.2 Protection of Openings.** Fire escape stairs shall be exposed to the smallest possible number of window and door openings, and each opening shall be protected with approved fire door or fire window assemblies where the opening or any portion of the opening is located as follows:

- (1) Horizontally, within 15 ft (4570 mm) of any balcony, platform, or stairway constituting a component of the fire escape stair
- (2) Below, within three stories or 36 ft (11 m) of any balcony, platform, walkway, or stairway constituting a component of the fire escape stair, or within two stories or 24 ft (7320 mm) of a platform or walkway leading from any story to the fire escape stair
- (3) Above, within 10 ft (3050 mm) of any balcony, platform, or walkway, as measured vertically, or within 10 ft (3050 mm) of any stair tread surface, as measured vertically
- (4) Facing a court served by a fire escape stair, where the least dimension of the court does not exceed one-third of the height to the uppermost platform of the fire escape stair, measured from the finished ground level
- (5) Facing an alcove served by a fire escape stair, where the width of the alcove does not exceed one-third, or the depth of the alcove does not exceed one-fourth, of the height to

the uppermost platform of the fire escape stair, measured from the finished ground level

**7.2.8.2.1** The requirements of 7.2.8.2 shall not apply to openings located on the top story where stairs do not lead to the roof.

**7.2.8.2.2** The requirements of 7.2.8.2 shall be permitted to be modified by the authority having jurisdiction where automatic sprinkler protection is provided, where the occupancy is limited to low hazard contents, or where other special conditions exist.

**7.2.8.2.3** The requirements of 7.2.8.2 for the protection of window openings shall not apply where such window openings are necessary for access to existing fire escape stairs.

### 7.2.8.3 Access.

**7.2.8.3.1** Access to fire escape stairs shall be in accordance with 7.2.8.4 and 7.5.1.1.1 through 7.5.1.2.2.

Exhibit 7.143 illustrates the minimum opening dimensions for windows that open onto fire escape stairs serving more than 10 occupants. The exhibit also depicts the maximum interior measurements from the floor to the windowsill. See Table 7.2.8.4(a) and Table 7.2.8.4(b).

Window openings for access to fire escape stairs.

**7.2.8.3.2** Where access is permitted by way of windows, the windows shall be arranged and maintained so as to be easily opened. Screening or storm windows that restrict free access to the fire escape stair shall be prohibited.

**7.2.8.3.3** Fire escape stairs shall extend to the roof in all cases where the roof is subject to occupancy or provides an area of safe refuge, unless otherwise provided in 7.2.8.3.4.

**7.2.8.3.4** Where a roof has a pitch that does not exceed 1 to 6, fire escape ladders in accordance with 7.2.9 or alternating tread devices in accordance with 7.2.11 shall be permitted to provide access to the roof.

**7.2.8.3.5** Access to a fire escape stair shall be directly to a balcony, landing, or platform; shall not exceed the floor or

windowsill level; and shall not be more than 8 in. (205 mm) below the floor level or 18 in. (455 mm) below the windowsill level.

The height requirements of 7.2.8.3.5 establish the maximum distance, on the outside of the building, down to the balcony, landing, or platform of the fire escape stair, measured from the windowsill level or from the floor level.

**7.2.8.4 Stair Details.** Fire escape stairs shall comply with the requirements of Table 7.2.8.4(a). Replacement of fire escape stairs shall comply with the requirements of Table 7.2.8.4(b).

Generally, the requirements for fire escape stairs are similar to those specified for outside stairs. The major difference between the two types of stairs is the dimensions in Commentary Table 7.1, which details the differences between the generally accepted fire escape stair of existing buildings and the lighter fire escape stair considered acceptable for small existing buildings serving 10 or fewer occupants.

The existing fire escape stair with a minimum width of 22 in. (560 mm) is a type that is permitted for buildings of small or moderate size, depending on the specific features of an installation.

The existing fire escape stair with a minimum width of 18 in. (455 mm) represents the absolute minimum that is permitted. Because of access over windowsills, steep pitch, and a narrow width, travel down such stairs will be necessarily slow and possibly dangerous. Even worse are stairs with spiral stair treads or stairs that terminate at a balcony above ground level with a fixed or movable ladder extending downward from the balcony. Such stairs are suitable only in situations that involve a very small number of occupants.

#### 7.2.8.5 Guards, Handrails, and Visual Enclosures.

**7.2.8.5.1** All fire escape stairs shall have walls or guards and handrails on both sides in accordance with 7.2.2.4.

**7.2.8.5.2** Replacement fire escape stairs in occupancies serving more than 10 occupants shall have visual enclosures to avoid any

**Table 7.2.8.4(a) Fire Escape Stairs**

Feature	Serving More Than 10 Occupants	Serving 10 or Fewer Occupants
Minimum widths	22 in. (560 mm) clear between rails	18 in. (455 mm) clear between rails
Minimum horizontal dimension of any landing or platform	22 in. (560 mm) clear	18 in. (455 mm) clear
Maximum riser height	9 in. (230 mm)	12 in. (305 mm)
Minimum tread, exclusive of nosing	9 in. (230 mm)	6 in. (150 mm)
Minimum nosing or projection	1 in. (25 mm)	No requirement
Tread construction	Solid ½ in. (13 mm) diameter perforations permitted	Flat metal bars on edge or square bars secured against turning, spaced 1¼ in. (32 mm) maximum on centers
Winders	None	Permitted subject to capacity penalty
Risers	None	No requirement
Spiral	None	Permitted subject to capacity penalty
Maximum height between landings	12 ft (3660 mm)	No requirement
Minimum headroom	6 ft 8 in. (2030 mm)	6 ft 8 in. (2030 mm)
Access to escape	Door or casement windows, 24 in. × 6 ft 8 in. (610 mm × 1980 mm); or double-hung windows, 30 in. × 36 in. (760 mm × 915 mm) clear opening	Windows providing a clear opening of at least 20 in. (510 mm) in width, 24 in. (610 mm) in height, and 5.7 ft <sup>2</sup> (0.53 m <sup>2</sup> ) in area
Level of access opening	Not over 12 in. (305 mm) above floor; steps if higher	Not over 12 in. (305 mm) above floor; steps if higher
Discharge to the finished ground level	Swinging stair section permitted if approved by authority having jurisdiction	Swinging stair, or ladder if approved by authority having jurisdiction
Capacity	½ in. (13 mm) per person, if access by door; 1 in. (25 mm) per person, if access by climbing over windowsill	10 persons; if winders or ladder from bottom balcony, 5 persons; if both, 1 person

**Table 7.2.8.4(b) Replacement Fire Escape Stairs**

Feature	Serving More Than 10 Occupants	Serving 10 or Fewer Occupants
Minimum widths	22 in. (560 mm) clear between rails	22 in. (560 mm) clear between rails
Minimum horizontal dimension of any landing or platform	22 in. (560 mm)	22 in. (560 mm)
Maximum riser height	9 in. (230 mm)	9 in. (230 mm)
Minimum tread, exclusive of nosing	10 in. (255 mm)	10 in. (255 mm)
Tread construction	Solid, ½ in. (13 mm) diameter perforations permitted	Solid, ½ in. (13 mm) diameter perforations permitted
Winders	None	Permitted subject to 7.2.2.2.4
Spiral	None	Permitted subject to 7.2.2.2.3
Risers	None	None
Maximum height between landings	12 ft (3660 mm)	12 ft (3660 mm)
Minimum headroom	6 ft 8 in. (2030 mm)	6 ft 8 in. (2030 mm)
Access to escape	Door or casement windows, 24 in. × 6 ft 8 in. (610 mm × 1980 mm); or double-hung windows, 30 in. × 36 in. (760 mm × 915 mm) clear opening	Windows providing a clear opening of at least 20 in. (510 mm) in width, 24 in. (610 mm) in height, and 5.7 ft <sup>2</sup> (0.53 m <sup>2</sup> ) in area
Level of access opening	Not over 12 in. (305 mm) above floor; steps if higher	Not over 12 in. (305 mm) above floor; steps if higher
Discharge to the finished ground level	Swinging stair section permitted if approved by authority having jurisdiction	Swinging stair section permitted if approved by authority having jurisdiction
Capacity	½ in. (13 mm) per person, if access by door; 1 in. (25 mm) per person, if access by climbing over windowsill	10 persons

**Commentary Table 7.1 Differences Between Outside Stairs and Fire Escape Stairs**

Design Factor	New Outside Stair	Existing Outside Stair	Fire Escape Stair	
			Standard	Small Buildings
Accepted as means of egress	Yes	Yes	Existing buildings	Existing buildings
Width	44 in. (1120 mm) <sup>†</sup>	44 in. (1120 mm) <sup>†</sup>	22 in. (560 mm)	18 in. (455 mm)
Maximum rise	7 in. (180 mm)	8 in. (205 mm)	9 in. (230 mm)	12 in. (305 mm)
Minimum tread	11 in. (280 mm)	9 in. (230 mm)	9 in. (230 mm)	6 in. (150 mm)
Tread construction	Solid	Solid, perforations permitted	Solid, perforations permitted	Metal bars
Access by windows	No	No	Yes	Yes
Swinging stair accepted	No	No	Yes	Yes
Ladder accepted	No	No	No	Yes

Note: The capacity of normal fire escape stairs is 45 persons if accessed by door assemblies, and 20 persons if accessed by windows where it is necessary to climb over a sill. On small buildings, the capacity is 10 persons; 5 persons if winders or a ladder from bottom landing; 1 person if both winders and a ladder from bottom landing.

<sup>†</sup>36 in. (915 mm) where serving occupant load of fewer than 50.

impediments to their use by persons having a fear of high places. Fire escape stairs more than 36 ft (11 m) above the finished ground level shall be provided with an opaque visual obstruction not less than 48 in. (1220 mm) in height.

#### 7.2.8.6 Materials and Strength.

**7.2.8.6.1** Noncombustible materials shall be used for the construction of all components of fire escape stairs.

**7.2.8.6.2** The authority having jurisdiction shall be permitted to approve any existing fire escape stair that has been shown by load test or other satisfactory evidence to have adequate strength.

#### 7.2.8.7\* Swinging Stairs.

**A.7.2.8.7** Swinging stairs, although superior to fire escape ladders, are generally unsatisfactory, even for emergency use. Although such stairs are permitted by this *Code*, they should not be used where it is reasonably possible to terminate the fire escape stair at the finished ground level.

In cases where the use of a fire escape stair would block a sidewalk or other public way or provide ready access for intruders, the following solution is offered:

1. The discharge can be counterweighted.
2. The unlocked swinging stair can be designed so that a 150 lb (68 kg) weight applied at one quarter of the length of the stair from the pivot point causes the stair to drop into the usable position. See 7.2.8.7.7.

**7.2.8.7.1** A single swinging stair section shall be permitted to terminate fire escape stairs over sidewalks, alleys, or driveways where it is impractical to make the termination with fire escape stairs.

**7.2.8.7.2** Swinging stair sections shall not be located over doors, over the path of travel from any other exit, or in any locations where there are likely to be obstructions.

**7.2.8.7.3** The width of swinging stair sections shall be at least that of the fire escape stairs above.

**7.2.8.7.4** The pitch of swinging stair sections shall not exceed the pitch of the fire escape stairs above.

**7.2.8.7.5** Guards and handrails shall be provided in accordance with 7.2.2.4 and shall be similar in height and construction to those used with the fire escape stairs above. Guards and handrails shall be designed to prevent any possibility of injury to persons where stairs swing downward. The clearance between moving sections and any other portion of the stair system where hands have the potential to be caught shall be not less than 4 in. (100 mm).

**7.2.8.7.6** If the distance from the lowest platform to the finished ground level is not less than 12 ft (3660 mm), an intermediate

balcony not more than 12 ft (3660 mm) from the finished ground level and not less than 7 ft (2135 mm) in the clear underneath shall be provided, with width not less than that of the stairs and length not less than 48 in. (1220 mm).

**7.2.8.7.7** Swinging stairs shall be counterbalanced about a pivot, and cables shall not be used. A weight of 150 lb (68 kg) located one step from the pivot shall not cause the stairs to swing downward, and a weight of 150 lb (68 kg) located one-quarter of the length of the swinging stairs from the pivot shall cause the stairs to swing down.

**7.2.8.7.8** The pivot for swinging stairs shall be of a corrosion-resistant assembly or shall have clearances to prevent sticking due to corrosion.

**7.2.8.7.9\*** Devices shall not be installed to lock a swinging stair section in the up position.

**A.7.2.8.7.9** A latch is desirable for holding swinging stairs down after they have swung to the finished ground level.

#### 7.2.8.8 Intervening Spaces.

**7.2.8.8.1** Where approved by the authority having jurisdiction, fire escape stairs shall be permitted to lead to an adjoining roof that is crossed before continuing downward travel. The direction of travel shall be clearly marked, and walkways with guards and handrails complying with 7.2.2.4 shall be provided.

**7.2.8.8.2** Where approved by the authority having jurisdiction, fire escape stairs shall be permitted to be used in combination with inside or outside stairs complying with 7.2.2, provided that a continuous safe path of travel is maintained.

#### 7.2.9 Fire Escape Ladders.

**7.2.9.1 General.** Fire escape ladders complying with 7.2.9.2 and 7.2.9.3 shall be permitted in the means of egress only where providing one of the following:

- (1) Access to unoccupied roof spaces as permitted in 7.2.8.3.4
- (2) Second means of egress from storage elevators as permitted in Chapter 42
- (3) Means of egress from towers and elevated platforms around machinery or similar spaces subject to occupancy not to exceed three persons who are all capable of using the ladder
- (4) Secondary means of egress from boiler rooms or similar spaces subject to occupancy not to exceed three persons who are all capable of using the ladder
- (5) Access to the finished ground level from the lowest balcony or landing of a fire escape stair for small buildings as permitted in 7.2.8.4 where approved by the authority having jurisdiction

The *Code* does not intend to encourage the use of ladders but intends to provide access to an exit from any regularly occupied area. The *Code* contains provisions for fire escape ladders only because these ladders are sometimes one of the only practical means of moving from one space to another along what might be a path of escape from spaces not normally occupied. The *Code* does specify requirements for ladder construction and installation to ensure structural integrity and ease of use if ladders must be used. The provisions of 7.2.9.1 constitute the minimal recognition given fire escape ladders by this *Code*. Subsection 7.2.11 also addresses alternating tread devices for use under conditions similar to those specified for fire escape ladders.

### 7.2.9.2 Construction and Installation.

**7.2.9.2.1** Fire escape ladders shall comply with ANSI A14.3, *Safety Requirements for Fixed Ladders*, unless one of the following criteria is met:

- (1) Approved existing ladders complying with the edition of this *Code* that was in effect when the ladders were installed shall be permitted.
- (2) Industrial stairs complying with the minimum requirements for fixed stairs of ANSI/ASSE A1264.1, *Safety Requirements for Workplace Walking/Working Surfaces and Their Access; Workplace Floor, Wall and Roof Openings; Stairs and Guardrail Systems*, shall be permitted where fire escape ladders are permitted in accordance with Chapter 40.

Fixed industrial stairs can have dimensional criteria that are comparable to ladders or that are nearly comparable to existing means of egress stairs in accordance with 7.2.2. Paragraph 7.2.9.2.1(2) recognizes that some industrial stairs are safer to use than ladders and permits such stairs to be used at locations where fire escape ladders are permitted in industrial occupancies.

**7.2.9.2.2** Ladders shall be installed with a pitch that exceeds 75 degrees.

**7.2.9.3 Access.** The lowest rung of any ladder shall not be more than 12 in. (305 mm) above the level of the surface beneath it.

### 7.2.10 Slide Escapes.

#### 7.2.10.1 General.

**7.2.10.1.1** A slide escape shall be permitted as a component in a means of egress where permitted in Chapters 11 through 43.

Slide escapes are permitted in means of egress only in high hazard industrial occupancies and existing storage occupancies. See 40.2.2.11 and 42.2.2.10.

Ordinarily, an occupant enters a slide escape through a window or special opening in an exterior wall. From that point on, the slide escape functions as an exit discharge. If the slide escape is entered from within the building, it is considered an exit and must be protected by enclosure as required by 7.1.3.2.

Where provided, slide escapes should be used regularly in practice drills or for normal egress, so that occupants are familiar with their use.

A slide pole of the type historically associated with fire stations is not considered a slide escape.

**7.2.10.1.2** Each slide escape shall be of an approved type.

#### 7.2.10.2 Capacity.

**7.2.10.2.1** Slide escapes, where permitted as a required means of egress, shall be rated at a capacity of 60 persons.

**7.2.10.2.2** Slide escapes shall not constitute more than 25 percent of the required egress capacity from any building or structure or any individual story thereof, unless otherwise provided for industrial occupancies in Chapter 40.

The 25 percent limitation on slide escapes as required means of egress emphasizes that other, more common egress components must comprise the majority of the egress capacity.

### 7.2.11\* Alternating Tread Devices.

**A.7.2.11** Special consideration should be given prior to the application of such devices where children, the elderly, or physically disabled persons use such devices. These devices present obstacles in ascent and descent that differ from those for stairs and ladders.

**7.2.11.1** Alternating tread devices complying with 7.2.11.2 shall be permitted in the means of egress only where providing one of the following:

- (1) Access to unoccupied roof spaces as permitted in 7.2.8.3.4
- (2) Second means of egress from storage elevators as permitted in Chapter 42
- (3) Means of egress from towers and elevated platforms around machinery or similar spaces subject to occupancy not to exceed three persons who are all capable of using the alternating tread device
- (4) Secondary means of egress from boiler rooms or similar spaces subject to occupancy not to exceed three persons who are all capable of using the alternating tread device

**7.2.11.2** Alternating tread devices shall comply with all of the following:

- (1) Handrails shall be provided on both sides of alternating tread devices in accordance with 7.2.2.4.4, except as provided in 7.2.11.3.
- (2) The clear width between handrails shall be not less than 17 in. (430 mm) and not more than 24 in. (610 mm).
- (3) Headroom shall be not less than 6 ft 8 in. (2030 mm).
- (4) The angle of the device shall be between 50 degrees and 68 degrees to horizontal.
- (5) The height of the riser shall not exceed 9½ in. (240 mm).
- (6) Treads shall have a projected tread depth of not less than 5⅓ in. (145 mm), measured in accordance with 7.2.2, with

each tread providing 9 ½ in. (240 mm) of depth, including tread overlap.

- (7) A distance of not less than 6 in. (150 mm) shall be provided between the alternating tread device handrail and any other object.
- (8) The initial tread of the alternating tread device shall begin at the same elevation as the platform, landing, or floor surface.
- (9) The alternating treads shall not be laterally separated by a distance of more than 2 in. (51 mm).
- (10) The occupant load served shall not exceed three.

**7.2.11.3** Handrails of alternating tread devices shall comply with the following:

- (1) The handrail height of alternating tread devices, measured above tread nosings, shall be uniform, not less than 30 in. (760 mm), and not more than 34 in. (865 mm).
- (2) Handrails for alternating tread devices shall be permitted to terminate at a location vertically above the top and bottom risers.
- (3) Handrails for alternating tread devices shall not be required to be continuous between flights or to extend beyond the top or bottom risers.
- (4) Alternating tread device guards, with a top rail that also serves as a handrail, shall have a height of not less than 30 in. (760 mm), and not more than 34 in. (865 mm), measured vertically from the leading edge of the device tread nosing.
- (5) Open guards of alternating tread devices shall have rails such that a sphere 21 in. (535 mm) in diameter is not able to pass through any opening.

As used in the *Code*, an alternating tread device is an intermediate form of climbing implement that is a cross between a ladder and a stair. It consists of a steep succession of half-width treads that alternate from the left side to the right side at intervals of one riser height. A person using the device is forced to place the correct foot on each tread. This alternating tread design, now generally manufactured as a series of treads supported by a central spine, permits stairlike half-treads to be used with ladderlike slopes. The use of such devices, which might be awkward due to unfamiliarity or infrequent use, might be acceptable for some occupancies and locations where the alternative means of changing levels are ladders or ships' ladders, devices that generally have pitches of 50 degrees to 75 degrees. Such pitches are approximately twice those permitted for stairs by the *Code*.

An advantage of alternating tread devices is that one can descend with one's back to the device — unlike a ladder where one can only descend safely while facing the ladder because of the more limited surface area and depth of ladder rungs. A further benefit of the device is that objects can be carried more easily while ascending or descending, because the handrails provide support under the arms, which are left free.

**Exhibit 7.144**

*Alternating tread device. (Courtesy of Lapeyre Stair Inc.)*

The *Code* limits the use of alternating tread devices to those situations where a ladder is acceptable. Exhibit 7.144 shows an alternating tread device.

The provisions of 7.2.11.3 for handrails on alternating tread devices were revised for the 2009 edition of the *Code*. In earlier editions, 7.2.11.2(1) required that the handrails provided on both sides of the alternating tread device be in accordance with the handrail provisions of 7.2.2.4.4. Paragraph 7.2.11.2(1) was revised to permit the handrails to be in accordance with 7.2.11.3. Due to the steepness of the alternating tread device, a handrail height in the range of 30 in. to 34 in. (760 mm to 865 mm) is best suited ergonomically for the majority of users. The 17 in. to 24 in. (430 mm to 610 mm) width between handrails positions the user very near the sides of the device, so that the handrails restrict lateral movement and provide support under the arms. A handrail with height in excess of 34 in. (865 mm) begins to encroach on the user's armpit, and, at some height above 34 in. (865 mm), the user's arm can no longer be extended over the handrail.

### 7.2.12 Areas of Refuge.

Subsection 7.2.12 presents the detailed criteria applicable to an area of refuge. The term *area of refuge* and the related terms *accessible area of refuge* and *accessible means of egress* are defined in 3.3.22, 3.3.22.1, and 3.3.172.1, respectively.

Subsection 7.5.4 requires accessible means of egress in new construction in areas accessible to persons with severe mobility impairment. Because an accessible means of egress must be usable by a person with severe mobility impairment, the

components most commonly used in such means of egress are ramps and areas of refuge. Areas of refuge are extensively used for the upper stories of multistory buildings where it might not be feasible to install ramp systems.

The criteria of 7.2.12 were written to bring the *Code* into substantial agreement with the following: the Americans with Disabilities Act Accessibility Guidelines for Buildings and Facilities (ADAAG); its successor, the ADA and ABA Accessibility Guidelines for Buildings and Facilities (ADA-ABA-AG); and ICC/ANSI A117.1, *American National Standard for Accessible and Usable Buildings and Facilities*. The inclusion in the 2009 edition of the expanded requirements of 7.2.12.1.1 for a two-way communication system, even in a building that is protected throughout by automatic sprinklers, moved the *Code* ahead of ADAAG, ADA-ABA-AG, and ICC/ANSI A117.1 in providing persons with severe mobility impairments with an egress system that approaches that provided to occupants who can use stairs.

### 7.2.12.1 General.

**7.2.12.1.1** An area of refuge used as part of a required accessible means of egress in accordance with 7.5.4; consisting of a story in a building that is protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7; and having an accessible story that is one or more stories above or below a story of exit discharge shall meet the following criteria:

- (1) Each elevator landing shall be provided with a two-way communication system for communication between the elevator landing and the fire command center or a central control point approved by the authority having jurisdiction.
- (2) Directions for the use of the two-way communication system, instructions for summoning assistance via the two-way communication system, and written identification of the location shall be posted adjacent to the two-way communication system.
- (3) The two-way communication system shall include both audible and visible signals.

**7.2.12.1.2** An area of refuge used as part of a required accessible means of egress in accordance with 7.5.4 in other than a building that is protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7 shall meet both of the following criteria:

- (1) The area of refuge shall meet the general requirements of Section 7.1.
- (2) The area of refuge shall meet the requirements of 7.2.12.2 and 7.2.12.3.

The provisions of 7.2.12.1.1 and 7.2.12.1.2 and the definition of *area of refuge* in 3.3.22 are interrelated. Their combined effect is to permit three forms of area of refuge to serve as part of an accessible means of egress, as outlined in paragraphs 1 through 3, which follow:

1. On a floor of a building not protected throughout by an approved, supervised automatic sprinkler system, the area of refuge serving as part of an accessible means of egress must meet the special requirements of 7.2.12.2 and 7.2.12.3, as well as the general requirements of Section 7.1.

2. On a floor of a building protected throughout by an approved, supervised automatic sprinkler system — and involving an occupancy that is not exempt from the minimum two accessible rooms provision of the definition of *area of refuge* — an area of refuge serving as part of an accessible means of egress is exempt from the special requirements of 7.2.12.2 and 7.2.12.3. However, the area of refuge must meet the general requirements of Section 7.1, consist of at least two accessible rooms or spaces separated from each other by smoke-resisting partitions, and meet the criteria of 7.2.12.1.1(1) through (3) related to a two-way communication system. The following occupancies are not exempt from the minimum two accessible rooms provision of the definition of *area of refuge*:

1. Assembly occupancies
2. Educational occupancies
3. Day-care occupancies
4. Health care occupancies (which are exempt from accessible means of egress criteria because of the level of life safety provided by the protect-in-place strategy employed by Chapter 18)
5. Detention and correctional occupancies
6. Residential board and care occupancies
7. Industrial occupancies
8. Storage occupancies

3. On a floor of a building protected throughout by an approved, supervised automatic sprinkler system — and involving an occupancy that is exempt from the minimum two accessible rooms provision of the definition of *area of refuge* — an area of refuge serving as part of an accessible means of egress is exempt from the special requirements of 7.2.12.2 and 7.2.12.3 and is also exempt from having to provide the two accessible rooms or spaces separated from each other by smoke-resisting partitions. However, the area of refuge must meet the general requirements of Section 7.1 and meet the criteria of 7.2.12.1.1(1) through (3) related to a two-way communication system. The following occupancies are exempt from the minimum two accessible rooms provision of the definition of *area of refuge*:

1. Hotels and dormitories (28.2.2.12.2, 29.2.2.12.2)
2. Apartment buildings (30.2.2.12.2, 31.2.2.12.2)
3. Mercantile occupancies (36.2.2.12.2, 37.2.2.12.2)
4. Business occupancies (38.2.2.12.2, 39.2.2.12.2)

### 7.2.12.2 Accessibility.

**7.2.12.2.1** Required portions of an area of refuge shall be accessible from the space they serve by an accessible means of egress.

To help ensure that persons with mobility impairments can access the area of refuge, 7.2.12.2.1 requires such accessibility via

an accessible means of egress. Thus, a person attempting to reach the area of refuge must be provided with either level floor travel or ramp travel, not stairs. Similarly, the door assembly to the area of refuge must provide sufficient clear width, typically the 32 in. (810 mm) minimum specified by 7.2.1.2.3.2, to allow a person in a wheelchair to move through the door opening. See the definition of *accessible means of egress* in 3.3.172.1.

**7.2.12.2.2** Required portions of an area of refuge shall have access to a public way via an exit or an elevator without requiring return to the building spaces through which travel to the area of refuge occurred.

An area of refuge is intended to provide only a temporary point of safety to allow delayed-egress travel from any level. Therefore, an area of refuge cannot be a room or space whose only access to the building spaces is via the room or space through which the user arrived. Such an arrangement might trap a person within the area of refuge, since no egress has been provided other than that which requires travel back through the space where the fire is located. Rather, the area of refuge must provide access to a public way via either an elevator or an exit, such as an enclosed exit stair.

**7.2.12.2.3\*** Where the exit providing egress from an area of refuge to a public way that is in accordance with 7.2.12.2.2 includes stairs, the clear width of landings and stair flights, measured between handrails and at all points below handrail height, shall be not less than 48 in. (1220 mm), unless otherwise permitted by the following:

- (1) The minimum 48 in. (1220 mm) clear width shall not be required where the area of refuge is separated from the remainder of the story by a horizontal exit meeting the requirements of 7.2.4. (See also 7.2.12.3.4.)
- (2) Existing stairs and landings that provide a clear width of not less than 37 in. (940 mm), measured at and below handrail height, shall be permitted.

The Code requires 48 in. (1220 mm) of clear width between handrails on exit stairs that provide the required access from the area of refuge to the exit discharge. The 48 in. (1220 mm) clear width requirement is wider than the minimum 44 in. (1120 mm) stair width required by Table 7.2.2.2.1.2(B), which might provide as little as 35 in. (890 mm) of clear width between handrails. [A 4½ in. (114 mm) encroachment is currently permitted at each side of the stair by 7.2.2.2.1.2(A), Table 7.2.2.2.1.1(b), and 7.3.2.2. Prior to the 2003 edition of the Code, the permitted encroachment was 3½ in. (90 mm).] The extra width is required to facilitate the carrying of persons in wheelchairs, as explained in the first two paragraphs of A.7.2.12.2.3. The minimum 48 in. (1220 mm) stair width is a clear width dimension, measured between handrails. The allowances of 7.2.2.2.1.2(A), Table 7.2.2.2.1.1(b), and 7.3.2.2 that permit handrails to encroach as much as 4½ in. (114 mm) on each side of a stair without considering the reduced clear width do not apply. For a stair with normal handrails to

provide the required 48 in. (1220 mm) clear width, the stair needs to be approximately 57 in. (1445 mm) wide.

Paragraph 7.2.12.2.3(1) exempts areas of refuge created by horizontal exits from the extra-wide stair requirement. Horizontal exits in accordance with 7.2.4 consist of barriers with a minimum 2-hour fire resistance rating. The 2-hour rating increases the time for which the area of refuge can maintain tenable conditions. It is believed that this increase in time allows a slower evacuation on a narrower, typical stair to be effectively accomplished.

For the 2012 edition of the Code, former 7.2.12.2.3(2) was deleted. Previously, it permitted a minimum 37 in. (940 mm) of clear width in new construction under specified conditions. Egress had to be in the descending direction, which is easier than climbing stairs and lifting persons with disabilities. Also, special stair descent devices had to be provided on each floor served by the stair, so that occupied wheelchairs did not need to be carried on stairs. The width exemption is no longer recognized as an acceptable alternative for new construction.

Paragraph 7.2.12.2.3(2) recognizes that areas of refuge might be created in existing buildings with existing 44 in. (1120 mm) stairs that provide only 37 in. (940 mm) of clear width because of the 3½ in. (90 mm) handrail encroachment permitted by earlier editions of the Code. To require the stairs in such buildings to be widened retroactively would create a severe hardship.

**A.7.2.12.2.3** A clear width of not less than 48 in. (1220 mm) is needed for a three-person carry of an occupied wheelchair up or down a stair. This procedure, as well as the more difficult two-person wheelchair carry or roll, requires training and experience. Safer alternative stair descent measures for transporting a person who normally requires a wheelchair, or otherwise cannot use stairs, include emergency stair travel devices designed, constructed, and operated in accordance with ANSI/RESNA ED-1, *Emergency Stair Travel Devices Used by Individuals with Disabilities*. In addition to having such devices available where needed, and having persons trained and experienced in their use, it is important to have people trained and experienced in wheelchair transfer techniques.

In view of the logistical difficulties, as well as the dangers inherent in carrying occupied wheelchairs or otherwise transferring and transporting their occupants on stairs, the preferred means of egress from an area of refuge consists of facilities normally employed for ingress and egress by people using wheelchairs. Foremost among these options are elevators meeting the fire fighters' emergency operations requirements of ASME A17.1/CSA B44, *Safety Code for Elevators and Escalators*.

In editions of the Code through 2012, significant guidance on stair descent devices was provided in A.7.2.12.2.3. The criteria — 23 detailed items in the 2012 edition — served as a de facto product standard, in that the industry that manufactures stair descent devices (currently referred to as emergency stair travel devices) had no recognized product standard at that time. A product standard now exists as detailed in the first paragraph of

A.7.2.12.2.3, and the Code no longer needs to list the features necessary for an emergency stair travel device to be effective and safe. Exhibit 7.145, Exhibit 7.146, and Exhibit 7.147 each show an emergency stair travel device.

7.2.12.2.4\* Where an elevator provides access from an area of refuge to a public way that is in accordance with 7.2.12.2.2, all of the following criteria shall be met:

- (1) The elevator shall be approved for fire fighters' emergency operations as provided in ASME A17.1/CSA B44, *Safety Code for Elevators and Escalators*.

Exhibit 7.145

Exhibit 7.147

Emergency stair travel device in use. (Photo courtesy of Garaventa Lift)

- (2) The power supply shall be protected against interruption from fire occurring within the building but outside the area of refuge.
- (3) The elevator shall be located in a shaft system meeting the requirements for smokeproof enclosures in accordance with 7.2.3, unless otherwise provided in 7.2.12.2.4.1 and 7.2.12.2.4.2.

A.7.2.12.2.4 The use of elevators for egress, especially during an emergency such as a fire, is not an approach to be taken without considerable planning, ongoing effort, and a high degree of understanding by everyone involved with the evacuation of persons with mobility impairments. Due in part to the limited capacity of elevators, as well as to the conflicting demands for elevator use for fire-fighting activities, even elevators in accordance with 7.2.12.2.4 cannot be considered as satisfying any of the Code's requirements for egress capacity, number of means of egress, or travel distance to an exit.

7.2.12.2.4.1 The smokeproof enclosure specified in 7.2.12.2.4(3) shall not be required for areas of refuge that are more than 1000 ft<sup>2</sup> (93 m<sup>2</sup>) and that are created by a horizontal exit meeting the requirements of 7.2.4.

7.2.12.2.4.2 The smokeproof enclosure specified in 7.2.12.2.4(3) shall not be required for elevators complying with 7.2.13.

An elevator used to provide the required access from the area of refuge to the exit discharge must be safe to operate in a building with a fire. The Code requires such an elevator to have the Fire

Fighters' Emergency Operations features required by ASME A17.1/CSA B44, *Safety Code for Elevators and Escalators*. One of these features is elevator recall, whereby the elevator is taken out of service if smoke is detected in the elevator machine room or any elevator lobby the elevator serves. Fire service personnel or other trained persons can put the elevator back into service for manual operation by the trained personnel.

Also, the power supply for the elevator must be protected against interruption caused by fire occurring within the building but outside the area of refuge. The electrical wiring would require enclosure within protecting construction — both for the horizontal runs across any floor and the vertical runs from floor to floor — wherever such wiring is outside the area of refuge. The *Code's* intent is to ensure that, if it is safe to operate an elevator within a portion of the building, a fire in some other area will not adversely affect the power to the elevator. If the fire is in the same area as the elevator, it will not be safe to operate. Therefore, the electrical wiring in the same area as the elevator is not required to be protected.

For an elevator to pass a fire floor safely, its shaft must be kept free of smoke. The elevator must be located in a shaft system meeting the requirements of 7.2.3 for smokeproof enclosures. To achieve such compliance, it will probably be necessary for the elevator landing on each floor to be separated from the remainder of the floor via the creation of an enclosed elevator lobby. The requirement for smokeproof enclosure is a performance-based, rather than prescriptive, requirement for elevator vestibules. See 7.2.3 for additional details on smokeproof enclosures.

Paragraph 7.2.12.2.4.1 exempts the smokeproof enclosure for elevators in areas of refuge where those areas of refuge are more than 1000 ft<sup>2</sup> (93 m<sup>2</sup>) and are created by horizontal exits. Horizontal exits in accordance with 7.2.4 consist of barriers with a minimum 2-hour fire resistance rating. The 2-hour rating increases the time for which the area of refuge can maintain tenable conditions. The minimum area criterion helps to ensure that small amounts of smoke entering the area of refuge do not smoke-log the area, so as to make it unusable.

**7.2.12.2.5** The area of refuge shall be provided with a two-way communication system for communication between the area of refuge and a central control point. The door opening to the stair enclosure or the elevator door and the associated portion of the area of refuge that the stair enclosure door opening or elevator door serves shall be identified by signage. (See 7.2.12.3.5.)

**7.2.12.2.6\*** Instructions for summoning assistance, via the two-way communication system, and written identification of the area of refuge location shall be posted adjacent to the two-way communication system.

**A.7.2.12.2.6** The instructions should include the following:

- (1) Directions to find other means of egress
- (2) Advice that persons able to use exit stairs do so as soon as possible, unless they are assisting others

- (3) Information on planned availability of assistance in the use of stairs or supervised operation of elevators and how to summon such assistance
- (4) Directions for use of the emergency communications system

To facilitate an adequate degree of understanding of the use of areas of refuge and of the associated assisted egress procedures, information should be provided to those using the facilities. The exact content of the information, its organization (e.g., as a set of instructions), and its format (e.g., either posted instructions in the area of refuge or information otherwise transmitted to facility users) should be determined on a case-by-case basis. The information should be tailored to the specific facility, its emergency action plan, the intended audience, and the intended presentation format. Suggested information content addressing two situations follows.

*Refuge with Elevator Use.* An area of refuge provided in the elevator lobby serves as a staging area for persons unable to use stairs and needing assistance for their evacuation during an emergency. The elevator(s) will be taken out of automatic service and operated by emergency service personnel. Persons unable to evacuate down the exit stairs without assistance and needing transportation by elevator should make certain the elevator lobby doors are closed while they wait in the elevator lobby for assistance. The two-way communication system should be used if there is a delay of more than several minutes in the arrival of an elevator that will provide transportation to the level of exit discharge. Alternatively, another refuge area, and assistance with evacuation, is available in the designated exit stair.

*Refuge with Stair Use.* An area of refuge within the designated exit stair serves as a staging area for persons needing assistance for their evacuation during an emergency. Persons unable to use the stairs unassisted, or who wish to move down the stairs at a slower pace, should wait on the stair landing. The two-way communication system should be used if assistance is needed.

The provisions of 7.2.12.2.5 for a two-way communication system are reached via the road map provided in 7.2.12.1.2, meaning that the building in question is not protected throughout by an approved, supervised automatic sprinkler system. For sprinklered buildings, the two-way communication provisions of 7.2.12.1.1 apply. In a nonsprinklered building, either an elevator or a stair is provided as access from the area of refuge to a public way; however, persons with mobility impairments might not be able to use the elevator or stair without assistance. For example, an elevator might have been called out of service because smoke was detected in one of the elevator lobbies serving that elevator or in the elevator machine room. A person in a wheelchair would need to call for help. Therefore, the *Code* requires a two-way communication system between the area of refuge and a central control point; the communication system is used to summon assistance. Additionally, signage and instructions are required to help complete the package of features for use by persons with disabilities.

**Figure A.7.2.12.3.1** Exit Stair Used as an Area of Refuge.

### 7.2.12.3 Details.

**7.2.12.3.1\*** Each area of refuge shall be sized to accommodate one wheelchair space of 30 in. × 48 in. (760 mm × 1220 mm) for every 200 occupants, or portion thereof, based on the occupant load served by the area of refuge. Such wheelchair spaces shall maintain the width of a means of egress to not less than that required for the occupant load served and to not less than 36 in. (915 mm).

**A.7.2.12.3.1** Figure A.7.2.12.3.1 illustrates the application of the minimum space requirement to an area of refuge located within an exit stair enclosure. Note that each of the two required spaces is sufficient to allow the parking of a standard wheelchair. Preferably, such spaces should be provided adjacent to each other in a location where the presence of people taking temporary shelter in an area of refuge will be immediately apparent to rescue personnel and other evacuees.

**7.2.12.3.2\*** For any area of refuge that does not exceed 1000 ft<sup>2</sup> (93 m<sup>2</sup>), it shall be demonstrated by calculation or test that tenable conditions are maintained within the area of refuge for a period of 15 minutes when the exposing space on the other side of the separation creating the area of refuge is subjected to the maximum expected fire conditions.

Areas of refuge of less than 1000 ft<sup>2</sup> (93 m<sup>2</sup>) might be more easily affected than larger areas by the products of combustion from a fire in the area on the other side of the separating barrier. Thus, tenability must be demonstrated by calculation or test. An area of refuge within an exit stair enclosure, as shown in Figure A.7.2.12.3.1, would be required to demonstrate tenability. However, an area of refuge consisting of half of a 2200 ft<sup>2</sup> (205 m<sup>2</sup>) floor would not be required to do so.

**A.7.2.12.3.2** The method of meeting the tenability performance criteria required of an area of refuge of less than 1000 ft<sup>2</sup> (93 m<sup>2</sup>) can involve controlling the exposing fire (e.g., via automatic sprinkler protection), installing smoke-resisting doors in the smoke-resisting barriers (see NFPA 105, *Standard for Smoke Door Assemblies and Other Opening Protectives*), providing smoke control to prevent or limit smoke migration through cracks or other leakage paths (see NFPA 92, *Standard for Smoke Control Systems*), or providing other means or a combination of these means.

Calculations, if used, need to be based on established engineering relationships and equations. Such calculational procedures are described in NFPA 92 and the *SFPE Handbook of Fire Protection Engineering*. Tenable conditions are those that maintain the temperature of any smoke in the area of refuge at less than 200°F (93°C) if the smoke is more than 60 in. (1525 mm) above the floor, and at less than 120°F (49°C) if the smoke descends below the 60 in. (1525 mm) level in the area of refuge. Also, if the smoke descends below the 60 in. (1525 mm) level, tenable conditions require not less than 16 percent oxygen and not more than 30,000 ppm/min exposure to carbon monoxide. The exposing conditions used in the calculations should be in accordance with the following:

- (1) The exposing space is sprinkler protected, and the following conditions also exist:
  - (a) The temperature of the exposing smoke is 200°F (93°C).
  - (b) The smoke layer extends to the floor.
  - (c) The oxygen content is 16 percent.
  - (d) The carbon monoxide concentration is 2000 ppm (0.2 percent).
- (2) The exposing space is a nonsprinklered corridor finished with Class A interior wall and ceiling finish, and the following conditions also exist:
  - (a) The temperature of the exposing smoke is 600°F (316°C).
  - (b) The smoke layer extends to a level 24 in. (610 mm) above the floor.
  - (c) The oxygen content is 3 percent.
  - (d) The carbon monoxide concentration is 50,000 ppm (5 percent).
- (3) The exposing space is either not a corridor or, if a corridor, the corridor is not finished with a Class A interior wall and ceiling finish, and the following conditions also exist:
  - (a) The temperature of the exposing smoke is 1500°F (815°C).
  - (b) The smoke layer extends to a level 24 in. (610 mm) above the floor.
  - (c) The oxygen content is 3 percent.
  - (d) The carbon monoxide concentration is 50,000 ppm (5 percent).

**7.2.12.3.3** Access to any designated wheelchair space in an area of refuge shall not pass through more than one adjoining wheelchair space.

**7.2.12.3.4\*** Each area of refuge shall be separated from the remainder of the story by a barrier having a minimum 1-hour fire resistance rating, unless one of the following criteria applies:

- (1) A greater rating is required in other provisions of this Code.
- (2) The barrier is an existing barrier with a minimum 30-minute fire resistance rating.

**A.7.2.12.3.4** Requirements for fire resistance ratings in excess of 1 hour, fire protection ratings in excess of 20 minutes, and

prohibitions on duct penetrations appear in other *Code* sections. For example, if the barrier creating the area of refuge is also part of an exit stair enclosure that connects two or more stories, or is a horizontal exit, a minimum 2-hour fire resistance rating for the barrier and a minimum 1½-hour fire protection rating for opening protectives, such as doors, would be required for most occupancies.

For further information on door openings in smoke-resisting barriers, see NFPA 105, *Standard for Smoke Door Assemblies and Other Opening Protectives*.

Generally, by providing one barrier that subdivides a floor area, two areas of refuge can be created. This subdivision method and the possibility of creating areas of refuge within compartmented elevator lobbies or on enlarged stair landings of exit stair enclosures make less onerous any requirement for a story to have more than one accessible means of egress.

As explained in the commentary following 7.2.12.1.2, these requirements for fire resistance-rated separating barriers and fire protection-rated separating door assemblies are not required for areas of refuge in buildings protected throughout by approved, supervised automatic sprinkler systems per 7.2.12.1.2.

Exhibit 7.148 illustrates an area of refuge in a new sprinklered business occupancy. The area of refuge is used to meet the requirements for accessible means of egress, because persons with severe mobility impairment are able to access the floor via the elevator. Paragraph 38.2.2.12.2 exempts the floor that serves as an area of refuge from having to provide two rooms or spaces separated from each other by smoke-resistant partitions if the new business occupancy building is protected throughout by an approved, supervised automatic sprinkler system. The open floor area depicted therefore meets the requirements for an area of refuge, provided that the two-way communication system (as noted by the accessible phone symbol) is installed at the elevator landing in accordance with

Area of refuge in new sprinklered business occupancy.

**Exhibit 7.149**

Area of refuge in new sprinklered industrial occupancy.

7.2.12.1.1. The accessible phone symbol is detailed in NFPA 170, *Standard for Fire Safety and Emergency Symbols*.<sup>19</sup>

Exhibit 7.149 depicts an area of refuge in a new sprinklered industrial occupancy. The area of refuge is used to meet the requirements for accessible means of egress, because persons with severe mobility impairment are able to access the floor via the elevator. Industrial occupancies are not exempt from the area of refuge provision for two rooms or spaces separated from each other by smoke-resistant partitions. Thus, in this building, which is protected throughout by an approved, supervised automatic sprinkler system, a second room is provided on this floor. Note that the second room can be anywhere on the floor; it doesn't have to be adjacent to or in an exit stair enclosure. Although the separating barriers and door assembly are not required to be fire rated, they must be smoke resistant as addressed in the definition of *area of refuge* in 3.3.22. With this arrangement, the floor meets the requirements for an area of refuge, provided that the two-way communication system (as noted by the NFPA 170 accessible phone symbol) is installed at the elevator landing in accordance with 7.2.12.1.1.

Exhibit 7.150 depicts areas of refuge in nonsprinklered new construction. The area of refuge is used to meet the requirements for accessible means of egress, because persons with severe mobility impairment are able to access the floor via the elevator. The barrier dividing the floor into two areas of refuge has a 1-hour fire resistance rating; the door assembly has a 20-minute fire protection rating. Each area is more than 1000 ft<sup>2</sup> (93 m<sup>2</sup>), and no tenability calculations are required. In the area of refuge at the left, the elevator is provided with the special features detailed in 7.2.12.2.4 and serves as access to the public way; the stair in this compartment is permitted to have the usual 44 in. (1120 mm) width. In the area of refuge at the right, the stair serves as access to the public way and must be approximately 57 in. (1455 mm) wide to provide the required 48 in. (1220 mm) clear width between handrails. Two-way communication capability (as noted by the NFPA 170 accessible phone symbol),

Exhibit 7.150

Areas of refuge in nonsprinklered new construction.

Exhibit 7.152

Two areas of refuge — one using space within an exit stair enclosure — in nonsprinklered new construction.

Exhibit 7.151

Areas of refuge created by horizontal exit in nonsprinklered new construction.

signage, and posted instructions are required in each area of refuge in accordance with 7.2.12.2.5 and 7.2.12.2.6.

Exhibit 7.151 depicts areas of refuge created by a horizontal exit in nonsprinklered new construction. The area of refuge is used to meet the requirements for accessible means of egress, because persons with severe mobility impairment are able to access the floor via the elevator. The barrier dividing the floor into two areas of refuge is a horizontal exit with a 2-hour fire resistance rating; the door assemblies have a 1½-hour fire protection rating. Each area is more than 1000 ft<sup>2</sup> (93 m<sup>2</sup>), so no tenability calculations are required. Because the separating barrier is a horizontal exit, the stairs are permitted to be typical 44 in. (1120 mm) width stairs that might provide only 35 in. (890 mm) of clear width between handrails, and the elevator is not required to have the special features detailed in 7.2.12.2.4. Two-way communication capability (as noted by the NFPA 170 accessible phone symbol), signage, and posted instructions are required in each area of refuge in accordance with 7.2.12.2.5 and 7.2.12.2.6.

Exhibit 7.152 depicts an area of refuge that uses space within the exit stair enclosure in nonsprinklered new construction. The area of refuge is used to meet the requirements for accessible means of egress, because persons with severe mobility impairment are able to access the floor via the elevator. The exit stair enclosure walls at the right of the exhibit provide the barrier that creates two areas of refuge on the floor. The area of refuge within that exit stair enclosure at the right of the exhibit is less than 1000 ft<sup>2</sup> (93 m<sup>2</sup>), and tenability must be demonstrated. The remainder of the floor serves as the second area of refuge; it is larger than 1000 ft<sup>2</sup> (93 m<sup>2</sup>), and no tenability calculation is required. Stairs provide access from each area of refuge to a public way, as the elevator does not have the special features detailed in 7.2.12.2.4. The stairs must be approximately 57 in. (1455 mm) wide to provide the required 48 in. (1220 mm) clear width between handrails. Two-way communication capability (as noted by the NFPA 170 accessible phone symbol), signage, and posted instructions are required in each area of refuge in accordance with 7.2.12.2.5 and 7.2.12.2.6.

**7.2.12.3.4.1** New fire door assemblies serving an area of refuge shall be smoke leakage-rated in accordance with 8.2.2.4.

**7.2.12.3.4.2** The barriers specified in 7.2.12.3.4, and any openings in them, shall minimize air leakage and resist the passage of smoke.

**7.2.12.3.4.3** Door assemblies in the barriers specified in 7.2.12.3.4 shall have not less than a 20-minute fire protection rating, unless a greater rating is required in other provisions of this Code, and shall be either self-closing or automatic-closing in accordance with 7.2.1.8.

**7.2.12.3.4.4** Ducts shall be permitted to penetrate the barrier specified in 7.2.12.3.4, unless prohibited in other provisions of this Code, and shall be provided with smoke-actuated dampers or other approved means to resist the transfer of smoke into the area of refuge.

**7.2.12.3.5** Each area of refuge shall be identified by a sign that reads as the follows:

#### AREA OF REFUGE

**Exhibit 7.153** shows a sign at the door leading to an area of refuge located on an enlarged stair landing within an exit stair enclosure. The sign does not mark the area of refuge itself but the location of the area of refuge, which cannot be seen with the exit stair enclosure door in its closed position. The sign uses the terminology *area of rescue assistance*, rather than *area of refuge*, as the building emergency plan and occupant training use the term *area of rescue assistance*.

**7.2.12.3.5.1** The sign required by **7.2.12.3.5** shall conform to the requirements of ICC/ANSI A117.1, *American National Standard for Accessible and Usable Buildings and Facilities*, for such signage and shall display the international symbol of accessibility. Signs also shall be located as follows:

- (1) At each door opening providing access to the area of refuge
- (2) At all exits not providing an accessible means of egress, as defined in **3.3.172.1**
- (3) Where necessary to indicate clearly the direction to an area of refuge

**7.2.12.3.5.2** Signs required by **7.2.12.3.5** shall be illuminated as required for special signs in accordance with **7.10.8.1**.

**7.2.12.3.6** Tactile signage complying with ICC/ANSI A117.1, *American National Standard for Accessible and Usable Buildings and Facilities*,

**Exhibit 7.153**

Sign showing location of area of refuge. (Courtesy of Jake Pauls)

and *Facilities*, shall be located at each door opening to an area of refuge.

#### 7.2.13 Elevators in Towers.

The title of **7.2.13** was revised for the 2015 edition of the *Code* to add the words “in towers” because its provisions are limited to use in towers as detailed in **7.2.13.1**. Further, the tower is not permitted to be used by the general public as specified in **7.2.13.1(7)**. An example of a tower that might make use of the provisions of **7.2.13** is an air traffic control tower at an airport. A high-rise office building with a low-rise pavilion is not subject to use of the provisions of **7.2.13**, even though the high-rise portion of the building might be referred to as a *tower*.

See **Section 7.14** for elevators that can be used by occupants for evacuation prior to the time that elevators are called out of service due to conditions that might be detrimental to safe elevator use.

**7.2.13.1\* General.** An elevator complying with the requirements of **Section 9.4** and **7.2.13** shall be permitted to be used as a second means of egress from a tower, as defined in **3.3.281**, provided that all of the following criteria are met:

- (1) The tower and any attached structure shall be protected throughout by an approved, supervised automatic sprinkler system in accordance with **Section 9.7**.
- (2) The tower shall be subject to occupancy not to exceed 90 persons.
- (3) Primary egress discharges shall be directly to the outside.
- (4) No high hazard content areas shall exist in the tower or attached structure.
- (5) One hundred percent of the egress capacity shall be provided independent of the elevators.
- (6) An evacuation plan that specifically includes the elevator shall be implemented, and staff personnel shall be trained in operations and procedures for elevator emergency use in normal operating mode prior to fire fighter recall.
- (7) The tower shall not be used by the general public.

**A.7.2.13.1** It is the intent of **7.2.13.1** that elevators serving as a means of egress serve only independent towers or the tower portion of any integral structure. For elevators that are used as a component in the means of egress, the elevator lobbies, elevator shaft, and machine room need to be protected from the effects of fire.

**Subsections 7.2.1 through 7.2.12** are formatted to describe one of 12 potential components of means of egress, such as door assemblies (**7.2.1**), stairs (**7.2.2**), ramps (**7.2.5**), or slide escapes (**7.2.10**). The occupancy chapters specify whether each of these components is permitted to be used within the required means of egress. The recognition of these components by the occupancy chapters ranges from “permitted by all” for door assemblies to “very limited use” for slide escapes in high hazard industrial and existing storage occupancies. However, in each case, it is the occupancy chapter that determines the

applicability of any of the 12 egress components. Subsection 7.2.13 is formatted differently. It limits the use of elevators within means of egress to serving only as a secondary, not primary, means of egress from towers.

The recognition of elevators for emergency egress is limited to towers not used by the general public [see 7.2.13.1(7)]. The occupants will generally be employees, who are familiar with the structure because of repeated occupancy. Although members of the public have likely been taught not to use elevators during fire or similar emergency, the tower's employees can be trained to use elevators effectively for egress.

Note that 7.2.13.1(1) requires the tower to be sprinklered to keep conditions tenable while the elevator is being used. Paragraph 7.2.13.1(2) limits occupancy in the tower to a maximum of 90 persons. Paragraph 7.2.13.1(5) requires that 100 percent of the egress capacity be provided without considering the capacity provided by the elevator. Thus, the elevator helps to satisfy the requirement for a redundant, second egress route, but the primary route (typically a stair) must be sized to accommodate the entire occupant load.

### 7.2.13.2 Elevator Evacuation System Capacity.

**7.2.13.2.1** The elevator car shall have a capacity of not less than eight persons.

**7.2.13.2.2** The elevator lobby shall have a capacity of not less than 50 percent of the occupant load of the area served by the lobby. The capacity shall be calculated based on 3 ft<sup>2</sup> (0.28 m<sup>2</sup>) per person and shall also include one wheelchair space of 30 in. × 48 in. (760 mm × 1220 mm) for every 50 persons, or portion thereof, of the total occupant load served by that lobby.

**7.2.13.3 Elevator Lobby.** Every floor served by the elevator shall have an elevator lobby. Barriers forming the elevator lobby shall have a minimum 1-hour fire resistance rating and shall be arranged as a smoke barrier in accordance with Section 8.5.

**7.2.13.4 Elevator Lobby Door Assemblies.** Elevator lobby door assemblies shall have a minimum 1-hour fire protection rating. The transmitted temperature end point shall not exceed 450°F Δ (250°C Δ) above ambient at the end of 30 minutes of the fire exposure specified in the test method referenced in 8.3.3.2. Elevator lobby door leaves shall be self-closing or automatic-closing in accordance with 7.2.1.8.

**7.2.13.5 Door Leaf Activation.** The elevator lobby door leaves shall close in response to a signal from a smoke detector located directly outside the elevator lobby adjacent to or on each door opening. Elevator lobby door leaves shall be permitted to close in response to a signal from the building fire alarm system. Where one elevator lobby door leaf closes by means of a smoke detector or a signal from the building fire alarm system, all elevator lobby door leaves serving that elevator evacuation system shall close.

**7.2.13.6\* Water Protection.** Building elements shall be used to restrict water exposure of elevator equipment.

**A.7.2.13.6** One or more of the following approaches can be used to restrict exposure of elevator equipment to water:

- (1) A combination of sealed elevator lobby doors, sloped floors, floor drains, and sealed elevator shaft walls is used.
- (2) The elevator is mounted on the building exterior that normally operates in the elements, and seals are used on the elevator lobby doors.
- (3) The elevator shaft is separated from the building at each floor by an exterior elevator lobby designed to prevent water entry into the elevator shaft.

Information gained from ongoing research concerning waterflow and elevators could lead to the development of water-resistant or water-protected elevator equipment specifically for fire applications. Such equipment should be used only with the building elements (e.g., sealed elevator lobby doors, sloped floors, floor drains) for which it is developed. Further information is available from the NIST publication, *Feasibility of Fire Evacuation by Elevators at FAA Control Towers*.

**7.2.13.7\* Power and Control Wiring.** Elevator equipment, elevator communications, elevator machine room cooling, and elevator controller cooling shall be supplied by both normal and standby power. Wiring for power and control shall be located and properly protected to ensure a minimum 1 hour of operation in the event of a fire.

**A.7.2.13.7** Cooling equipment dedicated to the elevator machine room can be used to minimize requirements for standby power.

**7.2.13.8\* Communications.** Two-way communication systems shall be provided between elevator lobbies and a central control point and between elevator cars and a central control point. Communications wiring shall be protected to ensure a minimum 1 hour of operation in the event of fire.

**A.7.2.13.8** Communication between elevator lobbies and a central control point can be by telephone or intercom. Auditory alarms should be designed so that they do not interfere with people talking on communications systems.

**7.2.13.9\* Elevator Operation.** Elevators shall be provided with fire fighters' emergency operations in accordance with ASME A17.1/CSA B44, *Safety Code for Elevators and Escalators*.

**A.7.2.13.9** Smoke detection in the elevator lobby will result in a Phase I recall of the elevators. The elevators will then be automatically taken out of normal service and will be available to be operated by emergency service personnel.

**7.2.13.10 Maintenance.** Where an elevator lobby is served by only one elevator car, the elevator evacuation system shall have a program of scheduled maintenance during times of building shutdown or low building activity. Repairs shall be performed within 24 hours of breakdown.

**7.2.13.11 Earthquake Protection.** Elevators shall have the capability of orderly shutdowns during earthquakes at locations

where such shutdowns are an option of ASME A17.1/CSA B44, *Safety Code for Elevators and Escalators*.

**7.2.13.12 Signage.** Signage shall comply with 7.10.8.4.

## 7.3 Capacity of Means of Egress

### 7.3.1 Occupant Load.

#### 7.3.1.1 Sufficient Capacity.

**7.3.1.1.1** The total capacity of the means of egress for any story, balcony, tier, or other occupied space shall be sufficient for the occupant load thereof.

**7.3.1.1.2** For other than existing means of egress, where more than one means of egress is required, the means of egress shall be of such width and capacity that the loss of any one means of egress leaves available not less than 50 percent of the required capacity.

It is a basic concept of the *Code* that the means of egress system be sized to accommodate all people occupying a building. Sizing is accomplished via a code-specified method of matching the occupant load of a floor against the calculated egress capacity of the egress components serving the floor. The sizing criteria do not ensure that all occupants can leave immediately, but they do provide for sufficient quick movement without unacceptable queuing; that is, occupants might have to wait in line to pass through an exit stair enclosure door assembly to begin moving down the stairs, especially where occupants of upper floors who have already entered the stair enclosure are simultaneously using the stairs for egress travel in the downward direction.

The geometry of a building, its occupancy and related occupant load, and the travel distance to exits dictate, in large measure, the location of exits, the number of exits, and the capacity of exits and access thereto. As a consequence, the exits themselves influence the plan and layout of the entire means of egress system. The number of people that the means of egress system can accommodate is determined not solely by the capacity (i.e., width) of the exits but also by the number of persons each component within the exit access and exit discharge can accommodate. Very wide corridors that lead to very wide exit stair enclosure door assemblies that then lead to much more narrow stairs provide a system comparable to average-width corridors that lead to average-width exit stair enclosure door assemblies that then lead to average-width stairs. A means of egress system is only as good as its most constricting component.

The number of people or occupant load for which the means of egress system must provide egress capacity is calculated or otherwise determined. The occupant load is to reflect the maximum number of people anticipated to occupy the building rooms or spaces at any given time and under all probable situations. The occupant load must not be based only on normal occupancy.

The provision of 7.3.1.1.2 has the effect of requiring that new egress systems employing two means of egress be balanced in size, so that each egress route accommodates at least half of the occupant load of the floor. It also has the effect of requiring that new egress systems employing more than two means of egress be sized so that no one egress route is credited with accommodating more than half of the occupant load of the floor. The requirement is aimed at preventing a situation where the loss of any one egress route reduces the remaining egress capacity to less than half of that needed to accommodate the occupant load of the floor. Application of the provision of 7.3.1.1.2 is demonstrated in the examples that follow.

#### Example 1

The occupant load of a floor in a new building is 350 persons. Two means of egress are provided. Egress route 1 is of sufficient width to accommodate 200 persons, and egress route 2 accommodates 150. The two egress routes, together, exactly accommodate the 350-person occupant load of the floor. If fire or similar emergency were to render egress route 1 unusable, the performance-based criterion of 7.3.1.1.2 would not be met, as less than half the required egress capacity remains usable [i.e.,  $150 < 350/2$ ]. The designer chooses to resize both egress routes so that each accommodates 175 persons. Following the redesign, the arrangement is again evaluated against the criterion of 7.3.1.1.2. The loss of any one of the two egress routes leaves available not less than 50 percent of the required egress capacity of the floor as required by 7.3.1.1.2.

#### Example 2

The occupant load of a floor in a new building is 350 persons. Two means of egress are provided. Egress route 1 is of sufficient width to accommodate 200 persons, and egress route 2 accommodates 175. The two egress routes, together, accommodate 375 persons, which is 25 persons more than required to be accommodated for the 350-person occupant load of the floor. If fire or similar emergency were to render egress route 1 unusable, the performance-based criterion of 7.3.1.1.2 would be met, as at least half the required egress capacity (i.e.,  $350/2 = 175$ ) remains usable as required by 7.3.1.1.2.

#### Example 3

The occupant load of a floor in a new building is 640 persons. Three means of egress are provided in accordance with 7.4.1.2. Egress route 1 is of sufficient width to accommodate 340 persons, and egress route 2 and egress route 3 each accommodate 150 persons. The three egress routes, together, exactly accommodate the 640-person occupant load of the floor. If a fire or similar emergency were to render egress route 1 unusable, the performance-based criterion of 7.3.1.1.2 would not be met, as less than half the required egress capacity remains usable via the combination of egress route 2 and egress route 3

[i.e.,  $150 + 150 = 300$ ;  $300 < 640/2$ ]. The designer chooses to resize all three egress routes so that egress route 1 accommodates 320 persons and egress route 2 and egress route 3 each accommodate 160 persons. Following the redesign, the arrangement is again evaluated against the criterion of 7.3.1.1.2. The loss of egress route 1 leaves available not less than 50 percent of the required egress capacity of the floor as required by 7.3.1.1.2.

**7.3.1.2\* Occupant Load Factor.** The occupant load in any building or portion thereof shall be not less than the number of

persons determined by dividing the floor area assigned to that use by the occupant load factor for that use as specified in Table 7.3.1.2, Figure 7.3.1.2(a), and Figure 7.3.1.2(b). Where both gross and net area figures are given for the same occupancy, calculations shall be made by applying the gross area figure to the gross area of the portion of the building devoted to the use for which the gross area figure is specified and by applying the net area figure to the net area of the portion of the building devoted to the use for which the net area figure is specified.

**Table 7.3.1.2 Occupant Load Factor**

In mercantile occupancies	300	27.9
In other than storage and mercantile occupancies	500	46.5

NA: Not applicable. The occupant load is the maximum probable number of occupants present at any time.

<sup>a</sup>All factors are expressed in gross area unless marked “net.”

<sup>b</sup>For the purpose of determining occupant load in mercantile occupancies where, due to differences in the finished ground level of streets on different sides, two or more floors directly accessible from streets (not including alleys or similar back streets) exist, each such floor is permitted to be considered a street floor. The occupant load factor is one person for each 40 ft<sup>2</sup> (3.7 m<sup>2</sup>) of gross floor area of sales space.

<sup>c</sup>For the purpose of determining occupant load in mercantile occupancies with no street floor, as defined in 3.3.271, but with access directly from the street by stairs or escalators, the floor at the point of entrance to the mercantile occupancy is considered the street floor.

<sup>d</sup>For any food court or other assembly use areas located in the mall that are not included as a portion of the gross leasable area of the mall building, the occupant load is calculated based on the occupant load factor for that use as specified in Table 7.3.1.2. The remaining mall area is not required to be assigned an occupant load.

<sup>e</sup>The portions of the mall that are considered a pedestrian way and not used as gross leasable area are not required to be assessed an occupant load based on Table 7.3.1.2. However, means of egress from a mall pedestrian way are required to be provided for an occupant load determined by dividing the gross leasable area of the mall building (not including anchor stores) by the appropriate lowest whole number occupant load factor from Figure 7.3.1.2(a) or Figure 7.3.1.2(b).

Each individual tenant space is required to have means of egress to the outside or to the mall based on occupant loads calculated by using the appropriate occupant load factor from Table 7.3.1.2.

Each individual anchor store is required to have means of egress independent of the mall.

<sup>f</sup>See A.7.3.1.2.

Figure 7.3.1.2(a) Mall Building Occupant Load Factors (U.S. Customary Units).

Figure 7.3.1.2(b) Mall Building Occupant Load Factors (SI Units).

**A.7.3.1.2** The normal occupant load is not necessarily a suitable criterion, because the greatest hazard can occur when an unusually large crowd is present, which is a condition often difficult for authorities having jurisdiction to control by regulatory measures. The principle of this *Code* is to provide means of egress for the maximum probable number of occupants, rather than to attempt to limit occupants to a number commensurate with available means of egress. However, limits of occupancy are specified in certain special cases for other reasons.

Suggested occupant load factors for components of large airport terminal buildings are given in [Table A.7.3.1.2](#). However, the authority having jurisdiction might elect to use different occupant load factors, provided that egress requirements are satisfied.

**Table A.7.3.1.2 Airport Terminal Occupant Load Factors**

Airport Terminal Area	ft <sup>2</sup> (gross)	m <sup>2</sup> (gross)
Concourse	100	9.3
Waiting areas	15	1.4
Baggage claim	20	1.9
Baggage handling	300	27.9

The figure used in determining the occupancy load for mall shopping centers of varying sizes was arrived at empirically by surveying over 270 mall shopping centers, by studying mercantile occupancy parking requirements, and by observing the number of occupants per vehicle during peak seasons.

These studies show that, with an increase in shopping center size, there is a decrease in the number of occupants per square foot of gross leasable area.

These studies show that, with an increase in shopping center size, there is a decrease in the number of occupants per square foot of gross leasable area.

This phenomenon is explained when one considers that, above a certain shopping center gross leasable area [approximately 600,000 ft<sup>2</sup> (56,000 m<sup>2</sup>)], there exists a multiplicity of the same types of stores. The purpose of duplicate types of stores is to increase the choices available to a customer for any given type of merchandise. Therefore, when shopping center size increases, the occupant load increases as well, but at a declining rate. In using [Figure 7.3.1.2\(a\)](#) or [Figure 7.3.1.2\(b\)](#), the occupant load factor is applied only to the gross leasable area that uses the mall as a means of egress.

The value for concentrated business use is intended to address business use spaces with a higher density of occupants than would normally be expected in a general business occupancy. Where furnishings and floor layouts are arranged to maximize the number of occupants in the space, the value for

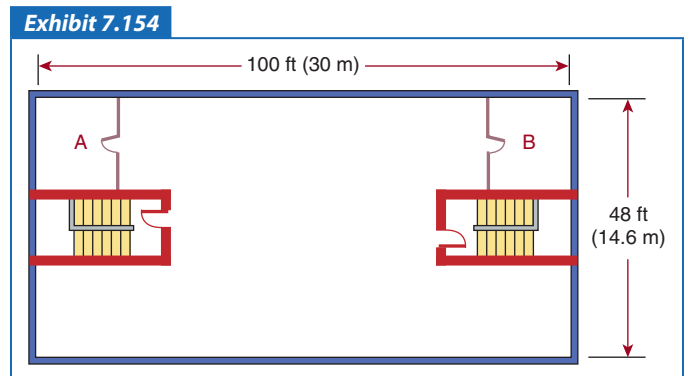

concentrated business use should be applied. Examples of concentrated business use areas are call centers, trading floors, and data processing centers.

Occupant load is determined by the nature of the use of a building or space and the amount of space available for that use. Since different generic uses are characterized by different occupant densities, [Table 7.3.1.2](#) has established occupant load factors for each use. The first column of the table is deliberately headed “use” rather than “occupancy,” because the use of an area might differ from its occupancy classification. For example, a meeting room for fewer than 50 people in an office building is not an assembly occupancy; it is part of the larger business occupancy [see [6.1.14.1.3\(2\)](#)], but its occupant load is based on an assembly use. The same concept applies to a classroom in a university, which, although classified as a business occupancy, has an occupant load based on educational use (for traditional classroom style) or assembly use (for lecture style with theater-type seating).

The occupant load factor, as a density factor, assumes the presence of at least one person for each specified unit of area. Note that some values are for net area, while others are based on gross area. The gross area figure applies to the building as a whole (the area within the confining perimeter walls of the building, including areas that are occupied by shafts and other elements that people do not occupy); the net area figure applies to actual occupied spaces, such as classroom spaces, and does not include the corridors, the area occupied by walls, or other unoccupied areas.

Cases of mixed use might exist where, for example, an assembly use space having an occupant load based on net floor area might be located in a building that is primarily a business occupancy, a classification for which the occupant load is based on gross area. In such instances, the net area calculations should be performed for those specific areas that use occupant load factors based on net area; the remaining floor area can then be used to calculate the occupant load for the uses employing gross floor area. This is illustrated in [Exhibit 7.154](#).

In [Exhibit 7.154](#), the majority of the 4800 ft<sup>2</sup> (446 m<sup>2</sup>) gross floor area [i.e., 100 ft × 48 ft (30 m × 14.6 m)] is used for business

*Floor area for occupant load considerations.*

purposes and is occupied by desks, chairs, file cabinets, office machines, and associated office personnel. Rooms A and B are conference rooms with tables and chairs used on a regular basis, primarily by company personnel from other floors in the building. These rooms can be expected to be occupied simultaneously with the remainder of the floor. Each conference room provides 320 ft<sup>2</sup> (30 m<sup>2</sup>) of net usable area. Because neither conference room can accommodate 50 or more persons, an assembly occupancy is not created. Rather, the floor is a business occupancy with some incidental assembly use [again, see 6.1.14.1.3(2)].

Because occupant load is calculated based on use of the space (not occupancy classification), the occupant load of the floor shown in Exhibit 7.154 is calculated using occupant load factors for both an assembly use, which is based on net area, and a business use, which is based on gross area. The occupant load of the assembly use spaces (conference rooms A and B) is calculated first. Using Table 7.3.1.2, a net area factor of 15 ft<sup>2</sup> (1.4 m<sup>2</sup>) per person for assembly, “less concentrated use,” is chosen. [Note that the concept of “less concentrated use” refers to the possible concentration of occupants where, because of the presence of tables and chairs, there are fewer occupants than would be possible without the tables and chairs, which is an example of “concentrated use.”] The two conference rooms must be assumed to have a combined occupant load of at least 43 persons, according to the following calculation:

$$\frac{640 \text{ ft}^2}{15 \text{ ft}^2 \text{ per person}} = 43 \text{ persons}$$

$$\left[ \frac{60 \text{ m}^2}{1.4 \text{ m}^2 \text{ per person}} = 43 \text{ persons} \right]$$

Next, the occupant load of the remainder of the floor must be calculated. The use is business, so a gross area factor of 100 ft<sup>2</sup> (9.3 m<sup>2</sup>) per person is chosen per Table 7.3.1.2. Because the net area usable as conference rooms has already been assigned an occupant load, that area can be subtracted from the gross floor area, and the remaining business use area is then assigned an occupant load as follows:

$$(4800 \text{ ft}^2 \text{ gross area}) - (640 \text{ ft}^2 \text{ net assembly use area}) = 4160 \text{ ft}^2$$

$$[(446 \text{ m}^2 \text{ gross area}) - (60 \text{ m}^2 \text{ net assembly use area}) = 386 \text{ m}^2]$$

$$\frac{4160 \text{ ft}^2 \text{ gross business use area}}{100 \text{ ft}^2 \text{ per person}} = 42 \text{ persons}$$

$$\left[ \frac{386 \text{ m}^2 \text{ gross business use area}}{9.3 \text{ m}^2 \text{ per person}} = 42 \text{ persons} \right]$$

Adding together the assembly use occupant load (43) and the business use occupant load (42) results in a minimum occupant load of 85 persons for the floor. See the paragraph that follows for an explanation of conditions under which the occupant load might be a number greater than that calculated using the floor area and occupant load factor calculation. However, the occupant load is not permitted to be a number smaller than that

calculated, even where the building operator plans to limit the number of occupants.

Egress capacity must be provided for at least the occupant load (expressed in number of persons) determined by dividing each area of the space by the appropriate occupant load factor. This calculated occupant load must serve as the minimum starting point for egress sizing, regardless of whether the building operator claims that the occupant load will never reach the occupant load determined by calculation. However, if the building operator plans to have more occupants present than the number determined by calculation using occupant load factors, the means of egress system must be sized to accommodate that larger number. In return for providing the larger egress system, the building operator is permitted to claim the larger number of persons as the occupant load. This concept is further explained in the commentary following 7.3.1.3.2.

Table 7.3.1.2 provides an occupant load factor for ambulatory health care use. The entry was changed for the 2015 edition of the Code from 100 ft<sup>2</sup> (9.3 m<sup>2</sup>) to 150 ft<sup>2</sup> (13.9 m<sup>2</sup>). The change reflects the technical committee’s judgment that ambulatory health care use spaces are not as densely populated as previously assumed. A calculation of occupant load using a factor of 150 ft<sup>2</sup> (13.9 m<sup>2</sup>) per person instead of the traditional 100 ft<sup>2</sup> (9.3 m<sup>2</sup>) per person results in an occupant load that is two-thirds as large.

Note that the occupant load for storage use classified as a storage occupancy (e.g., a warehouse) is determined not by calculation, but through negotiation between the designer or owner and the AHJ, based on actual use and population (see 42.1.7). There is no occupant load factor for storage use in a storage occupancy in Table 7.3.1.2. However, Table 7.3.1.2 provides occupant load factors for storage use in occupancies other than a storage occupancy (e.g., a central storage room in a hospital or a stock room in a department store) to allow occupant load to be aggregated via calculations for each use area on a building floor.

### 7.3.1.3 Occupant Load Increases.

**7.3.1.3.1** The occupant load in any building or portion thereof shall be permitted to be increased from the occupant load established for the given use in accordance with 7.3.1.2 where all other requirements of this Code are also met, based on such increased occupant load.

**7.3.1.3.2** The authority having jurisdiction shall be permitted to require an approved aisle, seating, or fixed equipment diagram to substantiate any increase in occupant load and shall be permitted to require that such a diagram be posted in an approved location.

The Code’s intent for other than assembly occupancies is not to restrict the occupant load of a building based on the floor area of the building. Nor is the Code specifying the minimum area needed by each occupant for efficient or sanitary use of the space. An occupant load is established for use in sizing the means of egress system and in determining thresholds at which

additional provisions, such as mandatory sprinklers, become applicable. If Code provisions can be met for a larger number of persons than the calculation determines, the larger number of occupants is permitted to be present and be considered as the occupant load, provided that the AHJ is satisfied that the egress system (including corridors, aisles, stairs, and other means of egress components) can accommodate the larger occupant load. For assembly occupancies, the increase in occupant load above the calculated number is restricted by 12.1.7 and 13.1.7, based on maximum density criteria. The subject is addressed two paragraphs below.

As an example of increasing the occupant load above the calculated number, a factory of 20,000 ft<sup>2</sup> (1860 m<sup>2</sup>) gross area would be assigned an occupant load of 200 persons if the typical 100 ft<sup>2</sup> (9.3 m<sup>2</sup>) per person occupant load factor were used. However, the occupant load would be permitted to be increased (e.g., to 300 persons to accommodate the occupant load of an electronic components manufacturing facility where personnel work side-by-side on assembly lines) if all Code provisions dependent on numbers of persons were met for the increased load.

Assembly occupancies have special but similar provisions for increasing occupant load. Densities greater than one person for each 5 ft<sup>2</sup> (0.46 m<sup>2</sup>) are prohibited, because movement speeds are reduced to a crawl where the density exceeds one person for each 3 ft<sup>2</sup> (0.28 m<sup>2</sup>) density. This density is approaching the jam point at which movement stops, as addressed in the commentary associated with 12.1.7.1.2 and 13.1.7.1.2.

**7.3.1.4 Exits Serving More than One Story.** Where an exit serves more than one story, only the occupant load of each story considered individually shall be used in computing the required capacity of the exit at that story, provided that the required egress capacity of the exit is not decreased in the direction of egress travel.

Paragraph 7.3.1.4 provides that, once a maximum required egress capacity is determined, such required capacity must be maintained — in the direction of egress travel — for the remainder of the egress system.

Required stair width is determined by the required egress capacity of each floor the stair serves, considered independently. It is not necessary to accumulate occupant loads from floor to floor to determine stair width. Each story or floor level is considered separately when calculating the occupant load to be served by the means of egress from that floor. The size or width of the stair need only accommodate the portion of the floor's occupant load assigned to that stair. However, in a multistory building, the floor requiring the greatest egress capacity dictates the minimum stair width from that floor to the level of exit discharge in the direction of egress travel. It is not permissible to reduce such stair width along the remainder of the stair runs encountered in traveling to the level of exit discharge, that is, stairs encountered in the direction of egress travel. Exits serving floors above the floor of greatest egress capacity are permitted to use egress

Exhibit 7.155

Capacity of exit stairs serving multiple floors.

components sized to handle the largest demand created by any floor served by that section of stair run.

Exhibit 7.155 illustrates the intent of 7.3.1.4. It is not necessary to accumulate required egress capacity from floor to floor; no decrease in egress capacity is permitted in the direction of egress travel.

**7.3.1.5 Capacity from a Point of Convergence.** Where means of egress from a story above and a story below converge at an intermediate story, the capacity of the means of egress from the point of convergence shall be not less than the sum of the required capacity of the two means of egress.

Exhibit 7.156 illustrates the intent of 7.3.1.5. Convergence from floors above and below requires the accumulation of required egress capacity. Paragraph 7.3.1.5 mandates that the required

Exhibit 7.156

Capacity of egress system from point on stairs where occupants from floors above and below converge.

capacity, not the actual or provided capacity, must be aggregated at point of convergence. Note that occupants of the second floor move down the stairs and converge with occupants of the basement, who are traveling up the stairs. From the merge point (i.e., the ground level stair landing) to the public way, the egress path must accommodate the 300-person combined occupant load represented as the sum of those persons moving downward and upward on the stair.

The occupants of the first floor (X) experience level travel through the stair enclosure; they are not considered to have merged from above or below, and egress capacity for the first floor occupants is not added to that of the second floor and basement.

**7.3.1.6 Egress Capacity from Balconies and Mezzanines.** Where any required egress capacity from a balcony or mezzanine passes through the room below, that required capacity shall be added to the required egress capacity of the room in which it is located.

Mezzanines and balconies are considered as part of the room in which they are located. Occupants of mezzanines and balconies experience the effects of a fire in the room to which such spaces are open as readily as do the occupants of those spaces. Thus, mezzanines and balconies must have their occupant load added to that of the room or space in which they are located if their egress passes through that room or space.

An example is depicted in [Exhibit 7.157](#). There is no direct access to the enclosed exit stair from the mezzanine; therefore, egress from the mezzanine is down the open stair and through the main floor. Thus, the street floor egress capacity must accommodate the occupant load of the street floor and that of the mezzanine. If the main floor has an occupant load of 200 persons

and the mezzanine has an occupant load of 50 persons, the egress capacity for the main floor must accommodate at least 250 persons.

## 7.3.2 Measurement of Means of Egress.

**7.3.2.1** The width of means of egress shall be measured in the clear at the narrowest point of the egress component under consideration, unless otherwise provided in [7.3.2.2](#) or [7.3.2.3](#).

**7.3.2.2** Projections within the means of egress of not more than 4½ in. (114 mm) on each side shall be permitted at a height of 38 in. (965 mm) and below. In the case of stair and landing handrails forming part of a guard, in accordance with [7.2.2.4.5.3](#), such projections shall be permitted at a height of 42 in. (1065 mm) and below.

**7.3.2.3** In health care and ambulatory health care occupancies, projections shall be permitted in corridors in accordance with [Chapters 18](#) through [21](#).

[Paragraph 7.3.2.2](#) permits maximum 4½ in. (114 mm) projections at each side of an egress component for purposes of determining width for use in egress capacity calculations, provided that such projections occur at a height of not more than 38 in. (965 mm), which is the maximum mounting height for handrails. Note that such encroachments are not limited to items such as handrails that are required by the *Code*. The encroachment might be the result of wainscoting applied to the lower portion of a wall, or it might be caused by the metal stringers to which metal pan stair treads and risers are welded.

A 4½ in. (114 mm) encroachment is permitted by [7.3.2.2](#) along stairs, corridors, passageways, and other components of the means of egress (other than door openings) for purposes of calculating egress capacity. The egress capacity of door openings is regulated by [7.2.1.2.2.1](#), which substitutes a maximum 3½ in. (90 mm) projection at each side of the door opening in place of the 4½ in. (114 mm) projection permitted by [7.3.2.2](#). [Figure A.7.2.1.2.2\(b\)](#) depicts the allowable encroachment at each side of a door opening.

[Exhibit 7.158](#) shows handrails along the right wall of the corridor in a medical office building. The handrails are permitted to encroach as much as 4½ in. (114 mm) into the corridor width in accordance with [7.3.2.2](#). Note that the cross-corridor door leaf (not the door opening) is provided with a handrail that serves as a corridor wall handrail when the door is held in its full open position.

For purposes of determining whether a door opening provides the minimum required width (such as that needed for a person in a wheelchair to pass through a door opening), see [7.2.1.2.1.1](#), [Figure A.7.2.1.2.1\(a\)](#), and [Figure A.7.2.1.2.1\(b\)](#). Similarly, the minimum 48 in. (1220 mm) clear width between handrails, as required by [7.2.12.2.3](#) for stairs serving areas of refuge, does not allow for encroachments, based on the need to provide sufficient clear width to carry a person in a wheelchair on the stair.

Required capacity of main floor with mezzanine egress through that floor.

Exhibit 7.158

Permitted handrail encroachment on required corridor width. (Photo courtesy of Jake Pauls)

Projections at or below 38 in. (965 mm) (i.e., handrail height), and not exceeding 4½ in. (114 mm), do not adversely restrict the effective egress width of stairs or corridors, because the human body is normally widest at shoulder level. Also, the body sway associated with walking, particularly on stairs, is greater at shoulder height than it is at waist height. Other projections, however, might constitute obstructions and cause impediments to the free flow of pedestrian travel. The *Code*, therefore, bases the measurements of widths of means of egress used for egress capacity calculation purposes on the clear, net, usable, unobstructed width. Only those projections specified are permitted to encroach on the required width without having to subtract the encroaching space from the overall width before performing the egress width calculation.

Paragraph 7.3.2.3 serves as a reminder that the provisions of 7.3.2 are modified to permit encroachments in health care and ambulatory health care occupancy corridors where the corridor width is at least 6 ft (1830 mm) — a width greater than the 36 in. (915 mm) minimum established for egress components by 7.3.4.1. See, for example, 19.2.3.4(2).

### 7.3.3\* Egress Capacity.

**A.7.3.3** In egress capacity calculations, standard rounding should be used.

**7.3.3.1** Egress capacity for approved components of means of egress shall be based on the capacity factors shown in Table 7.3.3.1, unless otherwise provided in 7.3.3.2.

Table 7.3.3.1 Capacity Factors

Area	Stairways (width/person)		Level Components and Ramps (width/person)	
	in.	mm	in.	mm
Board and care	0.4	10	0.2	5
Health care, sprinklered	0.3	7.6	0.2	5
Health care, nonsprinklered	0.6	15	0.5	13
High hazard contents	0.7	18	0.4	10
All others	0.3	7.6	0.2	5

A significant change in egress capacity calculations was introduced in the 1988 edition of the *Code*. The unit of exit width formerly used as a measure of egress capacity was replaced by a system of smaller increments of egress width and capacity. The newer method of using smaller increments (approximating a linear formula) provides increased egress capacity.

The differences between the *stairway* and *level components/ramps* capacity factors specified in Table 7.3.3.1 arise from the following:

1. Stairs entail a totally different type of movement, by both individuals and crowds, than do level and ramped components.
2. For stairs, there are differences in biomechanics, as well as a difficulty in the ability to see (or otherwise detect) the next stepping surface in order to avoid misstepping and suffering a fall and resulting injury. Exhibit 7.159 shows stair users looking for the next stepping surface.
3. The approximate ratio of 3 to 2, relating the required widths for vertical travel on stairs and level travel on floors, is based on previous ratios and on empirical observations.

The greater range of width requirements for different occupancies reflects the following two factors:

1. The need for a much more rapid egress time in the case of high hazard occupancies
2. The slower movement and greater need for assistance from others during evacuations in nonsprinklered health care and related institutional and semi-institutional occupancies

In summary, given the designer's knowledge of the occupancy, the occupant load of the floor level, and the type of egress component, the required minimum width for each component can be determined by simple multiplication (i.e., multiply the

occupant load by the appropriate width-per-person factor found in [Table 7.3.3.1](#) to obtain the minimum width of the component under consideration). If the width of the component under consideration is known, divide that width by the appropriate width-per-person factor to obtain the number of persons the component can accommodate over the entire evacuation. These calculated minimum widths are then considered along with other *Code* requirements, including minimum widths based on other factors, to design a system in which performance will be closely matched from one part of the system to another.

**7.3.3.2\*** For stairways wider than 44 in. (1120 mm) and subject to the 0.3 in. (7.6 mm) width per person capacity factor, the capacity shall be permitted to be increased using the following equation:

$$C = 146.7 + \left( \frac{W_n - 44}{0.218} \right) \quad [7.3.3.2]$$

where:

$C$  = capacity, in persons, rounded to the nearest integer

$W_n$  = nominal width of the stair as permitted by [7.3.2.2](#) (in.)

**A.7.3.3.2** The effective capacity of stairways has been shown by research to be proportional to the effective width of the

**Exhibit 7.159**

Stair users looking for next stepping surface. (Photo courtesy of Jake Pauls)

stairway, which is the nominal width minus 12 in. (305 mm). This phenomenon, and the supporting research, were described in the chapter, “Movement of People,” in the first, second, and third editions of the *SFPE Handbook of Fire Protection Engineering* and was also addressed in Appendix D of the 1985 edition of NFPA 101, among several other publications. In 1988, this appendix was moved to form Chapter 2 of the 1988 edition of NFPA 101M, *Alternative Approaches to Life Safety*. (This document was later designated as NFPA 101A, *Guide on Alternative Approaches to Life Safety*, and this chapter remained in the document through the 1998 edition.) In essence, the effective width phenomenon recognizes that there is an edge or boundary effect at the sides of a circulation path. It has been best examined in relation to stairway width, where the edge effect was estimated to be 6 in. (150 mm) on each side, but a similar phenomenon occurs with other paths, such as corridors and doors, although quantitative estimates of their edge effect are not as well established as they have been for stairways, at least those stairways studied in Canada during the late 1960s through the 1970s in office building evacuation drills and in crowd movement in a variety of buildings with assembly occupancy.

More recent studies have not been performed to determine how the edge effect might be changing (or has changed) with demographic changes to larger, heavier occupants moving more slowly, and thus swaying laterally, to maintain balance when walking. The impact of such demographic changes, which are significant and influential for evacuation flow and speed of movement on stairs, for example, has the effect of increasing the time of evacuation in a way that affects all stair widths, but will be most pronounced for nominal widths less than 56 in. (1422 mm).

Without taking into account occupant demographic changes in the last few decades that affect evacuation performance, especially on stairs, the formula for enhanced capacity of stairways wider than 44 in. (1120 mm) assumes that any portion of the nominal width greater than 44 in. (1120 mm) is as effective proportionally as the effective width of a nominal 44 in. (1120 mm) stair, that is, 32 in. (810 mm). Thus, the denominator (0.218) in the equation is simply the effective width of 32 in. (810 mm) divided by the capacity of 147 persons that is credited, by the 0.3 in. (7.6 mm) capacity factor in [Table 7.3.3.1](#), to the corresponding nominal width, 44 in. (1120 mm).

The resulting permitted stairway capacities, based on occupant load of single stories (in accordance with [7.3.1.4](#)), for several stairway widths are shown in [Table A.7.3.3.2](#).

The enhanced capacity provision of [7.3.3.2](#) permits stairs that are wider than 44 in. (1120 mm), for which the 0.3 in. (7.6 mm) per person capacity factor from the last row (i.e., the entry for “all others”) of [Table 7.3.3.1](#) is applied, to be credited with more capacity than results from the standard calculation performed by dividing the clear width of the stair by the 0.3 in. (7.6 mm) per person capacity factor. The rationale for the enhanced capacity allowance is detailed in the extensive commentary on [A.7.3.3.2](#).

Table A.7.3.3.2 Stairway Capacities

Permitted Capacity (no. of persons)	Nominal Width		Clear Width Between Handrails <sup>a</sup>		Effective Width	
	in.	mm	in.	mm	in.	mm
120 <sup>b</sup>	36	915	28	710	24	610
147	44	1120	36	915	32	810
202	56	1420	48	1220	44	1120
257	68	1725	60	1525 <sup>c</sup>	56	1420

<sup>a</sup>A reasonable handrail incursion of only 4 in. (100 mm), into the nominal width, is assumed on each side of the stair, although 7.3.3.2 permits a maximum incursion of 4½ in. (114 mm) on each side.

<sup>b</sup>Other Code sections limit the occupant load for such stairs more severely, (e.g., 50 persons in 7.2.2.2.1.2). Such lower limits are partly justified by the relatively small effective width of such stairs, which, if taken into account by Table 7.3.3.1, would result in a correspondingly low effective capacity of only 110 persons (24 divided by 0.218), or a more realistic capacity factor of 0.327, applicable to nominal width.

<sup>c</sup>A clear width of 60 in. (1525 mm) is the maximum permitted by the handrail reachability criteria of 7.2.2.4.1.2. Although some prior editions of the Code permitted wider portions of stairs [up to 88 in. (2240 mm), between handrails], such wider portions are less effective for reasonably safe crowd flow and generally should not be used for major crowd movement. To achieve the maximum possible, reasonably safe egress capacity for such stairs, retrofit of an intermediate — not necessarily central — handrail is recommended; for example, with an intermediate handrail located 36 in. (915 mm) from the closest side handrail. In this case, the effective capacity would be 358 persons for the formerly permitted, now retrofitted, stair. This is based on a retrofitted, effective width of about 78 in. (1980 mm) [subtracting 2 in. (51 mm) from each usable side of a handrail and assuming a 2 in. (51 mm) wide, retrofitted intermediate handrail].

Equation 7.3.3.2 is presented only in inch-pound units. Where SI units are used, the equation for calculating capacity,  $C$ , is as follows:

$$C = 146.7 + \left[ \frac{(Wn - 1120)}{5.45} \right]$$

where the nominal stair width,  $Wn$ , is expressed in mm.

An example of use of the enhanced capacity permitted by 7.3.3.2 follows. A 56 in. (1420 mm) stair has encroachments at handrail height and below that do not exceed the 4½ in. (114 mm) permitted at each side by 7.3.2.2. The stair exceeds the 44 in. (1120 mm) width specified in 7.3.3.2 and is in a business occupancy, so as to be subject to the 0.3 in. (7.6 mm) per person capacity factor from the last row of Table 7.3.3.1. The traditional capacity calculation involves taking the 56 in. (1420 mm) clear width and dividing it by 0.3 in. (7.6 mm) per person, which results in a traditional capacity of 187 persons. The nominal width of the stair, for purposes of performing the enhanced capacity

calculation permitted by 7.3.3.2, is the full 56 in. (1420 mm) clear width, and the calculation is performed as follows:

$$\text{Enhanced capacity, } C = 146.7 + \left[ \frac{(56 \text{ in.} - 44 \text{ in.})}{0.218} \right]$$

$$C = 146.7 + \left[ \frac{12}{0.218} \right]$$

$$C = 146.7 + 55$$

$$C = 202 \quad [7.3.3.2]$$

In SI units:

$$\text{Enhanced capacity, } C = 146.7 + \left[ \frac{(1420 \text{ mm} - 1120 \text{ mm})}{5.45} \right]$$

$$C = 146.7 + \left[ \frac{300}{5.45} \right]$$

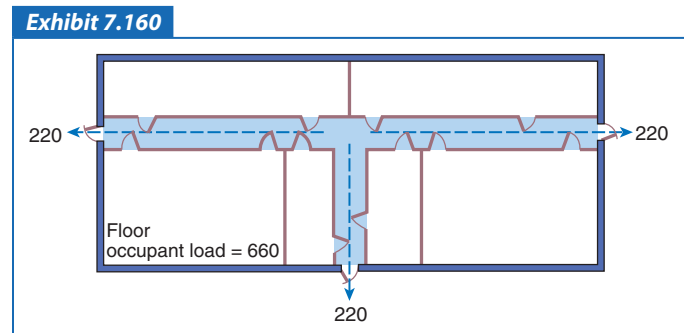

$$C = 146.7 + 55$$

$$C = 202$$

Note that 7.2.2.4.1.2(2)(b) prohibits the enhanced capacity option of 7.3.3.2 from being applied to existing stairs where portions of the stair are more than 30 in. (760 mm) from a handrail, even though the provision of 7.2.2.4.1.2(2)(a) would otherwise permit 44 in. (1120 mm). In other words, an existing stair is held to the same intermediate handrail criterion as new stairs, as found in 7.2.2.4.1.2(1), if the existing stair is to make use of the increased capacity offered by Equation 7.3.3.2.

**7.3.3.3** The required capacity of a corridor shall be the occupant load that utilizes the corridor for exit access divided by the required number of exits to which the corridor connects, but the corridor capacity shall be not less than the required capacity of the exit to which the corridor leads.

An example of the provisions of 7.3.3.2 is shown in Exhibit 7.160. A corridor system serves a floor with a 660-person occupant load and three means of egress. The corridor must be wide enough to accommodate the portion of the floor's occupant load that it serves. Typical design practice is to divide the floor occupant load by the number of means of egress provided (see 7.3.1.1.2 for provisions that lead to balanced use where two exits are

Corridor capacity.

required in new construction). In this three-exit example, no portion of the corridor needs capacity for more than one-third of the floor's occupant load, which by calculation ( $660 \div 3$ ) is 220 persons. The required corridor width is determined to be 44 in. (1120 mm) wide [ $220 \text{ persons} \div 0.2 \text{ in. (5 mm) per person}$ ]. Some occupancies, such as health care occupancies, require wider minimum corridor widths than the 44 in. (1120 mm) width calculated.

The *Code* states that the required corridor capacity cannot be less than the required capacity of the exit to which it leads. In other words, the corridor is not permitted to create a bottleneck that is too narrow and impedes the flow of occupants to the exit door opening.

### 7.3.4 Minimum Width.

**7.3.4.1** The width of any means of egress, unless otherwise provided in 7.3.4.1.1 through 7.3.4.1.3, shall be as follows:

- (1) Not less than that required for a given egress component in this chapter or Chapters 11 through 43
- (2) Not less than 36 in. (915 mm) where another part of this chapter and Chapters 11 through 43 do not specify a minimum width

**7.3.4.1.1\*** The width of exit access serving not more than six people and having a length not exceeding 50 ft (15 m) shall meet both of the following criteria:

- (1) The width shall be not less than 18 in. (455 mm), at and below a height of 38 in. (965 mm), and not less than 28 in. (710 mm) above a height of 38 in. (965 mm).
- (2) A width of not less than 36 in. (915 mm) for new exit access, and not less than 28 in. (710 mm) for existing exit access, shall be capable of being provided without moving permanent walls.

**A.7.3.4.1.1** The criteria of 7.3.4.1.1, as initially written, were intended to provide for minimum widths for small spaces such as individual offices. The intent is that these reductions in required width apply to spaces formed by furniture and movable walls, so that accommodations can easily be made for mobility-impaired individuals. One side of a path could be a fixed wall, provided that the other side is movable. This does not exempt the door widths or widths of fixed-wall corridors, regardless of the number of people or length. The allowance for reduction in width has been expanded to include all exit accesses serving not more than six people where the travel length along the reduced-width path does not exceed 50 ft (15 m), regardless of occupancy or use of the space.

Figure A.7.3.4.1.1(a) and Figure A.7.3.4.1.1(b) present selected anthropometric data for adults. The male and female figures depicted in the figures are average, 50th percentile, in size. Some dimensions apply to very large, 97.5 percentile, adults (noted as 97.5 P).

The provision of 7.3.4.1(2) was revised for the 2012 edition of the *Code*. It previously required a minimum 36 in. (915 mm) width and did not have the additional text permitting another provision of the *Code* to allow a lesser width.

Paragraph 7.3.4.1.1 and the associated annex material explain the intent behind permitting spaces, such as individual offices or workstations, an exemption from the 36 in. (915 mm) minimum width requirement of 7.3.4.1(2) for new construction. If any one path (e.g., a "mini-aisle") requires a maximum of six people to travel not more than 50 ft (15 m) to reach a minimum 36 in. (915 mm) wide egress path (e.g., a major aisle), the path is permitted to be as narrow as 28 in. (710 mm). The width of the path is permitted to be reduced further to 18 in. (455 mm) near the floor, but not at points more than 38 in. (965 mm) above the floor, as might be characteristic of a small floor-mounted bookcase.

Other paths within the same room are permitted the same reduction in required width, provided that each individually meets the six-person and 50 ft (15 m) criteria for travel to a minimum 36 in. (915 mm) wide egress path. This is illustrated in Exhibit 7.161. The minimum 28 in. (710 mm) width (shown as

Minimum exit access width created by movable furniture and partitions.

**Figure A.7.3.4.1.1(a)** Anthropometric Data (in in.) for Adults; Males and Females of Average, 50th Percentile, Size; Some Dimensions Apply to Very Large, 97.5 Percentile (97.5 P), Adults.

dimension  $x$ ) permitted by 7.3.4.1.1(1) is a relaxation of the 36 in. (915 mm) minimum required by 7.3.4.1(2). This width can be further reduced to 18 in. (455 mm) (shown as dimension  $y$ ) at floor level up to a height of 38 in. (965 mm) above the floor. Both width reduction options are conditional on a maximum of six people traveling not more than 50 ft (15 m) along a resultant miniaisle to reach a minimum 36 in. (915 mm) wide exit access component, such as an aisle.

Use of 7.3.4.1.1 is not limited to business occupancies. The same provisions could be applied to factory workstations in an

industrial occupancy or to library study carrels in an assembly occupancy.

The provision of 7.3.4.1.1(2), related to the ability to increase the available width to 36 in. (915 mm) without moving permanent walls, is intended to keep the overall width exemption from denying accessibility to persons with severe mobility impairment. For example, if a person who uses a wheelchair has seniority to claim the prime workstation with a window to the outside, but such workstation is currently arranged so that it is accessed by a miniaisle only 28 in. (710 mm) wide, the building

**Figure A.7.3.4.1.1(b)** Anthropometric Data (in mm) for Adults; Males and Females of Average, 50th Percentile, Size; Some Dimensions Apply to Very Large, 97.5 Percentile (97.5 P), Adults.

maintenance engineer must be able to detach from the floor, reposition, and reattach cubicle partitions to increase the min-aisle to a 36 in. (915 mm) width.

**7.3.4.1.2** In existing buildings, the width of exit access shall be permitted to be not less than 28 in. (710 mm).

**7.3.4.1.3** The requirement of 7.3.4.1 shall not apply to the following:

(1) Doors as otherwise provided for in 7.2.1.2

(2) Aisles and aisle accessways in assembly occupancies as otherwise provided in Chapters 12 and 13

(3) Industrial equipment access as otherwise provided in 40.2.5.3

The minimum width required in any egress path is dependent on the occupancy and is thus specified in Chapters 12 through 42 for individual occupancies. The widths are based on experience and on observations of the manner in which people move along paths used for egress purposes. The minimum width

permitted for any new egress component, other than a door opening, is 36 in. (915 mm), but most occupancies require additional width for specific components. Educational occupancies require a corridor width of not less than 6 ft (1830 mm). New health care occupancies require a corridor width of not less than 8 ft (2440 mm), which reflects the need to move bedridden patients and multiple lines of people along the path to an exit. Hotels, apartment buildings, and business occupancies generally require 44 in. (1120 mm) minimum width corridors. Some occupancies rely wholly on the provisions of 7.3.4.1, so as not to specify their own minimum widths.

**7.3.4.2** Where a single exit access leads to an exit, its capacity in terms of width shall be not less than the required capacity of the exit to which it leads.

**7.3.4.3** Where more than one exit access leads to an exit, each shall have a width adequate for the number of persons it accommodates.

The intent of 7.3.4.2 and 7.3.4.3 is to balance the flow of persons from the exit access to the exit to avoid a bottleneck and to ensure that the occupants being served by the exit can, in fact, reach it. The design and sizing of egress paths involve apportioning part of the overall occupant load to the various available paths. Where there are multiple paths, no one path needs to accommodate all of the occupants by itself.

## 7.4\* Number of Means of Egress

**A.7.4** Section 7.4 requires a minimum number of means of egress, unless otherwise specified by an occupancy chapter in subsection \_\_\_\_\_.2.4, which addresses number of means of egress. Several occupancy chapters establish not only the minimum number of means of egress but also the minimum number of actual exits that must be provided on each floor. For example, for new educational occupancies, 14.2.4 requires access to two exits and further requires that both of the exits be provided on the floor. In contrast, for industrial occupancies, 40.2.4.1.1 requires access to two exits and further requires that at least one of the exits be located on the floor. Access to the other exit can involve traveling to another floor via an egress component such as an open stair, provided that such open stair is permitted by the occupancy chapter's provisions for the protection of vertical openings.

In most occupancy chapters, meeting the requirements for egress capacities and travel distances means the required minimum number of means of egress will automatically be met. However, in occupancies characterized by high occupant loads, such as assembly and mercantile occupancies, compliance with requirements for more than two exits per floor might require specific attention.

### 7.4.1 General.

**7.4.1.1** The number of means of egress from any balcony, mezzanine, story, or portion thereof shall be not less than two, except under one of the following conditions:

- (1) A single means of egress shall be permitted where permitted in Chapters 11 through 43.
- (2) A single means of egress shall be permitted for a mezzanine or balcony where the common path of travel limitations of Chapters 11 through 43 are met.

Most of the occupancy chapters provide redundancy with respect to the number of means of egress by requiring at least two means of egress. Some occupancies identify specific arrangements under which only a single means of egress is required. Where large numbers of occupants are to be present on any floor or portion of a floor in new construction, more than two means of egress must be provided as required by 7.4.1.2.

Mezzanines are required to have the same number of means of egress as any story of the building, unless an occupant can reach either the single exit or a point (at or past the bottom of a single open stair) where access to two exits becomes available within the allowable common path of travel permitted for the applicable occupancy.

Exhibit 7.162 illustrates the mezzanine provisions of 7.4.1.1 and 7.4.1.1(2), which are not intended to override the provisions for openness of mezzanines imposed by 8.6.10.3. In Exhibit 7.162, Part (a) illustrates the requirement for a minimum of two means of egress per 7.4.1.1. One means of egress is an open stair to the floor below, and the other is an enclosed exit stair. Both could be open stairs to the floor below, unless the openness requirements of 8.6.10.3 are not met. If the mezzanine were enclosed, such that the enclosed area had an occupant load of more than 10 persons, 8.6.10.3 would require a second means of egress [similar to the enclosed exit stair in Part (a)] that provides direct access from the enclosed area to an exit at the mezzanine level. In Part (b) of Exhibit 7.162, a single means of egress is permitted in accordance with 7.4.1.1(2), because the common path of travel is within the limits specified for the occupancy involved and the 10-person enclosed area criterion of 8.6.10.3 is not exceeded.

See also Section 7.5 with respect to remoteness of exits and common paths of travel, 7.6.5 with respect to measuring travel distance in the plane of the tread nosings on open exit access stairs, and 8.6.10 on mezzanines.

**7.4.1.2** The number of means of egress from any story or portion thereof, other than for existing buildings as permitted in Chapters 11 through 43, shall be as follows:

- (1) Occupant load more than 500 but not more than 1000 — not less than 3
- (2) Occupant load more than 1000 — not less than 4

Exhibit 7.162

Number of means of egress from mezzanines.

Chapter 7 requires a minimum number of means of egress, unless otherwise specified by the occupancy chapters. Several occupancies establish not only the minimum number of means of egress but also the minimum number of actual exits that must be provided on each floor. For example, for new educational occupancies, 14.2.4.2 requires access to two exits and further requires that both of the exits be provided on the floor. In contrast, for industrial occupancies, 40.2.4.1.1 requires access to two exits and further requires that at least one of the exits is to be located on the floor. Access to the other exit can involve traveling to another floor via an egress component such as an open stair, provided that such open stair is permitted by the provisions for protection of vertical openings.

In most occupancies, meeting the requirements for egress capacities and travel distances means the required minimum number of means of egress will automatically be met. However, in occupancies characterized by high occupant loads, such as assembly and mercantile occupancies, compliance with requirements for more than two exits per floor might require specific attention.

**7.4.1.3** Accessible means of egress in accordance with 7.5.4 that do not utilize elevators shall be permitted to serve as any or all of the required minimum number of means of egress.

Because an accessible means of egress can effectively serve the needs of persons with mobility impairments, the same accessible means of egress should effectively serve the needs of persons without disabilities. Therefore, the Code permits accessible means of egress to fulfill any requirements for means of egress. However, this permission does not apply to elevators because of the small number of occupants accommodated during each run of the elevator and concerns that the elevator might be automatically called out of service upon the detection of smoke in the elevator machine room or an elevator lobby or landing on any floor served by the elevator. See Section 7.14 for provisions for occupant-controlled evacuation elevators, which receive no credit as satisfying any means of egress requirements.

**7.4.1.4** The occupant load of each story considered individually shall be required to be used in computing the number of means of egress at each story, provided that the required number of means of egress is not decreased in the direction of egress travel.

Similar to the procedures for determining required egress capacity (see 7.3.1.4), the number of required means of egress is based on a floor-by-floor consideration, rather than the accumulation of the occupant loads of all floors. For example, see Exhibit 7.163, where the fourth floor of the building has an occupant load of 700 persons and would require three means of egress. The third floor of the same building has an occupant load of 400 persons and would require two means of egress; regardless of the fact that the two floors together have an occupant load in excess of 1000 persons, four means of egress are not required. However, the number of means of egress cannot decrease as an occupant proceeds along the egress path. The three exits required from the fourth floor in this example cannot be merged into two exits on the third floor, even though the third floor requires only two exits. On any floor requiring only two exits, one of the three exits could be left inaccessible (blind) on that floor, as shown at Exit 3 in Exhibit 7.163 on the third and fifth floors. The second floor, with an occupant load of 1500 persons, requires a fourth means of egress.

**7.4.1.5** Doors other than the hoistway door; the elevator car door; and doors that are readily openable from the car side without a key, a tool, special knowledge, or special effort shall be prohibited at the point of access to an elevator car.

Paragraph 7.4.1.5 prohibits the installation of a door assembly at the entrance to an elevator, unless that door leaf is readily operable by those in the elevator. This prohibition prevents entrapment between the elevator and the door assembly. The primary concern is the potential for an occupant to enter this small space and become trapped during a fire. Exhibit 7.164 shows doors at the entrance to an elevator. Note the door lever on the door leaf

**Exhibit 7.163**

Minimum number of required means of egress for new construction.

**Exhibit 7.164**

Permitted doors at entrance to elevator.

at the right side. The door lever provides occupants of the elevator with the required latch release to open the door.

#### 7.4.1.6 Elevator Landing and Lobby Exit Access.

**7.4.1.6.1** Each elevator landing and lobby shall have access to at least one exit.

**7.4.1.6.2** The elevator landing and lobby exit access required by 7.4.1.6.1 shall not require the use of a key, a tool, special knowledge, or special effort, unless permitted by 7.4.1.6.3.

**7.4.1.6.3** Doors separating the elevator lobby from the exit access required by 7.4.1.6.1 shall be permitted to be electronically locked in accordance with 7.2.1.6.3.

The purpose of 7.4.1.6.1 and 7.4.1.6.2 is to ensure that an occupant who has gained access to an elevator lobby can get out of the lobby without the use of a tool or key. It is not uncommon, especially in office buildings where a tenant occupies an entire floor, for the elevator lobby door assemblies to the tenant space to be locked after normal business hours to prevent entry into the tenant space. This problem is illustrated in Exhibit 7.165. Because the door assemblies between the elevator lobby and the tenant spaces can be locked, access to an exit is not assured to a person who arrives at the floor via elevator. At least one exit must be accessible from the elevator lobby. The situation can be corrected by repositioning one of the exit stair enclosures depicted at the top of the exhibit so that it is accessed directly from within the elevator lobby.

The provision of 7.4.1.6.3, rather than providing the detailed criteria required of locked elevator lobby exit access door assemblies, references the criteria of 7.2.1.6.3 as an exemption to the requirements of 7.4.1.6.1 and 7.4.1.6.2. The provisions of 7.2.1.6.3 for elevator lobby exit access door assemblies locking are correctly positioned within the 7.2.1 subsection on door openings and, more importantly, within 7.2.1.6, special locking arrangements provisions, as locked elevator lobby exit access doors are a special form of permitted door assembly locking. See the commentary following A.7.2.1.6.3(14).

**Exhibit 7.165**

Exit access from an elevator lobby.

## 7.4.2 Spaces About Electrical Equipment.

**7.4.2.1 600 Volts, Nominal, or Less.** The minimum number of means of egress for working space about electrical equipment, other than existing electrical equipment, shall be in accordance with *NFPA 70, National Electrical Code*, Section 110.26(C).

**7.4.2.2 Over 600 Volts, Nominal.** The minimum number of means of egress for working space about electrical equipment, other than existing electrical equipment, shall be in accordance with *NFPA 70, National Electrical Code*, Section 110.33(A).

The provisions of 7.4.2 serve as a reminder that *NFPA 70®, National Electrical Code®*,<sup>20</sup> has criteria for ingress and egress for working space around electrical equipment that are more specific, and potentially more stringent, than those of this Code. Users had complained that, after designing an egress system in accordance with this Code, they were cited for not complying with *NFPA 70*.

## 7.5 Arrangement of Means of Egress

### 7.5.1 General.

**7.5.1.1** Exits shall be located, and exit access shall be arranged, so that exits are readily accessible at all times.

**7.5.1.1.1\*** Where exits are not immediately accessible from an open floor area, continuous passageways, aisles, or corridors leading directly to every exit shall be maintained and shall be arranged to provide access for each occupant to not less than two exits by separate ways of travel, unless otherwise provided in 7.5.1.1.3 and 7.5.1.1.4.

**A.7.5.1.1.1** See A.7.5.1.5.

**7.5.1.1.2** Exit access corridors shall provide access to not less than two approved exits, unless otherwise provided in 7.5.1.1.3 and 7.5.1.1.4.

**7.5.1.1.3** The requirements of 7.5.1.1.1 and 7.5.1.1.2 shall not apply where a single exit is permitted in Chapters 11 through 43.

**7.5.1.1.4** Where common paths of travel are permitted for an occupancy in Chapters 11 through 43, such common paths of travel shall be permitted but shall not exceed the limit specified.

Paragraphs 7.5.1.1.1 and 7.5.1.1.2 reinforce the desirability of always being able to move in different directions from any location, so as to allow different paths of travel to different exits. However, typical floor layouts and furnishing arrangements often create spaces where travel in a single direction is necessary for a limited distance before it becomes possible to travel in different directions.

Paragraph 7.5.1.1.3 recognizes that a single exit creates a condition under which travel is possible in only one direction.

The conditions under which an occupancy chapter permits a single exit usually produce a situation that is as safe as, or safer than, a building that is provided with two exits but that includes substantial common path of travel before access to both exits is possible.

Paragraph 7.5.1.1.4 recognizes common paths of travel within the limits set by the individual occupancy chapters. For additional information on common paths of travel, see A.7.5.1.5.

**7.5.1.2** Corridors shall provide exit access without passing through any intervening rooms other than corridors, lobbies, and other spaces permitted to be open to the corridor, unless otherwise provided in 7.5.1.2.1 and 7.5.1.2.2.

**7.5.1.2.1** Approved existing corridors that require passage through a room to access an exit shall be permitted to continue to be used, provided that all of the following criteria are met:

- (1) The path of travel is marked in accordance with Section 7.10.
- (2) Doors to such rooms comply with 7.2.1.
- (3) Such arrangement is not prohibited by the applicable occupancy chapter.

The exit access arrangement illustrated in Exhibit 7.166 is deficient with respect to the requirement of 7.5.1.2 mandating that corridors provide access to at least two exits without passing through intervening rooms (other than corridors and lobbies). Occupants reaching the corridor have access only to Exit B without leaving the protection afforded by the corridor. Paragraph 7.5.1.2 requires access to both Exit A and Exit B without leaving the corridor and traveling within another use area. One possible solution to this problem would be to extend the corridor walls to the far left of the floor to connect directly with exit stair enclosure A.

Paragraph 7.5.1.2.1 recognizes the continued use of existing corridors that force occupants to travel through a room to access

Exhibit 7.166

Deficient corridor exit access.

an exit where such existing corridors are approved. Per the definition of 3.2.1, the term *approved* means acceptable to the authority having jurisdiction, so it is the current AHJ who must approve the existing corridor arrangement in order for it to be continued in use. If the exemption were not permitted, existing arrangements that were in compliance with earlier editions of the Code might suddenly be considered noncompliant.

**7.5.1.2.2** Corridors that are not required to be fire resistance rated shall be permitted to discharge into open floor plan areas.

**7.5.1.3** Remoteness shall be provided in accordance with 7.5.1.3.1 through 7.5.1.3.7.

The provisions of 7.5.1.3.1 through 7.5.1.3.7 address the remoteness of exit accesses, the remoteness of exits, and the remoteness of exit discharges.

The concept of remoteness of exit accesses is illustrated in Exhibit 7.167 [which is an adaptation of Figure A.7.5.1.3.2(c)]. For purposes of this illustration, the building is new construction and is not sprinklered, so as to be subject to both the qualitative remoteness criterion of 7.5.1.3.1 and the quantitative, one-half diagonal measurement remoteness criterion of 7.5.1.3.2. Exit 1 and Exit 2, which are about as remotely located from each other as physically possible, easily comply with the one-half diagonal separation distance criterion of 7.5.1.3.2 for exits. Yet, the L-shaped partition around which occupants must travel to reach Exit 1 has the effect of making the exit accesses less remotely located from each other than the exits, as all occupants are drawn toward Exit 2 before reaching point A, where access to Exit 1 becomes possible. The distance from point A to point B designates the separation distance between exit accesses that the requirements of 7.5.1.3.1 and 7.5.1.3.2 are intended to regulate. Without having to resort to measuring with a scale, it is

apparent that the exit accesses do not meet the minimum one-half diagonal ( $\frac{1}{2} D$ ) requirement of 7.5.1.3.2. It is not obvious whether the distance from point A to point B provides sufficient separation between exit accesses to meet the qualitative provision of 7.5.1.3.1, which requires that the exit accesses be remotely located from each other to minimize the possibility that more than one of the exit accesses has the potential to be blocked by any one fire or other emergency condition. Such judgment is left to the authority having jurisdiction, which might be influenced by the fact that the diagonal measurement criterion of 7.5.1.3.2 was not met. If the building were sprinklered, the provision of 7.5.1.3.3 would be applied in lieu of that of 7.5.1.3.2, so as to decrease the required separation distance from one-half the diagonal to one-third the diagonal. Again, although less obvious than before, the remoteness test for the exit accesses would fail, as the distance from point A to point B is less than one-third the diagonal ( $\frac{1}{3} D$ ).

The provisions of 7.5.1.3.1 through 7.5.1.3.3, in addition to regulating the remoteness of exit accesses and the remoteness of exits, require that exit discharges be remotely located from each other. The concept of remoteness of exit discharges is illustrated in Exhibit 7.168. The shaded paths outside the nonsprinklered building are exit discharges. One provides the exit discharge path from Exit 1 to the public way, and the other provides the exit discharge path from Exit 2 to the public way. The proximity of the two exit discharge paths, measured as the distance between point A and point B, is insufficient to meet the

Testing the remoteness of exit accesses.

Testing the remoteness of exit discharges.

one-half diagonal ( $\frac{1}{2} D$ ) requirement of 7.5.1.3.2. Although Exit 1 is sufficiently remote from Exit 2 to comply with 7.5.1.3.2, the exit discharges are not, and the situation must be remedied. One possible solution might be to move Exit 1 to the far right end of the building exterior wall in which it is currently positioned.

Exhibit 7.169 addresses the case of testing the remoteness of exit discharges where three exits are provided. The provision of 7.5.1.3.6 requires that at least two of the required exit discharges be remote from each other. The provision of 7.5.1.3.7 requires that any additional required exit discharges be located so that, if one of the required exit discharges becomes blocked, the others are available. Assume that the single-story, nonsprinklered building depicted has an occupant load of more than 500 persons, so as to require three means of egress in accordance with 7.4.1.2. The separation distance between the exit discharges from Exit 1 and Exit 3, measured as the distance from point C to point E, is sufficient to meet the one-half diagonal ( $\frac{1}{2} D$ ) requirement of 7.5.1.3.2. Thus, two of the three required exit discharges are remote from each other as required by 7.5.1.3.6. It is left to the authority having jurisdiction to decide whether the loss of the exit discharge serving Exit 1 leaves the exit discharge serving Exit 2 available as required by 7.5.1.3.7.

Testing the remoteness of exit discharges where three exits are provided.

The Code provides no further guidance on what the term *available* means, other than to connote that an exit discharge can be judged as being available without being remote from its nearest neighbor, as defined by the criteria of 7.5.1.3.1, 7.5.1.3.2, or 7.5.1.3.3.

**7.5.1.3.1** Where more than one exit, exit access, or exit discharge is required from a building or portion thereof, such exits, exit accesses, or exit discharges shall be remotely located from each other and be arranged to minimize the possibility that more than one has the potential to be blocked by any one fire or other emergency condition.

It is a precept of life safety in buildings, repeated many times in the Code, that if multiple exits are required, they need to be not only separate, but also remote, from one another. Although the objective of this requirement is clear (if one exit is blocked by smoke or fire, the other needs to be maintained available), the term *remote* cannot always be clearly defined.

Where exits are located at each end of a long corridor or at each end or side of a building, they qualify as remotely located exits. However, core-type buildings with elevators, service shafts, and stairs in one central or side core introduce some challenging problems with respect to exit remoteness.

**7.5.1.3.2\*** Where two exits, exit accesses, or exit discharges are required, they shall be located at a distance from one another not less than one-half the length of the maximum overall diagonal dimension of the building or area to be served, measured in a straight line between the nearest edge of the exits, exit accesses, or exit discharges, unless otherwise provided in 7.5.1.3.3 through 7.5.1.3.5.

**A.7.5.1.3.2** Figure A.7.5.1.3.2(a) through Figure A.7.5.1.3.2(e) illustrate the method of measurement intended by 7.5.1.3.2.

Figure A.7.5.1.3.2(a) Diagonal Rule for Exit Remoteness.

**Figure A.7.5.1.3.2(b)** Diagonal Rule for Exit and Exit Access Door Remoteness.

**Figure A.7.5.1.3.2(c)** Diagonal Rule for Exit and Access Remoteness.

**7.5.1.3.3** In buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with **Section 9.7**, the minimum separation distance between two exits, exit accesses, or exit discharges, measured in accordance with **7.5.1.3.2**, shall be not less than one-third the length of the maximum overall diagonal dimension of the building or area to be served.

**7.5.1.3.4\*** In other than high-rise buildings, where exit enclosures are provided as the required exits specified in **7.5.1.3.2** or

**Figure A.7.5.1.3.2(d)** Exit Separation and Diagonal Measurement of Area Served.

**7.5.1.3.3** and are interconnected by not less than a 1-hour fire resistance-rated corridor, exit separation shall be measured along the shortest line of travel within the corridor.

**A.7.5.1.3.4** **Figure A.7.5.1.3.4** illustrates the method of measuring exit separation distance along the line of travel within a minimum 1-hour fire resistance-rated corridor.

**7.5.1.3.5** In existing buildings, where more than one exit, exit access, or exit discharge is required, such exits, exit accesses, or exit discharges shall be exempt from the diagonal measurement separation distance criteria of **7.5.1.3.2** and **7.5.1.3.3**, provided that such exits, exit accesses, or exit discharges are remotely located in accordance with **7.5.1.3.1**.

**7.5.1.3.6** In other than existing buildings, where more than two exits, exit accesses, or exit discharges are required, at least two of the required exits, exit accesses, or exit discharges shall be arranged to comply with the minimum separation distance requirement.

**7.5.1.3.7** The balance of the exits, exit accesses, or exit discharges specified in **7.5.1.3.6** shall be located so that, if one becomes blocked, the others are available.

Since 1988, the *Code* has contained a remoteness formula referred to as the “one-half diagonal rule.” This basic rule is stated in **7.5.1.3.2**. **Figure A.7.5.1.3.2(a)** through **Figure A.7.5.1.3.2(e)** detail the application of the rule. The *Code* uses the one-half diagonal rule to quantify remoteness and to make certain that

**Figure A.7.5.1.3.2(e)** Diagonal Measurement for Unusually Shaped Areas.

**Figure A.7.5.1.3.4** Exit Separation Measured Along Corridor Path.

exit accesses, exits, and exit discharges are sufficiently remote to ensure, with reasonable certainty, that the same fire will not obstruct multiple egress routes. The exit separation is permitted by 7.5.1.3.3 to be reduced to one-third of the maximum overall diagonal measurement in fully sprinklered buildings, because the sprinkler system is expected to control the fire so that the use of multiple egress paths will not be lost.

Although existing buildings are exempted by the provision of 7.5.1.3.5 from the diagonal rule of 7.5.1.3.2 and 7.5.1.3.3, they must meet the remoteness requirement via the performance requirement of 7.5.1.3.1. Therefore, in existing buildings, remoteness is not required to be judged via the diagonal rule; it must be met via the provision of 7.5.1.3.1.

Exhibit 7.170 illustrates the provision of 7.5.1.3.4, which permits — for other than high-rise buildings — the distance between exit enclosures to be measured along a minimum 1-hour fire resistance-rated corridor with appropriate fire protection-rated door assemblies. Although the exit enclosures are physically closer to each other than the dimension measured along the corridor, the exits will behave, under fire conditions, as if they were the corridor length apart.

**7.5.1.4** Interlocking or scissor stairs shall comply with 7.5.1.4.1 and 7.5.1.4.2.

Exhibit 7.170

Exit remoteness measured along 1-hour-rated corridor.

**7.5.1.4.1** New interlocking or scissor stairs shall be permitted to be considered only as a single exit.

**7.5.1.4.2\*** Existing interlocking or scissor stairs shall be permitted to be considered separate exits, provided that they meet all of the following criteria:

- (1) They are enclosed in accordance with 7.1.3.2.
- (2) They are separated from each other by 2-hour fire resistance-rated noncombustible construction.
- (3) No protected or unprotected penetrations or communicating openings exist between the stair enclosures.

**A.7.5.1.4.2** It is difficult in actual practice to construct scissor stairs so that products of combustion that have entered one stairway do not penetrate into the other. Their use as separate required exits is discouraged. The term *limited-combustible* is intentionally not included in 7.5.1.4.2. The user's attention is directed to the provisions for limited-combustible and noncombustible in 4.6.13 and 4.6.14, respectively.

New scissors stairs are restricted by 7.5.1.4.1 to serving only as a single exit, because it is nearly impossible to ensure that the fire-rated and smoke-resisting separations provided between the two entwined stairs are complete and will stay complete over the life of the building. For example, standpipes are run vertically through the scissor stairs so as to create openings that connect the two stair enclosures.

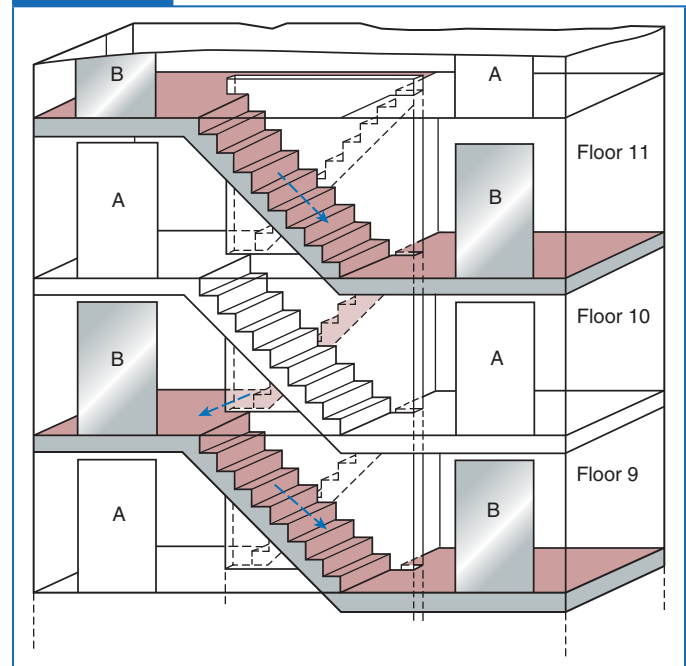

For existing installations, scissors stairs are regulated by 7.5.1.4.2 to ensure that they will perform similarly to two more widely-separated exit stairs under fire conditions. Some design professionals believe scissors stairs are hazardous and should not be permitted; others believe just the opposite. Generally, the principal objection is that scissors stairs cannot be reliably built to create an absolute barrier to the passage of fire, smoke, and

toxic gases between the stair enclosures. Even if such a barrier is created, there is still concern that settling of the building or exposure to fire conditions might result in the cracking of the separating walls, landings, and stair runs, which could allow fire, smoke, and gases to pass from one exit stair enclosure into its entwined neighbor. On the other hand, those who do not believe that scissors stairs present such problems point to their advantages in reducing construction costs and saving space.

Paragraph 7.5.1.4.2(2) requires existing scissors stairs to have noncombustible, 2-hour fire resistance-rated separating construction. Some form of masonry or poured concrete wall, landing, or stair run is normally used to meet the definition of *noncombustible material* (see 4.6.13). Although scissors stairs can be located with their entrances remote from one another and their discharges also remotely placed, the remoteness requirements are applicable to scissors stairs only if they are to be considered as separate exits. Where not sufficiently separated or not remote from each other — or in new construction — scissors stairs cannot be used as separate exits but can be considered as a single exit, with their combined egress width providing increased capacity over that of a single stair. These points are illustrated in Exhibit 7.171 and Exhibit 7.172.

In Exhibit 7.171, the two existing entwined stairways sharing the same enclosing walls are called scissors stairs. To be considered separate exits, the existing stairs must be completely separated from each other. In effect, each stair enclosure must consist of a fire resistance-rated tube entwined around the other stair in a form similar to a helix. This arrangement results in space and cost savings by permitting the stairs to share the common

Exhibit 7.171

Scissors stairs.

enclosing walls that separate them from the remainder of the building. With this arrangement, two independent escape paths are created, similar to those provided by two independent stair enclosures positioned at a distance from each other. The continuity of all walls provides a complete separation at all points. The arrows designate the direction of egress travel in Stair B.

**Exhibit 7.172** illustrates some of the advantages of scissors stairs versus conventional exit stairs. The two stairs, positioned at the center of the exhibit and highlighted by placement within the oval, are entwined to create a set of scissors stairs. They provide the same degree of remoteness as the separate and independent stairs shown by the dashed lines at the sides of the exhibit and encircled. Travel distance to either the scissors stairs or the independent stairs is equal, even if the independent exit stairs were to be relocated at the opposite corners (X) of the floor.

**7.5.1.5\*** Exit access shall be arranged so that there are no dead ends in corridors, unless permitted by, and limited to the lengths specified in, **Chapters 11** through **43**.

A dead end exists in a corridor where the corridor continues past an exit and creates a pocket into which an occupant might travel.

Scissors stairs contrasted with conventional exit stairs.

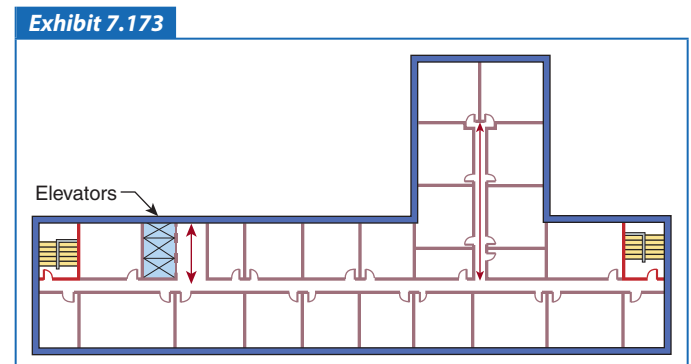

The occupant then recognizes there is no exit at that end of the pocket and is forced into retracing the original path to reach the exit. Although relatively short dead-end corridors are permitted for all occupancies by the chapter applicable to that occupancy, it is a better practice to avoid them; dead-end corridors increase the danger of people becoming trapped during a fire. Note that compliance with the limits on dead-end corridors does not necessarily mean that the requirements for remoteness of exits are met. Requirements for remoteness are especially difficult to meet in small buildings or buildings with short public corridors.

**Exhibit 7.173** illustrates examples of two common types of dead-end corridors. In moving toward exits, occupants from building spaces other than the rooms served by the dead-end portion of the corridor could mistakenly travel into the dead end. Similarly, any occupant of the floor might mistakenly travel into the dead end created by the elevator lobby, which is connected to the corridor so as not to be discerned by the occupants as being anything other than a corridor. Neither of the dead-end corridor pockets leads to an exit.

For persons occupying the two rooms located at the very end of the dead-end corridor section at the top of **Exhibit 7.173**, the travel from those rooms through this portion of the corridor system involves the concept of common path of travel, not dead-end corridors. Because the concepts of dead-end corridors and common path of travel are often confused, dead-end corridors have been blamed for fire deaths more correctly attributable to common path of travel problems. For example, the report on a 1977 Rhode Island dormitory fire in which 10 people died reads:

Dead-end corridors approximately 61 feet long existed at each end of the dormitory. These dead ends were allowed by the Rhode Island building code in effect at the time when the building renovations were made in 1972. . . . A factor contributing to four of the . . . deaths and several of the injuries was the long, dead-end corridor. Residents who left their rooms in this dead end were . . . [kept from reaching] their only exit.<sup>21</sup>

For the occupants of the other five rooms with door assemblies opening into the dead-end corridor section at the top of **Exhibit 7.173**, the concepts of both dead-end corridors and

Examples of common types of dead-end corridors.

common path of travel are applicable. Although occupants must travel in one direction to reach an exit, they also might mistakenly turn the wrong way when leaving their rooms and travel into the remainder of the dead-end corridor pocket, only to have to reverse direction and retrace their steps to reach an exit.

**A.7.5.1.5** The terms *dead end* and *common path of travel* are commonly used interchangeably. Although the concepts of each are similar in practice, they are two different concepts.

A common path of travel exists where a space is arranged so that occupants within that space are able to travel in only one direction to reach any of the exits or to reach the point at which the occupants have the choice of two paths of travel to remote exits. Part (a) of Figure A.7.5.1.5 is an example of a common path of travel.

While a dead end is similar to a common path of travel, a dead end can exist where there is no path of travel from an occupied space but can also exist where an occupant enters a corridor thinking there is an exit at the end and, finding none,

is forced to retrace his or her path to reach a choice of exits. Part (b) of Figure A.7.5.1.5 is an example of such a dead-end arrangement.

Combining the two concepts, part (c) of Figure A.7.5.1.5 is an example of a combined dead-end/common path of travel problem.

Common paths of travel and dead-end travel are measured using the same principles used to measure travel distance as described in Section 7.6. Starting in the room shown in part (d) of Figure A.7.5.1.5, measurement is made from the most remote point in the room, A, along the natural path of travel and through the doorway along the centerline of the corridor to point C, located at the centerline of the corridor, which then provides the choice of two different paths to remote exits; this is common path of travel. The space between point B and point C is a dead end. (See 3.3.47 for the definition of common path of travel.)

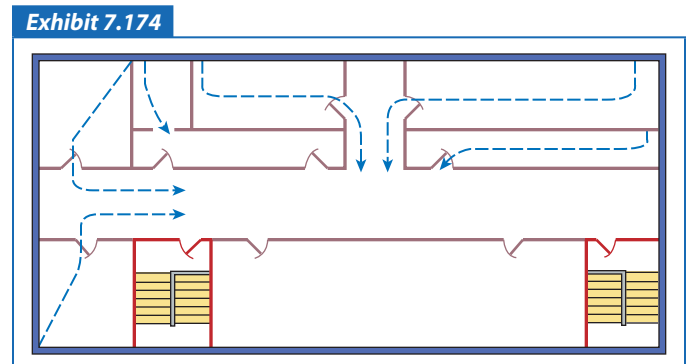

Common paths of travel are explained in A.7.5.1.5. The portion of the exit access travel to which an occupant is steered in one direction only without the option of traveling in another independent direction toward an exit is common path of travel (see definition in 3.3.47). Exhibit 7.174 shows examples of common paths of travel (illustrated by the dashed lines). In each case illustrated, an occupant is steered in only one direction before reaching a point at which travel in independent directions becomes possible. Common path of travel might exist only within rooms and occupied spaces, or it might exist within the combination of room space and corridors.

Part (a) of Exhibit 7.175 depicts the extent of three dead-end corridor pockets. In Part (b), the dashed lines illustrate the numerous common paths of travel.

Note that the common paths of travel shown by the dashed lines in Part (b) of Exhibit 7.175 are meant to include travel around all obstacles, such as furniture. Where furniture placement is not known, common path and travel distance are typically evaluated assuming an occupant has to traverse a distance equal to the length plus the width of the room in order to reach the door opening. Common path of travel measurement shares some common guidelines with travel distance measurement. See the commentary following A.7.6.1.

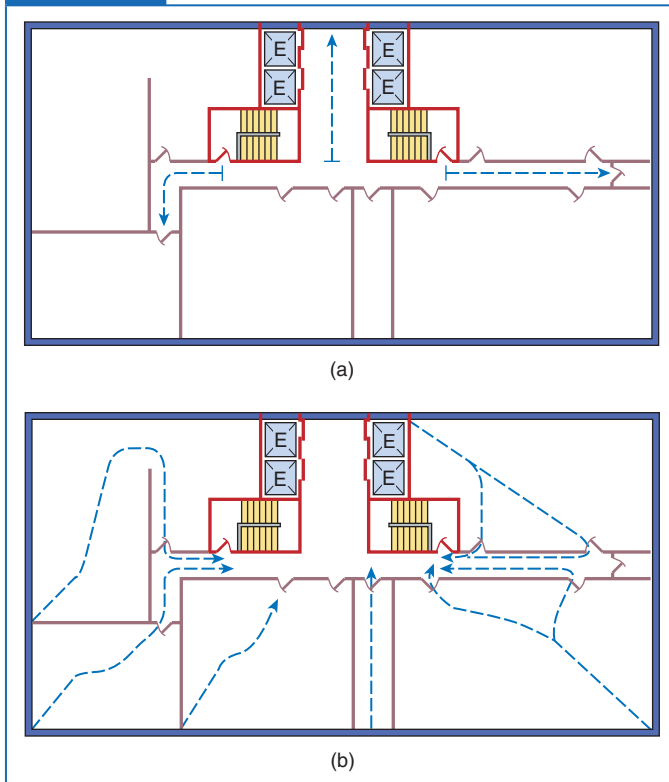

**Figure A.7.5.1.5** Common Paths of Travel and Dead-End Corridors.

**Exhibit 7.174** Common paths of travel.

Exhibit 7.175

Dead-end corridors and common paths of travel.

**7.5.1.6** Exit access from rooms or spaces shall be permitted to be through adjoining or intervening rooms or areas, provided that such rooms or areas are accessory to the area served. Foyers, lobbies, and reception rooms constructed as required for corridors shall not be construed as intervening rooms. Exit access shall be arranged so that it is not necessary to pass through any area identified under Protection from Hazards in **Chapters 11** through **43**.

**Paragraph 7.5.1.6** permits exit access travel through adjoining spaces if such spaces are accessory to the area served and such travel is not through any area identified under protection from hazards in an occupancy chapter (generally subsection \_\_.3.2). **Exhibit 7.176** illustrates exit access travel through intervening spaces that are under the control of the tenant and are not hazardous. Even though the hazardous contents storage room is under the control of the occupants of tenant space A, the hazard makes passage through the room unsafe. Passage from tenant space A into tenant space B is not permitted, because there is no assurance that the door assembly into tenant space B will be left unlocked, unblocked, and usable to occupants of tenant space A.

**7.5.2 Impediments to Egress.** See also **7.1.9** and **7.2.1.5**.

**7.5.2.1\*** Access to an exit shall not be through kitchens, store-rooms other than as provided in **Chapters 36** and **37**, restrooms, closets, bedrooms or similar spaces, or other rooms or spaces

Exhibit 7.176

Exit access through adjoining rooms.

subject to locking, unless passage through such rooms or spaces is permitted for the occupancy by **Chapter 18, 19, 22, or 23**.

**A.7.5.2.1** It is not the intent that an area with equipment such as a beverage brewpot, microwave oven, and a toaster be considered a kitchen.

**Paragraph 7.5.2.1**, in combination with **7.5.1.6**, prevents exit access from passing through certain rooms either due to increased relative hazard or potential blockage or locking. The text of **A.7.5.2.1** clarifies that the presence of beverage brewpots, microwave ovens, and toasters, commonly found in employee break areas that often are located in spaces not separated from the remainder of an open floor plan, do not cause such spaces to be classified as kitchens through which **7.5.1.6** and **7.5.2.1** restrict exit access.

**7.5.2.2\*** Exit access and exit doors shall be designed and arranged to be clearly recognizable.

**A.7.5.2.2** Doors that lead through wall paneling, and that harmonize in appearance with the rest of the wall to avoid detracting from some desired aesthetic or decorative effect, are not acceptable, because casual occupants might not be aware of such means of egress even though it is visible.

**7.5.2.2.1** Hangings or draperies shall not be placed over exit doors or located so that they conceal or obscure any exit, unless otherwise provided in **7.5.2.2.2**.

**7.5.2.2.2** Curtains shall be permitted across means of egress openings in tent walls, provided that all of the following criteria are met:

- (1) They are distinctly marked in contrast to the tent wall so as to be recognizable as means of egress.
- (2) They are installed across an opening that is at least 6 ft (1830 mm) in width.
- (3) They are hung from slide rings or equivalent hardware so as to be readily moved to the side to create an unobstructed opening in the tent wall that is of the minimum width required for door openings.

See the commentary following [A.7.1.10.1](#) for more information on maintaining means of egress free of obstructions or impediments.

### 7.5.3 Exterior Ways of Exit Access.

The provisions of [7.5.3](#) apply to exit access in the typical motel arrangement where exit access from the guest rooms is provided by door openings to an open-air exit access balcony to an open stair. This arrangement is also common in apartment buildings and office buildings in warm climates. An understanding of these provisions is important, because many of the exemptions from the mandatory sprinkler requirements for the various residential occupancies conditionally apply where exterior exit access is provided.

**7.5.3.1** Exit access shall be permitted to be by means of any exterior balcony, porch, gallery, or roof that conforms to the requirements of this chapter.

**7.5.3.2** The long side of the balcony, porch, gallery, or similar space shall be at least 50 percent open and shall be arranged to restrict the accumulation of smoke.

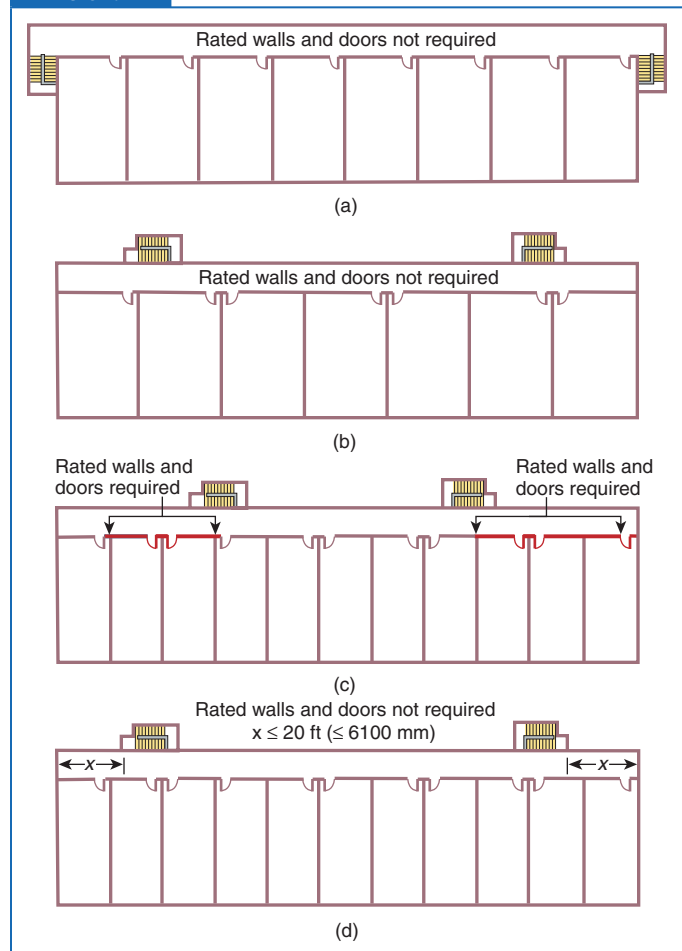

Exterior ways of exit access need significant openings to the exterior so as not to become smoke-logged and unusable. [Paragraph 7.5.3.2](#) establishes that at least 50 percent of the long side of the balcony, porch, gallery, or similar space is required to be open.

**7.5.3.3** Exterior exit access balconies shall be separated from the interior of the building by walls and opening protectives as required for corridors, unless the exterior exit access balcony is served by at least two remote stairs that can be accessed without any occupant traveling past an unprotected opening to reach one of the stairs, or unless dead ends on the exterior exit access do not exceed 20 ft (6100 mm).

[Paragraph 7.5.3.3](#) requires the exterior exit access to be protected by separating construction from the interior of the building via the same rules that are applicable to corridors. However, this requirement does not apply to exit access served by at least two remote stairs, as detailed. Such an arrangement is used more often than the rated construction required by [7.5.3.3](#). To use this arrangement, access must be possible to both of the required remote stairs, one of which must be reachable without traveling past an unprotected opening.

[Exhibit 7.177](#) illustrates four arrangements permitted by [7.5.3.3](#). In Part (a) and Part (b), it is possible for occupants of all rooms to reach one of the stairs without having to travel past any opening from which fire might issue; thus, fire-rated walls and door assemblies are not required. In Part (c), the occupants of rooms at the ends of the building must travel past other rooms to reach a stair; thus, fire resistance-rated walls and fire protection-rated opening protectives, such as windows and door assemblies, are required in the areas indicated.

**Exhibit 7.177**

*Exterior ways of exit access.*

In Part (d), the alternative of [7.5.3.3](#), related to limiting the length of the exit access balcony dead end, is used to exempt the fire-rated wall construction and fire-rated opening protectives along the exterior exit access path. Provided that the exit access balcony dead end, denoted by the distance X, does not exceed 20 ft (6100 mm), the occupant using the exterior exit access will not be exposed to an excessive number of unprotected openings.

**7.5.3.4** Exterior exit access shall be arranged so that there are no dead ends in excess of those permitted for dead-end corridors in [Chapters 11](#) through [43](#).

Because [7.5.3.3](#) permits unrated construction along a maximum 20 ft (6100 mm) dead-end exterior exit access path, it seems logical to recognize longer dead ends, as permitted by some of the occupancy chapters, where the exterior exit access path is protected by rated walls and rated opening protectives.

## 7.5.4 Accessible Means of Egress.

**7.5.4.1\*** Areas accessible to people with severe mobility impairment, other than in existing buildings, shall have not less than two accessible means of egress, unless otherwise provided in 7.5.4.1.2 through 7.5.4.1.4.

**A.7.5.4.1** An accessible means of egress should comply with the accessible route requirements of ICC/ANSI A117.1, *American National Standard for Accessible and Usable Buildings and Facilities*.

**7.5.4.1.1** Access within the allowable travel distance shall be provided to not less than one accessible area of refuge or one accessible exit providing an accessible route to an exit discharge.

**7.5.4.1.2** A single accessible means of egress shall be permitted from buildings or areas of buildings permitted to have a single exit.

**7.5.4.1.3** Accessible means of egress shall not be required in health care occupancies protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7.

**7.5.4.1.4** Exit access travel along the accessible means of egress shall be permitted to be common for the distances permitted as common paths of travel.

Paragraph 7.5.4.1 requires that, in other than existing buildings, accessible means of egress be provided for all areas accessible to persons with severe mobility impairment. The term *accessible means of egress* is defined in 3.3.172.1 as “a means of egress that provides an accessible route to an area of refuge, a horizontal exit, or a public way.” The term *severe mobility impairment* is defined in 3.3.246 as “the ability to move to stairs but without the ability to use the stairs.”

For a single-story building with typical exit door assemblies to the exterior at finished ground level (grade), the requirement for accessible means of egress is normally met without having to provide any additional features. For a multistory building involving vertical travel to ground, the requirement for accessible means of egress from the upper floors might be met by providing ramps. Because ramp systems use considerable space, the requirement for accessible means of egress from the upper floors will most often be met by providing areas of refuge meeting the requirements of 7.2.12.

Exhibit 7.178 illustrates arrangements providing accessible means of egress. In Part (a) and Part (b), accessible means of egress are provided via finished ground level door assemblies or ramps from the second story.

In Part (c), areas of refuge with rated barrier and extra-width stairs in accordance with 7.2.12 provide accessible means of egress. In Part (d), the floor of a fully sprinklered building with a second accessible room on the floor creates an area of refuge via

Exhibit 7.178

Accessible means of egress.

the definition in 3.3.22, which provides, via the two stairs and the help of emergency responders, two accessible means of egress paths.

The Code does not require areas of refuge; it requires accessible means of egress. The easiest way to meet the requirements for accessible means of egress in multistory buildings is by providing areas of refuge. See 7.2.12 and its associated commentary.

**Paragraph 7.5.4.1** clarifies that the requirement for accessible means of egress is not retrospectively required in existing buildings, unless specifically required by the applicable occupancy chapter.

Note that **7.5.4.1** requires a minimum of two accessible means of egress, unless one of the exceptions of **7.5.4.1.2** or **7.5.4.1.3** is met. Assume that the buildings depicted in **Exhibit 7.178** are classified as other than health care occupancies, so that the exemption offered by **7.5.4.1.3** does not apply. Assume also that the \_\_\_\_2.4 subsection of the applicable occupancy chapter does not permit a single means of egress and, therefore, the exemption offered by **7.5.4.1.2** does not apply. Part (a), Part (b), and Part (c) depict floors with two accessible means of egress.

Part (d) depicts a single area of refuge with access to two exits. The intent of **7.2.12.1** is that the sprinkling of the building and the presence of two exits create two accessible means of egress once emergency responders arrive to assist in the evacuation of the person with severe mobility impairment. Persons with severe mobility impairment are able to await rescue assistance in tenable conditions until emergency responders arrive. The two exit stair enclosures, although not of the minimum width addressed in **7.2.12.2.3**, provide sufficient width for emergency responders to carry the occupant on the stair to finished grade level, albeit at a slow pace. The sprinklers are expected to control the fire to permit the exit stair enclosures to be used well into the fire. If one of the exit stair enclosures is not usable, the other provides an alternative route. Taken together, the features provided in the sprinklered building (including the communication system required at the elevator landing by **7.2.12.1.1**) serve to provide two accessible means of egress. The *Code* text of **7.5.4** and **7.2.12** does not clearly explain this concept.

**Paragraph 7.5.4.1.4** does not permit a single accessible means of egress; rather, it permits that, where two accessible means of egress are required, travel is permitted to be along a single accessible path that is not longer than the distance permitted as common path of travel before travel along two separate accessible paths must become available.

**7.5.4.2** Where two accessible means of egress are required, the exits serving such means of egress shall be located at a distance from one another not less than one-half the length of the maximum overall diagonal dimension of the building or area to be served. This distance shall be measured in a straight line between the nearest edge of the exit doors or exit access doors, unless otherwise provided in **7.5.4.2.1** through **7.5.4.2.3**.

**Paragraph 7.5.4.2** establishes criteria for judging the remoteness of exits serving accessible means of egress paths. It is analogous to **7.5.1.3.2**, which establishes remoteness for means of egress using the one-half diagonal rule in nonsprinklered buildings. See **A.7.5.1.3.2**.

**7.5.4.2.1** Where exit enclosures are provided as the required exits specified in **7.5.4.2** and are interconnected by not less than a 1-hour fire resistance-rated corridor, exit separation shall be permitted to be measured along the line of travel within the corridor.

**7.5.4.2.2** The requirement of **7.5.4.2** shall not apply to buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with **Section 9.7**.

**7.5.4.2.3** The requirement of **7.5.4.2** shall not apply where the physical arrangement of means of egress prevents the possibility that access to both accessible means of egress will be blocked by any one fire or other emergency condition as approved by the authority having jurisdiction.

**7.5.4.3** Each required accessible means of egress shall be continuous from each accessible occupied area to a public way or area of refuge in accordance with **7.2.12.2.2**.

**Exhibit 7.179** shows exit discharge that does not provide an accessible route due to the step-down that might prevent a person with severe mobility impairment from traveling to the sidewalk. The step prevents an accessible route from continuing to the public way. **Exhibit 7.180** shows exit discharge that continues the accessible route, via a ramp, to the sidewalk and then to the public way.

**7.5.4.4** Where an exit stair is used in an accessible means of egress, it shall comply with **7.2.12** and either shall incorporate an area of refuge within an enlarged story-level landing or shall be accessed from an area of refuge.

**7.5.4.5** To be considered part of an accessible means of egress, an elevator shall be in accordance with **7.2.12.2.4**.

**Exhibit 7.179**

*Step at front door that prevents accessible route from continuing to public way. (Photo courtesy of Jake Pauls)*

Exhibit 7.180

Ramp at front door that permits accessible route to continue to public way. (Photo courtesy of Jake Pauls)

**7.5.4.6** To be considered part of an accessible means of egress, a smoke barrier in accordance with [Section 8.5](#) with not less than a 1-hour fire resistance rating, or a horizontal exit in accordance with [7.2.4](#), shall discharge to an area of refuge in accordance with [7.2.12](#).

**7.5.4.7** Accessible stories that are four or more stories above or below a story of exit discharge shall have not less than one elevator complying with [7.5.4.5](#), except as modified in [7.5.4.8](#).

**7.5.4.8** Where elevators are required by [7.5.4.7](#), the smokeproof enclosure required by [7.2.12.2.4](#) shall not be required in buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with [9.7.1.1\(1\)](#).

**7.5.4.9** An area of refuge used as part of a required accessible means of egress shall be in accordance with [7.2.12](#).

Where it might be necessary to carry persons and their wheelchairs on stairs for four or more stories to the ground level, the provision of [7.5.4.7](#) requires at least one elevator complying with [7.5.4.5](#), which imposes special elevator features and protection in accordance with [7.2.12.2.4](#). However, if automatic sprinklers protect the building throughout, the elevator shaft system is exempted by [7.5.4.8](#) from the smokeproof enclosure

requirement of [7.2.12.2.4\(3\)](#). This is consistent with the premise that sprinklers control fires so as to limit smoke production.

[Paragraph 7.5.4.9](#) completes the package by requiring areas of refuge used as part of accessible means of egress to follow the detailed criteria for areas of refuge presented in [7.2.12](#).

## 7.6\* Measurement of Travel Distance to Exits

**A.7.6** [Table A.7.6](#) is a compilation of the requirements of the individual occupancy chapters ([Chapters 12](#) through [42](#)) for permissible length of common path of travel, dead-end corridors, and travel distance to not less than one of the required exits.

A dead end exists where an occupant enters a corridor thinking there is an exit at the end and, finding none, is forced to retrace the path traveled to reach a choice of egress travel paths. Although relatively short dead ends are permitted by this *Code*, it is better practice to eliminate them wherever possible, as they increase the danger of persons being trapped in case of fire. Compliance with the dead-end limits does not necessarily mean that the requirements for remoteness of exits have been met. Such lack of compliance is particularly true in small buildings or buildings with short public hallways. Adequate remoteness can be obtained in such cases by further reducing the length of dead ends. (See also [A.7.5.1.5](#).)

The *Code* specifies the maximum distance that occupants are permitted to travel from their position in a building to the nearest exit. There is no formula by which this distance can be established.

Maximum allowed travel distances are based on factors that include the following:

1. Number, age, and physical condition of building occupants and the rate at which they can be expected to move
2. Type and number of obstructions (e.g., display cases, seating, heavy machinery) around which occupants must travel
3. Number of people in any room or space and the distance from the farthest point in that room to the door opening
4. Amount and nature of combustibles expected in a particular occupancy
5. Rapidity with which fire might spread (a function of type of construction, materials used, degree of compartmentation, and presence or absence of automatic fire detection and extinguishing systems)

Allowable travel distances will vary with the type and size of occupancy and the degree of hazard present. [Table A.7.6](#) is an aggregation of the maximum travel distance allowances specified elsewhere in the *Code*, typically from the [\\_\\_\\_2.6](#) subsection of each occupancy chapter. As shown in [Table A.7.6](#), maximum travel distances can vary from 75 ft (23 m) in nonsprinklered high

Table A.7.6 Common Path, Dead-End, and Travel Distance Limits (by occupancy)

hazard storage occupancies to 400 ft (120 m) in sprinklered mall buildings or sprinklered special-purpose industrial occupancies meeting additional criteria. For most occupancies, the allowable travel distance is permitted to be increased if the building is protected throughout by automatic sprinkler systems.

Where the occupant has been provided with at least two paths of travel to an exit, it becomes important that the time needed to travel the shorter of the two paths is not so great as to place the occupant in further danger. There are no formulae or exact criteria for determining maximum permitted travel

NR: No requirement. NA: Not applicable.

<sup>a</sup>For common path serving >50 persons, 20 ft (6.1 m); for common path serving ≤50 persons, 75 ft (23 m).

<sup>b</sup>Dead-end corridors of 20 ft (6.1 m) permitted; dead-end aisles of 20 ft (6.1 m) permitted.

<sup>c</sup>See Chapters 12 and 13 for special considerations for smoke-protected assembly seating in arenas and stadia.

<sup>d</sup>This dimension is for the total travel distance, assuming incremental portions have fully utilized their permitted maximums. For travel distance within the room, and from the room exit access door to the exit, see the appropriate occupancy chapter.

<sup>e</sup>See 19.2.5.2.

<sup>f</sup>See business occupancies, Chapters 38 and 39.

<sup>g</sup>See Chapter 23 for special considerations for existing common paths.

<sup>h</sup>This dimension is from the room/corridor or suite/corridor exit access door to the exit; thus, it applies to corridor common path.

<sup>i</sup>See the appropriate occupancy chapter for requirements for second exit access based on room area.

<sup>j</sup>See the appropriate occupancy chapter for special travel distance considerations for exterior ways of exit access.

<sup>k</sup>See 36.4.4 and 37.4.4 for special travel distance considerations in covered malls considered to be pedestrian ways.

<sup>l</sup>See Chapters 38 and 39 for special common path considerations for single-tenant spaces.

<sup>m</sup>See Chapters 40 and 42 for special requirements on spacing of doors in aircraft hangars.

<sup>n</sup>See Chapter 40 for industrial occupancy special travel distance considerations.

<sup>o</sup>See Chapters 40 and 42 for special requirements if high hazard conditions exist.

<sup>p</sup>See 42.8.2.6.2 for special travel distance considerations in open parking structures.

distances. Many factors have been considered and weighed in establishing these distances; they are the result of observing people who are in motion, consensus judgment, and many years of studying the results of fires in which the pre-fire conditions of a building were known.

Excessive travel distances can be a factor in large losses of life in fires, because they increase the time required to reach the safety of an exit, whether the exit is a door assembly directly to the outside or into a properly enclosed exit stair on an upper floor of a building. There is evidence that excessive travel

distances played a role in a number of the fatalities on the casino floor at the MGM Grand Hotel fire in Las Vegas in 1980.<sup>22</sup> Of the 85 fatalities, 18 victims were located on the casino level, and some apparently were overrun by the flame front.

**7.6.1\*** The travel distance to an exit shall be measured on the floor or other walking surface as follows:

- (1) Along the centerline of the natural path of travel, starting from the most remote point subject to occupancy
- (2) Curving around any corners or obstructions, with a 12 in. (305 mm) clearance therefrom
- (3) Terminating at one of the following:
  - (a) Center of the doorway
  - (b) Other point at which the exit begins
  - (c) Smoke barrier in an existing detention and correctional occupancy as provided in [Chapter 23](#)

**A.7.6.1** The natural exit access (path of travel) is influenced by the contents and occupancy of the building. Furniture, fixtures, machinery, or storage can serve to increase the length of travel. It is good practice in building design to recognize the influence of contents and occupancy by spacing exits for a completely open floor area at closer intervals than are required, thus reducing the hazard of excessive travel distances due to the introduction of furniture, fixtures, machinery, or storage and minimizing the possibility of violating the travel distance requirements of this Code.

**Exhibit 7.181** illustrates the path along which travel distance to an exit is measured. In Part (a), the stair is not appropriately enclosed to qualify as an exit; second-floor travel distance measurement continues to the first floor at the exit door opening to the outside. In Part (b), the stair is properly enclosed and constitutes an exit; travel distance measurement ends on the second floor at the entrance door opening to the exit stair enclosure. The travel paths marked as 1 through 6 show that travel distance is measured as follows:

1. Starting at the most remote point subject to occupancy
2. On the floor or other walking surface
3. Along the centerline of the natural path of travel
4. Around corners and obstructions with a clearance of 12 in. (305 mm)
5. Over open exit access ramps and open exit access stairs in the plane of tread nosings
6. Ending where the exit begins

Travel distance is that length of travel to an exterior exit door opening [as shown in [Exhibit 7.181](#), Part (a)], an enclosed exit stair [as shown in [Exhibit 7.181](#), Part (b)], an exit passageway, or a horizontal exit. It includes all travel within the occupied space until an occupant reaches that level of protection afforded by the nearest exit. Therefore, where stairs form part of an exit access rather than an exit, the travel over such stairs is included in the travel distance measurement [as shown in [Exhibit 7.181](#), Part (a)].

**Exhibit 7.181**

*Measuring travel distance to an exit.*

The measurement of travel distance along stairs, as detailed in [7.6.4](#), is to be made in the plane of the tread nosings, not along each riser and tread. This measurement is illustrated in [Exhibit 7.182](#).

In reviewing plans for compliance with the travel distance limitations established for any occupancy, it is important to know the natural path of travel and the obstacles that are present. In [Exhibit 7.183](#), Part (a) and Part (b), depict the same building. In Part (a), points X and Y are located at the same physical distance from the nearest exit door opening. Without further information related to the layout of furniture and partitions, it isn't clear whether the occupant will be able to travel in a straight line, as shown from point Y to the exit door opening, or will need to follow a longer travel path that zigzags around obstacles, as shown from point X to the exit door opening. A prudent designer, with lack of knowledge about the actual placement of furniture and partitions, will not assume that travel distance is a straight-line measurement. Rather, the prudent designer would estimate

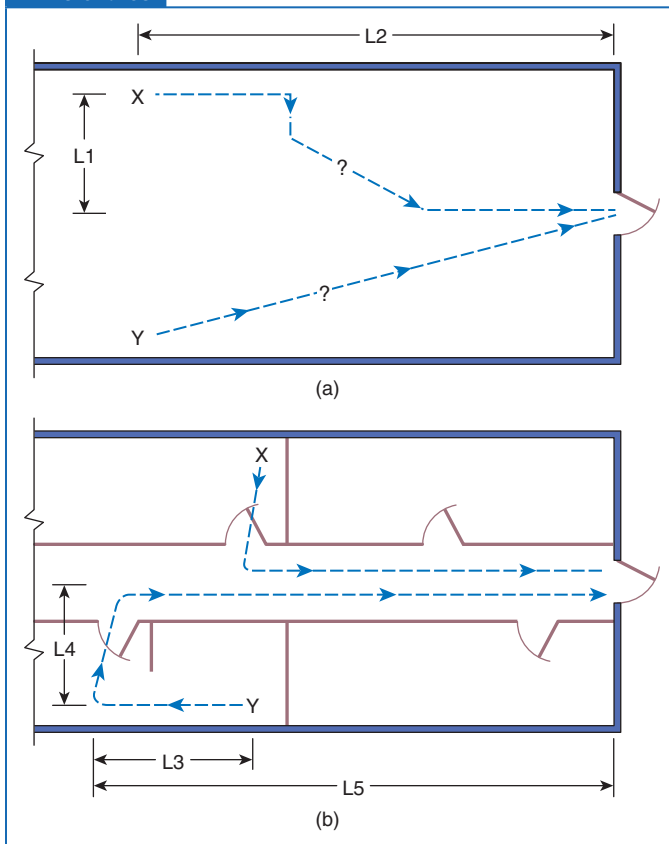

**Exhibit 7.182**

*Measuring travel distance on stairs.*

Exhibit 7.183

Measuring travel distance along the natural path of travel.

the travel distance to be at least the distance calculated by adding travel path segments L1 and L2.

In Exhibit 7.183, Part (b), the placement of partitions appears on the plan. An occupant is unable to travel in a straight “beeline” path to the exit door opening from either point X or point Y; the partitions preclude this. Further, the occupant at point Y must first move in a direction opposite from that of the building’s exit door opening to reach the room door opening before turning and traveling in a direction toward the exit door opening. In this case, the travel distance is calculated by adding together travel path segments L3, L4, and L5.

**7.6.2** Where outside stairs that are not separated from the building are permitted as required exits, the travel distance shall be measured from the most remote point subject to occupancy to the leading nosing of the stair landing at the floor level under consideration.

The provision of 7.6.2 was new to the 2012 edition of the Code. The provisions of 7.2.2.6.3.1 (1), (2), (3), and (5) exempt outside stairs from having to be separated by fire resistance-rated construction from the building. As explained in A.7.2.2.6.3.1, the stair is permitted to be considered an exit rather than exit access. Paragraph 7.6.2 clarifies the point to which travel distance must

be measured for such an exit stair. It is not clear whether the 10 ft (3050 mm) distance addressed in 7.6.4 must also be satisfied in order to permit the travel distance measurement to end at the stair landing. The provisions of 7.2.2.6.3.1, A.7.2.2.6.3.1, 7.6.2, and 7.6.4 need to be correlated for a future edition of the Code.

**7.6.3\*** Where open stairways or ramps are permitted as a path of travel to required exits, the distance shall include the travel on the stairway or ramp and the travel from the end of the stairway or ramp to an outside door or other exit in addition to the distance traveled to reach the stairway or ramp.

**A.7.6.3** Examples of locations where open stairways might exist include between mezzanines or balconies and the floor below.

**7.6.4** Where any part of an exterior exit is within 10 ft (3050 mm) of horizontal distance of any unprotected building opening, as permitted by 7.2.2.6.3 for outside stairs, the travel distance to the exit shall include the length of travel to the finished ground level.

The intent of 7.6.4 is to clarify that, if the exterior stair is exposed to unprotected building openings within 10 ft (3050 mm) horizontal distance, it is not considered an exit but is considered exit access; the travel distance, therefore, includes the measurement along the stair. The concept is illustrated in Exhibit 7.184. The openings in the wall that separates the rooms from the exit access balcony are not required to be fire rated in accordance with 7.5.3.3 (see the commentary that follows 7.5.3.3). Exterior Stair 1 is less than 10 ft (3050 mm) from the unprotected building openings (dimension d1). It cannot be considered an exit stair but, rather, an exit access stair in accordance with 7.6.4. The travel distance from point x must be measured to the bottom of the stair. Exterior Stair 2 is positioned 10 ft (3050 mm) from the unprotected building openings (dimension d2). It can be considered an exit in accordance with 7.6.4. The travel distance from point y needs to be measured only to the point on the stair landing that is 10 ft (3050 mm) from the unprotected exterior wall.

**7.6.5** Where measurement includes stairs, the measurement shall be taken in the plane of the tread nosing.

Exhibit 7.184

Measuring travel distance with egress paths that include exterior stairs.

**7.6.6** The travel distance in any occupied space to not less than one exit, measured in accordance with 7.6.1 through 7.6.5, shall not exceed the limits specified in this *Code*. (See 7.6.7.)

The maximum permitted travel distance is that length of travel path that must not be exceeded to reach the nearest exit. Although more than one exit might be required, the travel distance to exits other than the closest exit is not regulated.

**7.6.7** Travel distance limitations shall be as provided in Chapters 11 through 43 and, for high hazard areas, shall be in accordance with Section 7.11.

Although Section 7.6 establishes the method for measuring travel distance, it does not set the maximum travel distance permitted for a specific occupancy. Travel distance limitations are contained in other sections of the *Code*, typically the \_\_\_\_\_.2.6 subsection of Chapters 12 through 42. Travel distance limitations might be found in portions of the *Code* that are not occupancy chapters — for example, see 7.11.1 for special travel distance provisions applicable to areas with high hazard contents. The travel distance limitations specified in the occupancy chapters are summarized in Table A.7.6.

In the 1988 edition of the *Code*, the maximum permitted travel distances were increased in most occupancies to maintain the status quo, because an exemption was deleted that permitted the travel within small rooms or spaces to be excluded from the overall measurement of travel distance. This former provision exempted rooms that contained six or fewer people, and that had a travel distance within them of less than 50 ft (15 m), from being included in the overall travel distance measurement. Currently, travel distance measurement begins at the most remote point subject to occupancy as specified in 7.6.1(1).

## 7.7 Discharge from Exits

**7.7.1\* Exit Termination.** Exits shall terminate directly, at a public way or at an exterior exit discharge, unless otherwise provided in 7.7.1.2 through 7.7.1.4.

**A.7.7.1** An exit from the upper stories in which the direction of egress travel is generally downward should not be arranged so that it is necessary to change to travel in an upward direction at any point before discharging to the outside. A similar prohibition of reversal of the vertical component of travel should be applied to exits from stories below the floor of exit discharge. However, an exception is permitted in the case of stairs used in connection with overhead or underfloor exit passageways that serve the street floor only.

It is important that ample roadways be available from buildings in which there are large numbers of occupants so that exits will not be blocked by persons already outside. Two or more avenues of departure should be available for all but very small places. Location of a larger theater — for example, on a narrow

dead-end street — might be prohibited by the authority having jurisdiction under this rule, unless some alternate way of travel to another street is available.

Exterior walking surfaces within the exit discharge are not required to be paved and often are provided by grass or similar surfaces. Where discharging exits into yards, across lawns, or onto similar surfaces, in addition to providing the required width to allow all occupants safe access to a public way, such access also is required to meet the following:

- (1) Provisions of 7.1.7 with respect to changes in elevation
- (2) Provisions of 7.2.2 for stairs, as applicable
- (3) Provisions of 7.2.5 for ramps, as applicable
- (4) Provisions of 7.1.10 with respect to maintaining the means of egress free of obstructions that would prevent its use, such as snow and the need for its removal in some climates

**7.7.1.1** Yards, courts, open spaces, or other portions of the exit discharge shall be of the required width and size to provide all occupants with a safe access to a public way.

**7.7.1.2** The requirement of 7.7.1 shall not apply to interior exit discharge as otherwise provided in 7.7.2.

**7.7.1.3** The requirement of 7.7.1 shall not apply to rooftop exit discharge as otherwise provided in 7.7.6.

**7.7.1.4** Means of egress shall be permitted to terminate in an exterior area for detention and correctional occupancies as otherwise provided in Chapters 22 and 23.

The principle addressed in 7.7.1 is that, once a building occupant reaches an exit (the protected portion of the means of egress), the level of protection afforded by that exit cannot be reduced or eliminated. Therefore, except as noted, all exits must be continuous to a public way or other safe place or to an exit discharge that must, in turn, be continuous to the public way.

It is not sufficient to allow the egress system to terminate at the outside of a building, because there might not be enough space to provide safe movement away from the building. Also, the terminus of the egress system cannot be located at the outside in an enclosed court (see 3.3.50.1) from which travel back through the building might be necessary to get away from the building. In such a case, an exit passageway at least as wide as the exit itself, and constructed as specified for exits, is required to provide travel from the enclosed court to the safe place.

**7.7.2 Exit Discharge Through Interior Building Areas.** Exits shall be permitted to discharge through interior building areas, provided that all of the following are met:

- (1) Not more than 50 percent of the required number of exit stairs serving normally occupied areas of each floor, and not more than 50 percent of the exit stair capacity required for normally occupied areas of each floor, shall discharge through areas on any level of discharge, except as otherwise permitted by one of the following:
  - (a) One hundred percent of the exits shall be permitted to discharge through areas on any level of discharge in

detention and correctional occupancies as otherwise provided in [Chapters 22](#) and [23](#).

- (b) In existing buildings, the 50 percent limit on egress capacity shall not apply if the 50 percent limit on the required number of exits is met.
- (2) Each level of discharge shall discharge directly outside at the finished ground level or discharge directly outside and provide access to the finished ground level by outside stairs or outside ramps.
- (3) The interior exit discharge shall lead to a free and unobstructed way to the exterior of the building, and such way shall be readily visible and identifiable from the point of discharge from the exit
- (4) The interior exit discharge shall be protected by one of the following methods:
  - (a) The level of discharge shall be protected throughout by an approved automatic sprinkler system in accordance with [Section 9.7](#), or the portion of the level of discharge used for interior exit discharge shall be protected by an approved automatic sprinkler system in accordance with [Section 9.7](#) and shall be separated from the nonsprinklered portion of the floor by fire barriers with a fire resistance rating meeting the requirements for the enclosure of exits. (See [7.1.3.2.1](#).)
  - (b) The interior exit discharge area shall be in a vestibule or foyer that meets all of the following criteria:
    - i. The depth from the exterior of the building shall be not more than 10 ft (3050 mm), and the length shall be not more than 30 ft (9.1 m).
    - ii. The foyer shall be separated from the remainder of the level of discharge by fire barriers with a minimum 1-hour fire resistance rating, and existing installations of wired glass in steel frames shall be permitted to be continued in use.
    - iii. The foyer shall serve only as means of egress and shall include an exit directly to the outside.
- (5) The entire area on the level of discharge shall be separated from areas below by construction having a fire resistance rating not less than that required for the exit enclosure, unless otherwise provided in [7.7.2\(6\)](#).
- (6) Levels below the level of discharge in an atrium shall be permitted to be open to the level of discharge where such level of discharge is protected in accordance with [8.6.7](#).

The provisions of [7.7.2](#) were revised for the 2012 edition of the *Code* to permit exit discharge through the interior building area of any floor providing discharge from the building, not just the level of exit discharge.

The provisions of [7.7.2](#) permit a portion of the exit discharge from exit stairs to pass through interior building areas rather than discharge directly to the outside. Compliance with the criteria of [7.7.2](#) provides users of an exit stair enclosure that discharges through interior building areas with approximately the same level of protection offered to users of exit enclosures that discharge directly to the outside.

Among the questions most often asked regarding the *Code* are those that concern the requirements of [7.7.2\(4\)\(a\)](#) related to providing sprinkler protection on the level of discharge (i.e., the story on which the interior exit discharge occurs). The intent of [7.7.2\(4\)\(a\)](#) is to require sprinkler protection in the portion of the level of discharge that is used as interior exit discharge and to provide that portion of the level of discharge with fire-rated separation from all other portions of the level of discharge that are not sprinklered. The requirement of [7.7.2\(4\)\(a\)](#) can be met by either of the following means:

1. Protecting the entire level of discharge by automatic sprinklers; and separating the level of discharge from any floor below by fire-rated construction with the minimum fire rating required for the exit that discharges occupants though the level of discharge [see [7.1.3.2.1\(1\)](#) and (3)]

2. Providing automatic sprinkler protection in only that portion of the level of discharge used for interior exit discharge travel from the exit stair enclosure door opening to the door opening to the outside; separating the sprinklered portion of the level of discharge from the rest of the level of discharge by construction as required for the exit that discharges occupants though the level of discharge [again, see [7.1.3.2.1\(1\)](#) and (3)]; and separating the level of discharge from any floor below by fire-rated construction with the minimum fire rating required for the exit that discharges occupants though the level of discharge

An exemption to the sprinkler requirement of [7.7.2\(4\)\(a\)](#) is offered by [7.7.2\(4\)\(b\)](#) and involves providing a maximum 10 ft × 30 ft (3050 mm × 9.1 m) wired-glass foyer, which can be used only for egress and, thus, has no occupancy of its own.

Use of the 50 percent rule of [7.7.2](#) for discharge through the level of discharge is not dependent on occupancy permission; thus, it can be used in all occupancies. However, detention and correctional occupancies (see [22.2.7.3](#), [23.2.7.3](#), [22.2.7.4](#), and [23.2.7.4](#)) permit 100 percent of the exits and 100 percent of the egress capacity to discharge through the level of discharge. Hotels and dormitories establish additional requirements limiting the distance occupants are permitted to travel within their interior exit discharge through the level of discharge to the opening to the outside (see [28.2.7.3](#) and [29.2.7.3](#)).

[Exhibit 7.185](#) illustrates exit discharge arrangements meeting the requirements of [7.7.2](#). The equally sized stairs provide four required exits from the upper floors. Exit A discharges directly outside. Exit B is also considered to discharge directly outside, because its attached exit passageway affords protected passage to the door opening to the outside without leaving the protection offered by an exit. The other two Exits, C and D, are permitted to discharge across the first floor (the level of discharge), because they do not constitute more than 50 percent of the number of exits from an upper floor or more than 50 percent of the egress capacity of any upper floor. Exit C discharges into an area on the discharge level that is sprinklered and separated from the remainder of the floor and the basement, which are not sprinklered. The hourly fire resistance rating of the floor slab and

Exhibit 7.185

Exit discharge.

the separating fire barrier are the same as required for the enclosure of Exit C [e.g., a 2-hour rating if the stair is new and serves four or more stories in accordance with 7.1.3.2.1(3)]. Exit D discharges into a wired-glass foyer in the nonsprinklered portion of the floor in accordance with 7.7.2(4)(b).

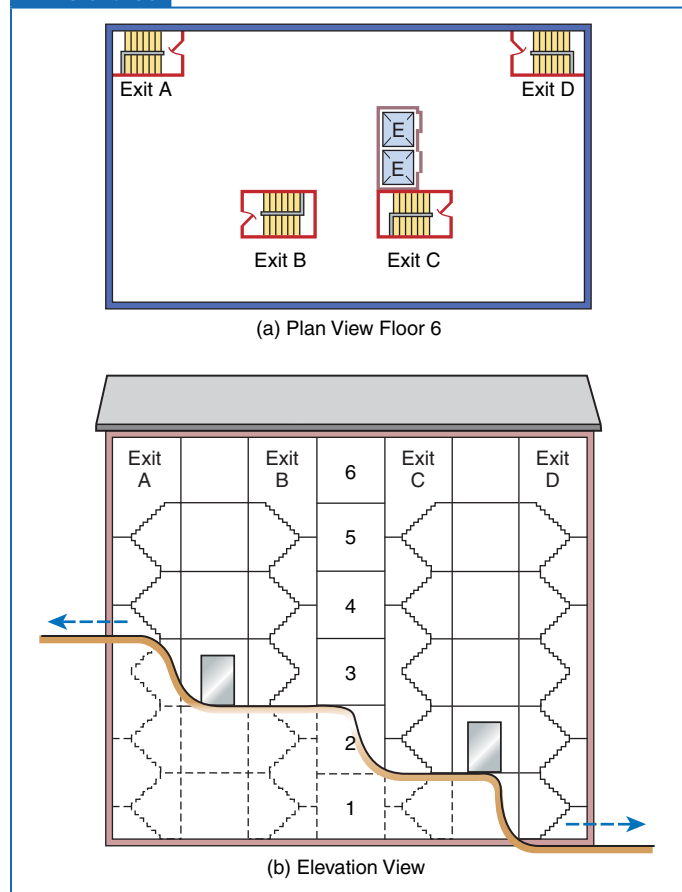

Exhibit 7.186 illustrates interior exit discharge on two floors. Four exits, all via exit stair enclosures, serve all six stories. In Part (a) of Exhibit 7.186, Exits A and D are located at exterior building walls, and Exits B and C are located away from exterior building walls. In Part (b), Exits A and D comprise 50 percent of the number of exits; provide 50 percent of the egress capacity for each floor; and discharge directly to the outside — Exit A at story 4, and Exit D at story 1. Exits B and C comprise 50 percent of the number of exits; provide 50 percent of the egress capacity for each floor; and discharge to interior areas — Exit B onto story 3, and Exit C onto story 2. Not more than 50 percent of the exits — both from a number of exits standpoint, and from a capacity of exits standpoint — discharges through interior building areas. Such interior exit discharge occurs on two floors, as this edition of the Code does not restrict interior exit discharge to being on only the level of exit discharge.

### 7.7.3 Arrangement and Marking of Exit Discharge.

**7.7.3.1** Where more than one exit discharge is required, exit discharges shall be arranged to meet the remoteness criteria of 7.5.1.3.

**7.7.3.2** The exit discharge shall be arranged and marked to make clear the direction of egress travel from the exit discharge to a public way.

Exhibit 7.186

Interior exit discharge on two stories.

**7.7.3.3\*** Stairs and ramps that continue more than one-half story beyond the level of discharge shall be provided with an approved means to prevent or dissuade occupants from traveling past the level of discharge during emergency building evacuation.

**A.7.7.3.3** Examples include partitions and gates. The design should not obstruct the normal movement of occupants to the exit discharge. Signs, graphics, or pictograms, including tactile types, might be permitted for existing exit enclosures where partitions or gates would obstruct the normal movement of occupants to the exit discharge.

The provision of 7.7.3.1 serves as a reminder that exit discharges, like exits and exit accesses, are required to be remote as addressed in 7.5.1.3.

The provision of 7.7.3.3 was revised for the 2012 edition of the Code. Earlier editions required the stair interruption to be provided by partitions, doors, or other effective means. The current language is performance-based and requires an approved means to dissuade occupants from traveling past the level of discharge during building emergency evacuation.

Exhibit 7.187 shows an exit stair landing at the level of discharge to the outside. The gate across the stair to the basement and the large directional exit arrow on the wall are intended to

Exhibit 7.187

Interruption of exit stair at level of discharge. (Photo courtesy of Jake Pauls)

minimize the possibility that occupants traveling on stairs will inadvertently continue their stair descent past the level of exit discharge (LED), stop at the basement level where the stair ends but where there is no discharge, and then have to reverse direction and retrace their steps to the level of discharge. The barrier needed to cue the occupant that the level of discharge has been reached might be a partition with door assembly, a gate, another physical barrier, signage, or floor marking that effectively interrupts the flow of travel, forcing a person to perform a deliberate act to continue traveling past the level of discharge, but not restricting required egress from floors below the level of discharge. Exhibit 7.188 shows the NO EXIT sign on the side of the gate facing the level of discharge floor landing.

**7.7.4 Components of Exit Discharge.** Doors, stairs, ramps, corridors, exit passageways, bridges, balconies, escalators, moving walks, and other components of an exit discharge shall comply with the detailed requirements of this chapter for such components.

**7.7.5 Signs.** See 7.2.2.5.4.

**7.7.6 Discharge to Roofs.** Where approved by the authority having jurisdiction, exits shall be permitted to discharge to roofs or other sections of the building or an adjoining building where all of the following criteria are met:

- (1) The roof/ceiling assembly construction has a fire resistance rating not less than that required for the exit enclosure.

Exhibit 7.188

Sign on gate providing interruption of exit stair. (Photo courtesy of Jake Pauls)

- (2) A continuous and safe means of egress from the roof is available.

An exit discharge to a roof is not acceptable, unless there is another continuous and safe means of egress from the roof and the roof construction affords protection against fire that is at least equivalent to that of the exit enclosure (e.g., the exit stair) that discharged occupants to the roof. Helicopter rescue from roofs is not dependable enough to be given credit as an exit; many factors in such a rescue are too unpredictable for this method to be a consideration.

Outside stairs leading to the roofs of other sections of the building or onto the roofs of adjoining buildings are acceptable as part of the means of egress, but only with the approval of the AHJ. The conditions and settings of such paths of travel are likely to be so varied that it is virtually impossible to cover them by written provisions. Ideally the AHJ judges each situation individually.

## 7.8 Illumination of Means of Egress

When fire occurs in a building, the degree of visibility in aisles, corridors, stairs, and exit passageways might mean the difference between orderly evacuation and chaos and, possibly, the difference between life and death.

### 7.8.1 General.

**7.8.1.1\*** Illumination of means of egress shall be provided in accordance with [Section 7.8](#) for every building and structure where required in [Chapters 11](#) through [43](#). For the purposes of this requirement, exit access shall include only designated stairs, aisles, corridors, ramps, escalators, and passageways leading to an exit. For the purposes of this requirement, exit discharge shall include only designated stairs, aisles, corridors, ramps, escalators, walkways, and exit passageways leading to a public way.

**A.7.8.1.1** Illumination provided outside the building should be to either a public way or a distance away from the building that is considered safe, whichever is closest to the building being evacuated.

The means of egress (i.e., exit access, exit, and exit discharge) encompasses practically all spaces where persons can be present. The subject addressed by [Section 7.8](#) is illumination of means of egress. It would seem that the title of [Section 7.8](#) indicates that such illumination needs to be provided throughout all portions of the exit access, the exit, and the exit discharge, but this is not so. Illumination is required throughout the exit (e.g., an enclosed exit stair or exit passageway). Yet, [7.8.1.1](#) clarifies that, for the purposes of applying the requirements of [Section 7.8](#), the portions of the exit access and exit discharge requiring illumination are only the “designated” egress paths, such as aisles, corridors, stairs, and ramps. “Designated” is meant to indicate designation by the authority having jurisdiction (AHJ). For example, most authorities having jurisdiction do not designate the space within an individual’s work cubicle as a portion of the exit access required to be illuminated, but the aisles serving multiple cubicles are typically designated as requiring illumination.

Illumination of means of egress is not required unless specifically called for in the appropriate occupancy chapter. However, all occupancy chapters do require illumination, but there are a few exemptions. For example, in new assembly occupancies, [12.2.8](#) exempts private-party tents not larger than 1200 ft<sup>2</sup> (112 m<sup>2</sup>) from the illumination requirement. Subsection [\\_\\_2.8](#) (e.g., [36.2.8](#) for new mercantile occupancies) of each occupancy chapter provides illumination requirements.

**7.8.1.2** Illumination of means of egress shall be continuous during the time that the conditions of occupancy require that the means of egress be available for use, unless otherwise provided in [7.8.1.2.2](#).

**7.8.1.2.1** Artificial lighting shall be employed at such locations and for such periods of time as are necessary to maintain the illumination to the minimum criteria values herein specified.

**7.8.1.2.2\*** Unless prohibited by [Chapters 11](#) through [43](#), automatic lighting control devices shall be permitted to temporarily turn off the illumination within the means of egress, provided that each lighting control device complies with all of the following:

- (1) In new installations, the lighting control device is listed.
- (2) The lighting control device is equipped to automatically energize the controlled lights upon loss of normal power and is evaluated for this purpose.

- (3) Illumination timers are provided and are set for a minimum 15-minute duration.
- (4) The lighting control device is activated by any occupant movement in the area served by the lighting units.
- (5) In new installations, the lighting control device is activated by activation of the building fire alarm system, if provided.
- (6) The lighting control device does not turn off any lights relied upon for activation of photoluminescent exit signs or path markers.
- (7) The lighting control device does not turn off any battery-equipped emergency luminaires, unit equipment, or exit signs.

**A.7.8.1.2.2** Photoluminescent materials and battery-powered luminaires require some period of time to restore themselves to full operational capacity after being de-energized.

Photoluminescent products rely on nearby luminaires to maintain their full capacity. When those luminaires are de-energized, the photoluminescent product will gradually deplete its capacity. Listed photoluminescent exit signs and path markers are restored to full rated capacity within one hour, and there is no known limit to the number of times they can be discharged and recharged, nor any known degradation of overall capacity or lifetime as a result of discharge/charge cycles.

De-energizing the normal (utility) power source will automatically begin the battery discharge cycle of emergency luminaires, unit equipment, and exit signs provided with battery backup. Once drained, these batteries will typically require between 24 and 72 hours, depending on the battery technology and charging circuitry design, to regain full capacity. Frequent discharge/charge cycles can reduce overall battery lifetime and, depending on battery technology, might also prematurely reduce overall battery capacity.

**7.8.1.2.3\*** Energy-saving sensors, switches, timers, or controllers shall be approved and shall not compromise the continuity of illumination of the means of egress required by [7.8.1.2](#).

**A.7.8.1.2.3** A consideration for the approval of automatic, motion sensor-type lighting switches, controls, timers, or controllers is whether the equipment is listed as a fail-safe device for use in the means of egress.

**7.8.1.3** The floors and other walking surfaces within an exit and within the portions of the exit access and exit discharge designated in [7.8.1.1](#) shall be illuminated as follows:

- (1) During conditions of stair use, the minimum illumination for new stairs shall be at least 10 ft-candle (108 lux), measured at the walking surfaces.
- (2) The minimum illumination for floors and other walking surfaces, other than new stairs during conditions of stair use, shall be to values of at least 1 ft-candle (10.8 lux), measured at the floor.
- (3) In assembly occupancies, the illumination of the walking surfaces of exit access shall be at least 0.2 ft-candle (2.2 lux)

during periods of performances or projections involving directed light.

- (4)\* The minimum illumination requirements shall not apply where operations or processes require low lighting levels.

**A.7.8.1.3(4)** Some processes, such as manufacturing or handling of photosensitive materials, cannot be performed in areas provided with the minimum specified lighting levels. The use of spaces with lighting levels below 1 ft-candle (10.8 lux) might necessitate additional safety measures, such as written emergency action plans, training of new employees in emergency evacuation procedures, and periodic fire drills.

The *Code* requires that there be at least 1 ft-candle (10.8 lux) of illumination at floor level.

**Paragraph 7.8.1.3(1)** requires at least 10 ft-candle (108 lux) for new stairs during conditions of stair use. Note that, during conditions where the stair is not being used but the building is occupied, there must be at least 1 ft-candle (10.8 lux) of illumination on the stair walking surfaces in compliance with **7.8.1.3(2)**. An arrangement that might be used to comply with **7.8.1.3(1)** and (2) would include illuminating the stair to a minimum of 1 ft-candle (10.8 lux) during periods that the building is occupied and using motion detectors to sense occupant presence in any portion of the stair enclosure that, upon activation, would increase the illumination level to the minimum 10 ft-candle (108 lux) requirement. **Exhibit 7.189** and **Exhibit 7.190** show novel lighting techniques — ensuring that stair treads are adequately illuminated and tread edges are easily discerned by stair users — for an outdoor stair and an indoor stair, respectively. **Exhibit 7.191** shows a stair with questionable illumination, especially given that occupants who use the stair in the downward direction are coming from the area near a building window wall with bright outdoor lighting.

When motion pictures, slides, and the like are being shown in theaters, auditoriums, and other assembly occupancies,

**Exhibit 7.189**

*Exterior stair illumination via lights in stair handrail. (Photo courtesy of Jake Pauls)*

**Exhibit 7.190**

*Interior stair illumination via lights at stair treads. (Photo courtesy of Jake Pauls)*

**Exhibit 7.191**

*Poorly lighted interior stair near brightly lit window space. (Photo courtesy of Jake Pauls)*

**7.8.1.3(3)** permits the level of illumination to be reduced to 0.2 ft-candle (2.2 lux).

**Paragraph 7.8.1.3(4)** recognizes that some operations (e.g., photographic film manufacturing) require low lighting levels. Special precautions can be taken for occupant life safety so as not to have to require a minimum illumination level.

**7.8.1.4\*** Required illumination shall be arranged so that the failure of any single lighting unit does not result in an illumination level of less than 0.2 ft-candle (2.2 lux) in any designated area.

**A.7.8.1.4** Failure of a lighting unit is deemed to have occurred when the light output drops below 70 percent of its original level.

All lights, circuits, or auxiliary power must be arranged to ensure continuity of egress lighting, although the performance level is permitted to decline from 1 ft-candle (10.8 lux) to 0.2 ft-candle (2.2 lux) if a system element fails. Continuity of egress lighting can be accomplished by means such as use of duplicate light bulbs in fixtures or overlapping light patterns from neighboring fixtures.

**7.8.1.5** The equipment or units installed to meet the requirements of [Section 7.10](#) also shall be permitted to serve the function of illumination of means of egress, provided that all requirements of [Section 7.8](#) for such illumination are met.

## 7.8.2 Sources of Illumination.

**7.8.2.1** Illumination of means of egress shall be from a source considered reliable by the authority having jurisdiction.

**7.8.2.2** Battery-operated electric lights and other types of portable lamps or lanterns shall not be used for primary illumination of means of egress. Battery-operated electric lights shall be permitted to be used as an emergency source to the extent permitted under [Section 7.9](#).

## 7.9 Emergency Lighting

### 7.9.1 General.

**7.9.1.1\*** Emergency lighting facilities for means of egress shall be provided in accordance with [Section 7.9](#) for the following:

- (1) Buildings or structures where required in [Chapters 11 through 43](#)
- (2) Underground and limited access structures as addressed in [Section 11.7](#)
- (3) High-rise buildings as required by other sections of this *Code*
- (4) Doors equipped with delayed-egress locks
- (5) Stair shafts and vestibules of smokeproof enclosures, for which the following also apply:
  - (a) The stair shaft and vestibule shall be permitted to include a standby generator that is installed for the smokeproof enclosure mechanical ventilation equipment.
  - (b) The standby generator shall be permitted to be used for the stair shaft and vestibule emergency lighting power supply.
- (6) New access-controlled egress doors in accordance with [7.2.1.6.2](#)

**A.7.9.1.1** Emergency lighting outside the building should provide illumination to either a public way or a distance away from the building that is considered safe, whichever is closest to the building being evacuated.

Emergency lighting is not required unless specifically called for in the appropriate occupancy chapter or by a provision of [7.9.1.1](#). Most occupancy chapters require emergency lighting in medium to large buildings. Subsection [7.9.1.1.2.9](#) of each occupancy chapter (e.g., [12.2.9](#) and [36.2.9](#) for new assembly and new mercantile occupancies, respectively) provides emergency lighting requirements.

**7.9.1.2** For the purposes of [7.9.1.1](#), exit access shall include only designated stairs, aisles, corridors, ramps, escalators, and passageways leading to an exit. For the purposes of [7.9.1.1](#), exit discharge shall include only designated stairs, ramps, aisles, walkways, and escalators leading to a public way.

The means of egress (i.e., exit access, exit, and exit discharge) encompasses practically all spaces where persons can be present. The subject addressed by [Section 7.9](#) is emergency lighting of means of egress. It would seem that the title of [Section 7.9](#) indicates that such emergency lighting needs to be provided throughout all portions of the exit access, the exit, and the exit discharge, but this is not so. Emergency lighting is required throughout the exit (e.g., in an enclosed exit stair or exit passageway). Yet, [7.9.1.2](#) clarifies that, for the purposes of applying the requirements of [Section 7.9](#), the portions of the exit access and exit discharge requiring emergency lighting are only the “designated” egress paths, such as aisles, corridors, stairs, and ramps. “Designated” is meant to indicate designation by the AHJ. For example, most authorities having jurisdiction do not designate the space within an individual’s work cubicle as a portion of the exit access required to be provided with emergency lighting, but the aisles serving multiple cubicles are typically designated as requiring emergency lighting.

**7.9.1.3** Where maintenance of illumination depends on changing from one energy source to another, a delay of not more than 10 seconds shall be permitted.

An on-site generator driven by a prime mover must be automatically started and capable of picking up the emergency lighting load within 10 seconds. If the generator is not able to supply power within this time frame, an auxiliary power source must be provided. For example, unit lighting packs with their integral batteries might be used to provide emergency lighting immediately upon loss of normal power, with a switchover to other lighting fixtures supplied by power from the generator at a later point in the incident during which normal power was lost.

Some turbine-driven emergency generators take longer than 10 seconds to reach operating speed. A backup battery pack, such as an uninterruptible power supply (UPS), capable of delivering emergency power for a few minutes might be used in conjunction with any on-site generator that cannot meet the 10-second requirement. As another alternative, unit lighting packs with their integral batteries might be used to provide emergency lighting immediately upon loss of normal power, with a switchover to other lighting fixtures supplied by power from the generator at a later point in the incident during which normal power was lost.

## 7.9.2 Performance of System.

**7.9.2.1** Emergency illumination shall be provided for a minimum of 1½ hours in the event of failure of normal lighting.

**7.9.2.1.1** Emergency lighting facilities shall be arranged to provide initial illumination that is not less than an average of 1 ft-candle (10.8 lux) and, at any point, not less than 0.1 ft-candle (1.1 lux), measured along the path of egress at floor level.

**7.9.2.1.2** Illumination levels shall be permitted to decline to not less than an average of 0.6 ft-candle (6.5 lux) and, at any point, not less than 0.06 ft-candle (0.65 lux) at the end of 1½ hours.

**7.9.2.1.3** The maximum-to-minimum illumination shall not exceed a ratio of 40 to 1.

The *Code* requires a 1 ft-candle (10.8 lux) average and establishes a 0.1 ft-candle (1.1 lux) minimum, with a uniformity ratio maximum of 40 to 1 to prevent excessively bright and dark spots.

**7.9.2.2** New emergency power systems for emergency lighting shall be at least Type 10, Class 1.5, Level 1, in accordance with NFPA 110, *Standard for Emergency and Standby Power Systems*.

A Type 10 emergency power supply system (EPSS) must restore power within 10 seconds of the failure of the primary power source. A Class 1.5 EPSS must be capable of operating at its rated load without being refueled for a minimum of 1½ hours. Level 1 performance is specified based on the technical committee's judgment that failure of the EPSS is critical to human life and safety. For an example where Level 2 performance, for EPSS less critical to human life and safety, is specified in the *Code*, see **7.2.3.12** related to powering mechanical ventilation equipment for smokeproof enclosures. See also NFPA 110, *Standard for Emergency and Standby Power Systems*.

**7.9.2.3\*** The emergency lighting system shall be arranged to provide the required illumination automatically in the event of any interruption of normal lighting due to any of the following:

- (1) Failure of a public utility or other outside electrical power supply
- (2) Opening of a circuit breaker or fuse
- (3) Manual act(s), including accidental opening of a switch controlling normal lighting facilities

**A.7.9.2.3** Where emergency lighting is provided by automatic transfer between normal power service and an emergency generator, it is the intent to prohibit the installation, for any reason, of a single switch that can interrupt both energy sources.

The emergency lighting provisions of **7.9.2.3** are more stringent than those in NFPA 70, *National Electrical Code*. Compliance with the criterion of **7.9.2.3(2)**, related to interruption of normal lighting due to the opening of a circuit breaker or fuse, requires careful design and installation. The requirement can be met by

providing a minimum of two lighting circuits in a room. If the breaker controlling one of the two lighting circuits is opened, there is still illumination in the room, so that there is no interruption of normal lighting and no resulting requirement to switch over to emergency lighting.

The second breaker serving the lighting circuits in the room should be installed on a subpanel separate from the subpanel serving the first breaker. If a common subpanel were used for both lighting circuits, the opening of the main breaker in that subpanel would interrupt normal lighting in the room so as to trigger the need to provide emergency lighting. The common subpanels would introduce the need to monitor those subpanels for the purpose of automatically switching over to emergency lighting — a complication that would be unacceptable to most building operators.

The wiring for the independent lighting subpanels needs to come together somewhere in order to provide them with power, and that typically occurs at the main service entrance/panel. The main breaker can be monitored in the same way that the incoming public power is monitored, so as to automatically provide emergency lighting upon interruption of power.

**7.9.2.4** Emergency generators providing power to emergency lighting systems shall be installed, tested, and maintained in accordance with NFPA 110, *Standard for Emergency and Standby Power Systems*. Stored electrical energy systems, where required in this *Code*, other than battery systems for emergency luminaires in accordance with **7.9.2.5**, shall be installed and tested in accordance with NFPA 111, *Standard on Stored Electrical Energy Emergency and Standby Power Systems*.

The provision of **7.9.2.4** clarifies that battery systems for emergency luminaires are to comply with **7.9.2.5**, which requires listing per ANSI/UL 924, *Standard for Emergency Lighting and Power Equipment*.

**7.9.2.5** Unit equipment and battery systems for emergency luminaires shall be listed to ANSI/UL 924, *Standard for Emergency Lighting and Power Equipment*.

**7.9.2.6** Existing battery-operated emergency lights shall use only reliable types of rechargeable batteries provided with suitable facilities for maintaining them in properly charged condition. Batteries used in such lights or units shall be approved for their intended use and shall comply with NFPA 70, *National Electrical Code*.

**7.9.2.7** The emergency lighting system shall be either continuously in operation or shall be capable of repeated automatic operation without manual intervention.

## 7.9.3 Periodic Testing of Emergency Lighting Equipment.

**7.9.3.1** Required emergency lighting systems shall be tested in accordance with one of the three options offered by **7.9.3.1.1**, **7.9.3.1.2**, or **7.9.3.1.3**.

**7.9.3.1.1** Testing of required emergency lighting systems shall be permitted to be conducted as follows:

- (1) Functional testing shall be conducted monthly, with a minimum of 3 weeks and a maximum of 5 weeks between tests, for not less than 30 seconds, except as otherwise permitted by 7.9.3.1.1(2).
- (2)\* The test interval shall be permitted to be extended beyond 30 days with the approval of the authority having jurisdiction.
- (3) Functional testing shall be conducted annually for a minimum of 1½ hours if the emergency lighting system is battery powered.
- (4) The emergency lighting equipment shall be fully operational for the duration of the tests required by 7.9.3.1.1(1) and (3).
- (5) Written records of visual inspections and tests shall be kept by the owner for inspection by the authority having jurisdiction.

**A.7.9.3.1.1(2)** Technical justification for extending test intervals past 30 days should be based on recorded event history (data) and should include evaluation of the following criteria:

- (1) Number of egress lighting units
- (2) Number of 30-second tests for analysis
- (3) Re-evaluation period (confirm or adjust intervals)
- (4) Number of fixtures found obstructed
- (5) Number of fixtures found misaligned
- (6) Fixtures found to be missing
- (7) Fixtures found damaged
- (8) Battery design
- (9) Type of light source
- (10) Fixture design (manufacturer)
- (11) Number of light fixtures per exit path
- (12) Existence of fire, smoke, and thermal barriers
- (13) Evacuation capability
- (14) Maximum egress time
- (15) Hours of occupancy
- (16) Number of recorded bulb failures
- (17) Number of recorded fixture failures
- (18) Single fixture reliability
- (19) Repairs — mean time to repair
- (20) Lighted egress path probability of success or failure — monthly upper tolerance limit
- (21) Lighted egress path probability of success or failure — quarterly upper tolerance limit (estimated)

**7.9.3.1.2** Testing of required emergency lighting systems shall be permitted to be conducted as follows:

- (1) Self-testing/self-diagnostic battery-operated emergency lighting equipment shall be provided.
- (2) Not less than once every 30 days, self-testing/self-diagnostic battery-operated emergency lighting equipment

shall automatically perform a test with a duration of a minimum of 30 seconds and a diagnostic routine.

- (3) Self-testing/self-diagnostic battery-operated emergency lighting equipment shall indicate failures by a status indicator.
- (4) A visual inspection shall be performed at intervals not exceeding 30 days.
- (5) Functional testing shall be conducted annually for a minimum of 1½ hours.
- (6) Self-testing/self-diagnostic battery-operated emergency lighting equipment shall be fully operational for the duration of the 1½-hour test.
- (7) Written records of visual inspections and tests shall be kept by the owner for inspection by the authority having jurisdiction.

**7.9.3.1.3** Testing of required emergency lighting systems shall be permitted to be conducted as follows:

- (1) Computer-based, self-testing/self-diagnostic battery-operated emergency lighting equipment shall be provided.
- (2) Not less than once every 30 days, emergency lighting equipment shall automatically perform a test with a duration of a minimum of 30 seconds and a diagnostic routine.
- (3) The emergency lighting equipment shall automatically perform annually a test for a minimum of 1½ hours.
- (4) The emergency lighting equipment shall be fully operational for the duration of the tests required by 7.9.3.1.3(2) and (3).
- (5) The computer-based system shall be capable of providing a report of the history of tests and failures at all times.

Periodic testing of emergency lighting equipment is needed to help ensure such equipment will perform as needed upon failure of normal power. The functional test, required to be conducted by 7.9.3.1.1(1), 7.9.3.1.2(2), and 7.9.3.1.3(2), ensures that the bulbs and other equipment work. Additionally, for battery-powered equipment, the 30-second performance criterion for the functional test demonstrates that batteries have more than a residual charge. The 1½-hour performance criterion required yearly for battery-powered equipment ensures sufficient battery life to provide emergency lighting for the 1½ hours required by 7.9.2.1.

The self-testing/self-diagnostic systems permitted by 7.9.3.1.2 and 7.9.3.1.3 use newer technologies and equipment to automate the testing, thereby reducing the manual labor needed to keep the emergency lighting systems in proper operating condition.

Note that 7.9.3.1.1(1) was revised and 7.9.3.1.1(2) was new to the 2009 edition of the Code. In prior editions, the functional test, which must be performed manually (as contrasted with the functional testing that is conducted automatically by the self-testing/self-diagnostic systems addressed in 7.9.3.1.2 and 7.9.3.1.3), was required to be conducted at 30-day intervals. Where that requirement was followed exactly, testing performed

on January 31 would be performed again the following year on January 25 due to the forward creep caused by 31-day months. The former requirement also offered no leniency for scheduling the testing to avoid weekends when the person responsible for conducting the testing might not normally be present. The current language of 7.9.3.1.1(1) offers flexibility without permitting someone to test, for example, on January 31 and again the next day, February 1, and claim compliance with having tested once in each of those months.

The provision of 7.9.3.1.1(2) offers further flexibility by allowing the AHJ to extend the testing frequency. The text of A.7.9.3.1.1(2) provides guidance on the nature of the technical justification needed to qualify for such an extension.

## 7.10 Marking of Means of Egress

In the fatal Westchase Hilton Hotel fire, which occurred in Houston, Texas, in March of 1982, “several people were confused by the exit markings or the similarity of exit doors and adjacent storage room doors. The directional exit signs within the exit foyers at the ends of the hotel corridors indicated that the exit path from this point would be perpendicular to the exit access corridor. Some of the occupants moved toward the locked storage room doors and away from the exits.”<sup>23</sup>

### 7.10.1 General.

**7.10.1.1 Where Required.** Means of egress shall be marked in accordance with Section 7.10 where required in Chapters 11 through 43.

Marking of means of egress is not required unless specifically called for by the applicable occupancy chapter. Subsection \_\_.2.10 of each occupancy chapter (e.g., 12.2.10 for new assembly occupancies) details where exit signs and directional exit signs are required.

### 7.10.1.2 Exits.

**7.10.1.2.1\*** Exits, other than main exterior exit doors that obviously and clearly are identifiable as exits, shall be marked by an approved sign that is readily visible from any direction of exit access.

**A.7.10.1.2.1** Where a main entrance also serves as an exit, it will usually be sufficiently obvious to occupants so that no exit sign is needed.

The character of the occupancy has a practical effect on the need for signs. In any assembly occupancy, hotel, department store, or other building subject to transient occupancy, the need for signs will be greater than in a building subject to permanent or semipermanent occupancy by the same people, such as an apartment house where the residents are presumed to be familiar with exit facilities by reason of regular use thereof. Even in a

Figure A.7.10.1.2.1 Location of Exit Signs.

permanent residence-type building, however, there is a need for signs to identify exit facilities, such as outside stairs that are not subject to regular use during the normal occupancy of the building.

The requirement for the locations of exit signs visible from any direction of exit access is illustrated in Figure A.7.10.1.2.1.

**7.10.1.2.2\*** Horizontal components of the egress path within an exit enclosure shall be marked by approved exit or directional exit signs where the continuation of the egress path is not obvious.

Some exit stair enclosures, particularly in high-rise buildings where the upper portion of the tower presents a smaller footprint than the base of the building, include horizontal components (much like exit passageways) at floors where the stair enclosure that serves the next group of floors immediately below shifts horizontally in position. Although exit and

directional exit signs are not normally needed within an exit stair enclosure that is stacked vertically without offsets because occupants simply move downward from floor to floor, the presence of the horizontal passageway might confound the egress path. Where the continuation of the egress path is not obvious, 7.10.1.2.2 requires additional exit or directional exit signs.

**A.7.10.1.2.2** The direction of travel to the exit discharge within a stair enclosure with horizontal components in excess of the typical landings might need additional signage to be readily visible or obvious. Exit signs should be installed above doors through which the egress path leads. Directional exit signs should be installed where the horizontal egress path changes directions. The stairway marking signs required by 7.2.2.5.4, provided within the stair enclosure at each floor landing, indicate the vertical direction to exit discharge.

**7.10.1.3 Exit Door Tactile Signage.** Tactile signage shall be provided to meet all of the following criteria, unless otherwise provided in 7.10.1.4:

- (1) Tactile signage shall be located at each exit door requiring an exit sign.
- (2) Tactile signage shall read as follows: EXIT.
- (3) Tactile signage shall comply with ICC/ANSI A117.1, *American National Standard for Accessible and Usable Buildings and Facilities*.

**7.10.1.4 Existing Exemption.** The requirements of 7.10.1.3 shall not apply to existing buildings, provided that the occupancy classification does not change.

All exit door assemblies required to have an exit sign are also required to have tactile signage, unless the exit door assembly is in an existing building and the occupancy classification does not change. The required tactile signage allows persons with vision impairment to identify the door assembly as an exit. For the same reasons that the requirements of 7.5.4 on accessible means of egress are not required for existing buildings, tactile signage is not required in existing buildings, unless the occupancy classification changes.

The provision of 7.10.1.3(3), requiring that the tactile signage be in accordance with ICC/ANSI A117.1, *American National Standard for Accessible and Usable Buildings and Facilities*, has the effect of requiring the EXIT element of the sign to be presented both in raised characters and braille. See the last paragraph of the commentary following 7.2.2.5.4.1(P).

#### 7.10.1.5 Exit Access.

**7.10.1.5.1** Access to exits shall be marked by approved, readily visible signs in all cases where the exit or way to reach the exit is not readily apparent to the occupants.

**7.10.1.5.2\*** New sign placement shall be such that no point in an exit access corridor is in excess of the rated viewing distance or 100 ft (30 m), whichever is less, from the nearest sign.

**A.7.10.1.5.2** For externally illuminated signs in accordance with 7.10.6 and internally illuminated signs listed without a marked viewing distance, the rated viewing distance should be considered to be 100 ft (30 m). Where placing signs at their rated viewing distance requires them to be placed above the line of sight, consideration should be given to proportionally increasing the size of the exit legend to compensate for the additional straight-line distance between the viewer and the sign.

The placement distance requirement in 7.10.1.5.2 applies only to new exit sign installations in corridors. Internally illuminated signs are required by 7.10.7.1 to be listed in accordance with ANSI/UL 924, *Standard for Emergency Lighting and Power Equipment*. The testing procedures of ANSI/UL 924 determine a distance rating for the listed sign. Externally illuminated signs are not required to be listed and do not have a distance rating associated with them; however, they are subject to the maximum 100 ft (30 m) placement distance requirement.

The requirement by 7.10.1.5.2 to position internally illuminated signs based on their listed distance rating is another step toward promoting performance-based design in lieu of the traditional prescription-based approach [i.e., use of the maximum 100 ft (30 m) distance]. Listed exit signs are required to be marked with a distance rating only if the rating is other than the 100 ft (30 m) default value.

**7.10.1.6\* Floor Proximity Exit Signs.** Where floor proximity exit signs are required in Chapters 11 through 43, such signs shall comply with 7.10.3, 7.10.4, 7.10.5, and 7.10.6 for externally illuminated signs and 7.10.7 for internally illuminated signs. Such signs shall be located near the floor level in addition to those signs required for doors or corridors. The bottom of the sign shall be not less than 6 in. (150 mm), but not more than 18 in. (455 mm), above the floor. For exit doors, the sign shall be mounted on the door or adjacent to the door, with the nearest edge of the sign within 4 in. (100 mm) of the door frame.

**A.7.10.1.6** See A.7.10.3.

Because locations near the ceiling might be the first to become obstructed by smoke, the provision of 7.10.1.6 makes it possible for the occupancy chapters to specify floor proximity signs to supplement the regular exit signs that are usually placed above the exit door opening or near the ceiling in corridors. Such signs are not intended to replace standard exit signs but are designed as an extra asset to a building occupant seeking egress in a smoke-filled environment. Because the signs are positioned near the floor, they will be among the last signs to become obscured by the descending smoke layer. Exhibit 7.192 shows a floor proximity exit sign at the base of an exit door that is equipped with the traditional exit sign above the door opening.

The provisions of 7.10.1.6 can be used as guidance on the placement and installation of floor proximity signs, even though they might not be required.

Exhibit 7.192

Floor proximity EXIT sign. (Photo courtesy of Jake Pauls)

The only occupancy classification currently mandating floor proximity exit signs is assembly occupancies, where they are required in special amusement buildings in accordance with the provisions of 12.4.8.7.2 and 13.4.8.7.2.

**7.10.1.7\* Floor Proximity Egress Path Marking.** Where floor proximity egress path marking is required in Chapters 11 through 43, an approved floor proximity egress path marking system that is internally illuminated shall be installed within 18 in. (455 mm) of the floor. Floor proximity egress path marking systems shall be listed in accordance with ANSI/UL 1994, *Standard for Luminous Egress Path Marking Systems*. The system shall provide a visible delineation of the path of travel along the designated exit access and shall be essentially continuous, except as interrupted by doorways, hallways, corridors, or other such architectural features. The system shall operate continuously or at any time the building fire alarm system is activated. The activation, duration, and continuity of operation of the system shall be in accordance with 7.9.2. The system shall be maintained in accordance with the product manufacturing listing.

**A.7.10.1.7** See 3.3.146.2 for the definition of the term *internally illuminated*.

Paragraph 7.10.1.7 provides a standard for floor proximity egress path marking for mandatory use by the occupancy chapters or for voluntary use by any party. This type of marking has been mandatory on aircraft for several years. It is not mandatory for any occupancy under the Code. However, it could be used as part

of the directional exit marking required for special amusement buildings by the provisions of 12.4.8.7.3 and 13.4.8.7.3. Such systems are required by 7.10.1.7 to be listed (see 3.2.5 for the definition of the term *listed*).

The provisions of 7.10.1.7 require that floor proximity egress path marking systems be internally illuminated. Photoluminescent egress path markers (like photoluminescent exit signs addressed in 7.10.7.2) are internally illuminated. The photoluminescent material stores incident electromagnetic radiation, typically from ambient light sources, and releases it in the form of visible light. The intensity and duration of the ambient light needed for charging the photoluminescent material varies by product and manufacturer. Thus, 7.10.1.7 requires that the system be maintained in accordance with the product manufacturing listing.

**7.10.1.8\* Visibility.** Every sign required in Section 7.10 shall be located and of such size, distinctive color, and design that it is readily visible and shall provide contrast with decorations, interior finish, or other signs. No decorations, furnishings, or equipment that impairs visibility of a sign shall be permitted. No brightly illuminated sign (for other than exit purposes), display, or object in or near the line of vision of the required exit sign that could detract attention from the exit sign shall be permitted.

In some locations, an otherwise adequate exit sign or directional exit sign might be rendered inconspicuous by a high-intensity illuminated advertising sign in the immediate vicinity. For this reason, such signs are not permitted in the line of vision of any required sign addressed by Section 7.10.

The maximum mounting height for directional exit signs not associated with an egress opening is not specified, and the minimum mounting height for exit signs and directional exit signs is not specified (see 7.10.1.9). Usually they are placed above exit door openings and above head height. There are those who argue, with reason, that smoke builds up more rapidly at higher levels, and signs positioned near the floor would be visible for a much longer time during a fire. However, when several people are moving toward an exit, those in the rear might not be able to see signs located near the floor because of the obstruction created by those ahead of them. Also, in the absence of careful housekeeping, such signs might be damaged or blocked. Thus, 7.10.1.8 treats the subject as a visibility issue and requires that the signs be located to be readily visible and to provide contrast with their surroundings. See also 7.10.1.9 and its related commentary.

**A.7.10.1.8** In stores, for example, an otherwise adequate exit sign could be rendered inconspicuous by a high-intensity illuminated advertising sign located in the immediate vicinity.

Red is the traditional color for exit signs and is required by law in many places. However, at an early stage in the development of the Code, a provision made green the color for exit signs,

following the concept of traffic lights in which green indicates safety and red is the signal to stop. During the period when green signs were specified by the *Code*, many such signs were installed, but the traditional red signs also remained. In 1949, the Fire Marshals Association of North America voted to request that red be restored as the required exit sign color, because it was found that the provision for green involved difficulties in law enactment that were out of proportion to the importance of safety. Accordingly, the 10th edition of the *Code* specified red where not otherwise required by law. The present text avoids any specific requirement for color, based on the assumption that either red or green will be used in most cases and that there are some situations in which a color other than red or green could actually provide better visibility.

As indicated in A.7.10.1.8, the issue of sign color has been the subject of considerable debate. The predecessor to this *Code*, the *Building Exits Code* (see the commentary following 1.1.1) required, from its first edition in 1927 through 1947, that exit signs use white letters on a green field, unless such color was contrary to local law. The text in A.7.10.1.8 describes the development of events since 1949. Currently, color is not specified.

**7.10.1.9 Mounting Location.** The bottom of new egress markings shall be located at a vertical distance of not more than 6 ft 8 in. (2030 mm) above the top edge of the egress opening intended for designation by that marking. Egress markings shall be located at a horizontal distance of not more than the required width of the egress opening, as measured from the edge of the egress opening intended for designation by that marking to the nearest edge of the marking.

Paragraph 7.10.1.9 addresses the mounting location of exit signs associated with an egress opening such as a door opening, an archway, or a portal. Its provisions are meant to keep the sign from being located too high above the egress opening and too far to the side of the egress opening, at which point the sign would be less effective in designating the opening as the egress route.

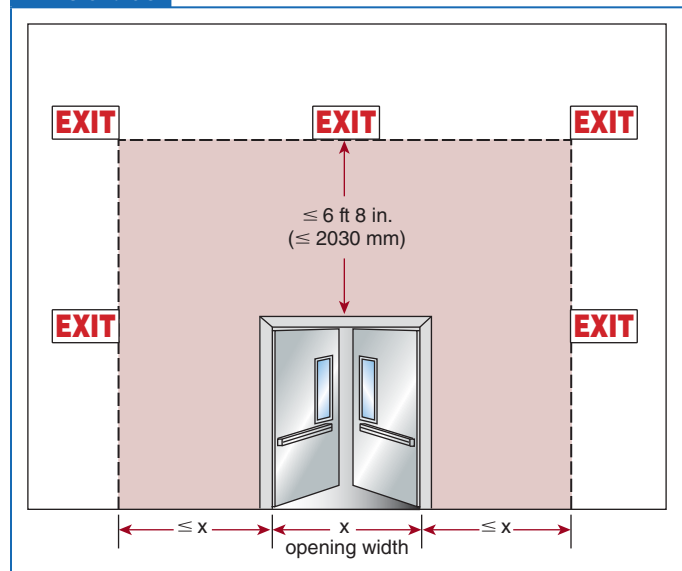

Exhibit 7.193 illustrates the maximum distance at which the nearest sign edge is permitted to be positioned above and to the side of the egress opening, which, in this illustration, is a pair of door leaves. Measurement  $x$ , shown below the door leaves, is the required width of the egress opening.

## 7.10.2 Directional Signs.

**7.10.2.1** A sign complying with 7.10.3, with a directional indicator showing the direction of travel, shall be placed in every location where the direction of travel to reach the nearest exit is not apparent.

The provision of 7.10.2.1 mandates that a directional sign be placed where the direction of travel to reach the nearest exit is not apparent. The directional sign uses an exit sign to which one or two directional indicators are added. For externally

Exhibit 7.193

Maximum permitted distance of sign edge above and to the side of egress opening.

illuminated signs, which are not required to be laboratory listed, the detailed criteria for the directional indicator appear in 7.10.6.2. Internally illuminated signs, which are required to be tested and listed in accordance with ANSI/UL 924, *Standard for Emergency Lighting and Power Equipment*, have their directional indicators evaluated by the performance criteria of the ANSI/UL 924 test procedure; they are exempt from the specification-based criteria of 7.10.6.2.

The requirement of 7.10.2.1 is somewhat performance-based in that it adds another directional exit sign wherever the direction of travel to reach the nearest exit is not apparent. The enforcement of this provision will typically be somewhat subjective, because a judgment call must be made as to whether the direction of travel to reach the nearest exit is apparent. A strict reading and application of the requirement, especially with respect to the word “nearest,” could conceivably lead to the installation of many more signs than are practically needed.

Exhibit 7.194 depicts a warehouse with storage racks and aisles. The racks are of sufficient height and construction to prevent an occupant located within almost any aisle from seeing either of the exit door assemblies from the building. The designer is charged with specifying exit sign and directional sign placement that meets the provisions of Section 7.10. An occupant standing at point X within an aisle has a choice of many possible paths for travel to the two exit door assemblies; there are no dead-end aisles in which to become trapped. The criterion test for exit sign placement is 7.10.2.1, which requires that a directional sign be placed in every location where the direction of travel to reach the “nearest” exit is not apparent. Exit door assembly 1 is the nearest exit, but neither exit door assembly 1 nor exit

Exhibit 7.194

Warehouse exit sign and directional sign placement to be determined.

Exhibit 7.195

Excessive placement of directional signs.

door assembly 2 can be seen from within the aisle or from within any of the three cross-aisles. A strict interpretation of 7.10.2.1, coupled with the requirement of 7.10.1.2.1 that the exit door assemblies themselves be provided with exit signs, could lead to the installation of 20 signs, as shown in Exhibit 7.195. A reasonable person would argue that it is neither unreasonable nor unsafe to reduce the number of signs so as to require the occupant to travel to either of the two nearest cross-aisles in order to see a directional sign that leads to an exit. A check for reasonableness could lead to the placement of eight signs, as shown in Exhibit 7.196.

**7.10.2.2** Directional exit signs shall be provided within horizontal components of the egress path within exit enclosures as required by 7.10.1.2.2.

Some exit stair enclosures, particularly in high-rise buildings where the upper portion of the tower presents a smaller footprint than the base of the building, include horizontal components (much like exit passageways) at floors where the stair enclosure that serves the next group of floors immediately below shifts horizontally in position. Although directional exit signs are not normally needed within an exit stair enclosure that is stacked vertically without offsets because occupants simply move downward from floor to floor, the presence of the horizontal passageway might confound the egress path. Where the continuation of the egress path is not obvious, 7.10.1.2.2 requires additional exit signs or directional exit signs.

Exhibit 7.196

Reasonable placement of directional signs.

### 7.10.3\* Sign Legend.

**A.7.10.3** Where graphics are used, the symbols provided in NFPA 170, *Standard for Fire Safety and Emergency Symbols*, should be used. Such signs need to provide equal visibility and illumination and are to comply with the other requirements of [Section 7.10](#).

**7.10.3.1** Signs required by [7.10.1](#) and [7.10.2](#) shall read as follows in plainly legible letters, or other appropriate wording shall be used:

EXIT

**7.10.3.2\*** Where approved by the authority having jurisdiction, pictograms in compliance with NFPA 170, *Standard for Fire Safety and Emergency Symbols*, shall be permitted.

**A.7.10.3.2** Pictograms are permitted to be used in lieu of, or in addition to, signs with text.

**Paragraph 7.10.3.1** permits other wording in lieu of the word EXIT where the alternative wording is appropriate. In countries where Spanish is the predominant language, one might find the word SALIDA. In some Canadian provinces, where signage appears in both French and English, exit signs have been increased in size to accommodate the words EXIT and SORTIE.

Although [7.10.3.1](#) refers to wording “in plainly legible letters,” it is evident from the language of [7.10.3.2](#) that graphics, or pictograms, in lieu of words are permitted with the approval of the AHJ. Graphics have the advantage of being nonspecific to a written language. **Paragraph 7.10.3.2** specifies that the pictograms comply with NFPA 170, *Standard for Fire Safety and Emergency Symbols*. NFPA 170 provides a symbol for an emergency exit that should be considered the equivalent of the *Life Safety Code’s* exit sign. NFPA 170 also provides two symbols that — when used together within the same rectangular field — designate an emergency exit route. This diptych uses the emergency exit symbol and an arrow symbol and should be considered the equivalent of the *Code’s* directional exit sign. See [Exhibit 7.197](#) and [Exhibit 7.198](#). The colors used in the exhibits are consistent with the requirements of NFPA 170.

**7.10.4\* Power Source.** Where emergency lighting facilities are required by the applicable provisions of [Chapters 11](#) through

**Exhibit 7.197**

NFPA 170 symbol for emergency exit.

**Exhibit 7.198**

NFPA 170 symbols for emergency exit route.

[43](#) for individual occupancies, the signs, other than approved self-luminous signs and listed photoluminescent signs in accordance with [7.10.7.2](#), shall be illuminated by the emergency lighting facilities. The level of illumination of the signs shall be in accordance with [7.10.6.3](#) or [7.10.7](#) for the required emergency lighting duration as specified in [7.9.2.1](#). However, the level of illumination shall be permitted to decline to 60 percent at the end of the emergency lighting duration.

**A.7.10.4** It is not the intent of this paragraph to require emergency lighting but only to have the sign illuminated by emergency lighting if emergency lighting is required and provided.

It is not the intent to require that the entire stroke width and entire stroke height of all letters comprising the word EXIT be visible per the requirements of [7.10.6.3](#) under normal or emergency lighting operation, provided that the sign is visible and legible at a 100 ft (30 m) distance under all room illumination conditions.

The text of [A.7.10.4](#) explains that it is not the intent of [7.10.4](#) to require an emergency power source for the illumination of exit signs. Rather, it is the intent that the required exit signs are provided with emergency power if the occupancy is required to have emergency lighting. For example, there are business occupancies that are small enough to be exempt from the emergency lighting requirement of [38.2.9.1](#) and [39.2.9.1](#). Yet, business occupancies are required to have exit signs in accordance with [Section 7.10](#). Such exit signs are required to be illuminated per [7.10.5.1](#). In a small business occupancy that is exempt from emergency lighting, if a power failure occurs, the exit signs are permitted to go dark. The business occupancy example can be contrasted with an assembly occupancy. Assembly occupancies are required to have emergency lighting and exit signs. The exit signs must be illuminated in accordance with [7.10.5.1](#) when the building’s normal power is available; the illumination must also be maintained in accordance with [7.10.4](#) upon failure of the normal power service.

### 7.10.5 Illumination of Signs.

**7.10.5.1\* General.** Every sign required by [7.10.1.2](#), [7.10.1.5](#), or [7.10.8.1](#), other than where operations or processes require low lighting levels, shall be suitably illuminated by a reliable light

source. Externally and internally illuminated signs shall be legible in both the normal and emergency lighting mode.

**A.7.10.5.1** See A.7.8.1.3(4).

Internally illuminated signs are particularly useful in occupancies where reduction of normal illumination is permitted, such as in movie theaters. However, the intent of 7.10.5.1 is to treat externally illuminated and internally illuminated signs equally, with no preference shown to one or the other. Subsequent subsections then treat each type of sign via a specialized package of requirements, such as 7.10.6 for externally illuminated signs and 7.10.7 for internally illuminated signs. This format is provided because externally illuminated signs are not required to be tested and listed by a laboratory. Due to the lack of testing, it is necessary for the Code to specify detailed criteria for externally illuminated signs, such as the letter height and stroke width addressed in 7.10.6.1.1 and illumination levels as addressed in 7.10.6.3. Because internally illuminated signs must be laboratory tested and listed, the Code can rely on the listing to ensure that necessary criteria are met.

**7.10.5.2\* Continuous Illumination.**

**A.7.10.5.2** It is the intent to prohibit the use of a freely accessible light switch to control the illumination of either an internally or externally illuminated exit sign.

**7.10.5.2.1** Every sign required to be illuminated by 7.10.6.3, 7.10.7, and 7.10.8.1 shall be continuously illuminated as required under the provisions of Section 7.8, unless otherwise provided in 7.10.5.2.2.

**7.10.5.2.2\*** Illumination for signs shall be permitted to flash on and off upon activation of the fire alarm system.

**A.7.10.5.2.2** The flashing repetition rate should be approximately one cycle per second, and the duration of the off-time should not exceed ¼ second per cycle. During on-time, the illumination levels need to be provided in accordance with 7.10.6.3. Flashing signs, when activated with the fire alarm system, might be of assistance.

**7.10.6 Externally Illuminated Signs.**

**7.10.6.1\* Size of Signs.**

**A.7.10.6.1** Experience has shown that the word EXIT, or other appropriate wording, is plainly legible at 100 ft (30 m) if the letters are as large as specified in 7.10.6.1.

**7.10.6.1.1** Externally illuminated signs required by 7.10.1 and 7.10.2, other than approved existing signs, unless otherwise provided in 7.10.6.1.2, shall read EXIT or shall use other appropriate wording in plainly legible letters sized as follows:

- (1) For new signs, the letters shall be not less than 6 in. (150 mm) high, with the principal strokes of letters not less than ¾ in. (19 mm) wide.

- (2) For existing signs, the required wording shall be permitted to be in plainly legible letters not less than 4 in. (100 mm) high.
- (3) The word EXIT shall be in letters of a width not less than 2 in. (51 mm), except the letter I, and the minimum spacing between letters shall be not less than ⅜ in. (9.5 mm).
- (4) Sign legend elements larger than the minimum established in 7.10.6.1.1(1) through (3) shall use letter widths, strokes, and spacing in proportion to their height.

**7.10.6.1.2** The requirements of 7.10.6.1.1 shall not apply to marking required by 7.10.1.3 and 7.10.1.7.

Traditionally, the letters in an exit sign have been required to be 6 in. (150 mm) in height, with the principal strokes not less than ¾ in. (19 mm) wide. In an effort to increase visibility, the Code requires that the letters, other than I, be at least 2 in. (51 mm) wide and have a minimum spacing between letters of ⅜ in. (9.5 mm). These dimensional criteria have been maintained, but they apply only to externally illuminated signs. Internally illuminated signs are exempt from these criteria, because they must be tested and listed in accordance with ANSI/UL 924, *Standard for Emergency Lighting and Power Equipment*. The ANSI/UL 924 test procedures include assessing the readability of a sign's letters.

**7.10.6.2\* Size and Location of Directional Indicator.**

**A.7.10.6.2** Figure A.7.10.6.2 shows examples of acceptable locations of directional indicators with regard to left and right orientation. Directional indicators are permitted to be placed under the horizontal stroke of the letter T, provided that spacing of not less than ⅜ in. (10 mm) is maintained from the horizontal and vertical strokes of the letter T.

EXIT >  
<EXIT  
<EXIT >

*Figure A.7.10.6.2 Directional Indicators.*

**7.10.6.2.1** Directional indicators, unless otherwise provided in 7.10.6.2.2, shall comply with all of the following:

- (1) The directional indicator shall be located outside of the EXIT legend, not less than ⅜ in. (9.5 mm) from any letter.
- (2) The directional indicator shall be of a chevron type, as shown in Figure 7.10.6.2.1.
- (3) The directional indicator shall be identifiable as a directional indicator at a distance of 40 ft (12 m).
- (4) A directional indicator larger than the minimum established for compliance with 7.10.6.2.1(3) shall be proportionately increased in height, width, and stroke.
- (5) The directional indicator shall be located at the end of the sign for the direction indicated.

Figure 7.10.6.2.1 Chevron-Type Indicator.

**7.10.6.2.2** The requirements of 7.10.6.2.1 shall not apply to approved existing signs.

To improve the effectiveness of directional indicators on directional exit signs, the requirements have been changed over the past several editions of the *Code*. The directional indicator cannot be positioned between the letters in the word EXIT. The directional indicator, which formerly was an arrow, must be a chevron. Research showed that a chevron indicator was more effective than an arrow. Performance criteria are specified to ensure that the chevron is of adequate size, contrast, and illumination. A specific size is not required, because size depends on factors such as color, contrast, and illumination. However, the directional indicator must be identifiable as a directional indicator at a minimum distance of 40 ft (12 m), which is another performance-based requirement.

**7.10.6.3\* Level of Illumination.** Externally illuminated signs shall be illuminated by not less than 5 ft-candles (54 lux) at the illuminated surface and shall have a contrast ratio of not less than 0.5.

**A.7.10.6.3** Colors providing a good contrast are red or green letters on matte white background. Glossy background and glossy letter colors should be avoided.

The average luminance of the letters and background is measured in footlamberts or candela per square meter. The contrast ratio is computed from these measurements by the following formula:

$$\text{Contrast} = \frac{L_g - L_e}{L_g} \quad [\text{A.7.10.6.3}]$$

Where  $L_g$  is the greater luminance and  $L_e$  is the lesser luminance, either the variable  $L_g$  or  $L_e$  is permitted to represent the letters, and the remaining variable will represent the background. The average luminance of the letters and background can be computed by measuring the luminance at the positions indicated in Figure A.7.10.6.3 by numbered circles.

### 7.10.7 Internally Illuminated Signs.

**7.10.7.1 Listing.** Internally illuminated signs shall be listed in accordance with ANSI/UL 924, *Standard for Emergency Lighting*

Figure A.7.10.6.3 Measurement of Exit Sign Luminance.

and Power Equipment, unless they meet one of the following criteria:

- (1) They are approved existing signs.
- (2) They are existing signs having the required wording in legible letters not less than 4 in. (100 mm) high.
- (3) They are signs that are in accordance with 7.10.1.3 and 7.10.1.6.

Internally illuminated signs must be laboratory tested and listed in accordance with ANSI/UL 924, *Standard for Emergency Lighting and Power Equipment*. Reliance is placed on the laboratory having conducted a comprehensive examination. By relying on the laboratory listing, the *Code* does not need to address the detailed criteria that it requires of externally illuminated signs, which are not required to be listed.

**7.10.7.2\* Photoluminescent Signs.** The face of a photoluminescent sign shall be continually illuminated while the building is occupied. The illumination levels on the face of the photoluminescent sign shall be in accordance with its listing. The charging illumination shall be a reliable light source, as determined by the authority having jurisdiction. The charging light source, shall be of a type specified in the product markings.

**A.7.10.7.2** Photoluminescent signs need a specific minimum level of light on the face of the sign to ensure that the sign is charged for emergency operation and legibility in both the normal and emergency modes. Additionally, the type of light source (e.g., incandescent, fluorescent, halogen, metal halide) is important. Each light source produces different types of visible and invisible light (e.g., UV) that might affect the ability of some photoluminescent signs to charge and might also affect the amount of light output available during emergency mode. This type of sign would not be suitable where the illumination levels are permitted to decline. The charging light source should not be connected to automatic timers, because continuous illumination of the sign is needed; otherwise, the sign illumination would not be available, because it would be discharged.

A photoluminescent sign absorbs light from an activation light source in order to emit light (i.e., luminesce). The sign continues

to emit light for a time after the activation light source has been removed. **Exhibit 7.199** shows a normally lighted room with a photoluminescent EXIT sign with green background and two directional EXIT signs — one with black background and one with red background — complete with the chevron-shaped directional indicator addressed in **7.10.6.2.1**. **Exhibit 7.200** shows the same three photoluminescent EXIT signs as shown in **Exhibit 7.199**, but with the room darkened to take advantage of the internal illumination provided by the glow of the photoluminescent material in the sign.

**Exhibit 7.199**

Photoluminescent EXIT signs with normal lighting. (Photo courtesy of American PERMALIGHT®, Inc.)

**Exhibit 7.200**

Photoluminescent EXIT signs in darkened space. (Photo courtesy of American PERMALIGHT®, Inc.)

Although the photoluminescent (i.e., internally illuminated) signs shown in **Exhibit 7.199** are not photographed with a measuring stick to indicate size, the EXIT legend is smaller than that required for externally illuminated signs by **7.10.6.1.1**. The internally illuminated signs shown have been tested and listed to ANSI/UL 924, *Standard for Emergency Lighting and Power Equipment*, for a rated viewing distance of 50 ft (15 m). The rated viewing distance is prominently displayed at the top of the sign above the word EXIT. If no viewing distance is specified on the sign, the default distance of 100 ft (30 m), as addressed in **7.10.1.5.2**, applies.

The requirements of **7.10.7.2** for photoluminescent signs were new to the 2000 edition of the *Code*. Note that these requirements are contained as a subset of the internally illuminated sign requirements of **7.10.7**. A photoluminescent sign is an internally illuminated sign. Photoluminescent exit signs are permitted, provided that they are listed in accordance with ANSI/UL 924 and meet the criteria of **7.10.7.2**. The criteria of **7.10.7.2** are meant to highlight some of the special considerations needed to use photoluminescent exit signs effectively for life safety.

## 7.10.8 Special Signs.

### 7.10.8.1 Sign Illumination.

**7.10.8.1.1\*** Where required by other provisions of this *Code*, special signs shall be illuminated in accordance with **7.10.5**, **7.10.6.3**, and **7.10.7**.

**A.7.10.8.1.1** Special signs require sufficient illumination in order for them to be readable at close proximity. They are not expected to be of a size or illumination level necessary to be readable from a distance, as is the case for an exit sign.

**7.10.8.1.2** Where emergency lighting facilities are required by the applicable provisions of **Chapters 11** through **43**, the required illumination of special signs shall additionally be provided under emergency lighting conditions.

**7.10.8.2 Characters.** Special signs, where required by other provisions of this *Code*, shall comply with the visual character requirements of ICC/ANSI A117.1, *American National Standard for Accessible and Usable Buildings and Facilities*.

### 7.10.8.3\* No Exit.

**A.7.10.8.3** The likelihood of occupants mistaking passageways or stairways that lead to dead-end spaces for exit doors and becoming trapped governs the need for exit signs. Thus, such areas should be marked with a sign that reads as follows:

NO EXIT

Supplementary identification indicating the character of the area, such as TO BASEMENT, STOREROOM, LINEN CLOSET, or the like, is permitted to be provided.

**7.10.8.3.1** Any door, passage, or stairway that is neither an exit nor a way of exit access and that is located or arranged so that it is likely to be mistaken for an exit shall be identified by a sign that reads as follows:

**NO**  
EXIT

**7.10.8.3.2** The NO EXIT sign shall have the word NO in letters 2 in. (51 mm) high, with a stroke width of  $\frac{3}{8}$  in. (9.5 mm), and the word EXIT in letters 1 in. (25 mm) high, with the word EXIT below the word NO, unless such sign is an approved existing sign.

**7.10.8.4 Elevator Signs.** Elevators that are a part of a means of egress (*see 7.2.13.1*) shall have both of the following signs with a minimum letter height of  $\frac{3}{8}$  in. (16 mm) posted in every elevator lobby:

(1)\* Signs that indicate that the elevator can be used for egress, including any restrictions on use

**A.7.10.8.4(1)** These signs are to be used in place of signs that indicate that elevators are not to be used during fires. Examples of these signs include the following:

In the Event of Fire, This Elevator Will Be Used  
by the Fire Department for Evacuation of People.

PROTECTED ELEVATOR—  
USABLE IN EMERGENCIES

(2)\* Signs that indicate the operational status of elevators

**A.7.10.8.4(2)** The wording of these signs should reflect human behavior in fires and the control specifics of the elevator system. **Subparagraph 7.10.8.4** addresses signs, but provisions for notification of the vision impaired need to be considered. For information about human behavior with respect to elevator evacuation, see Groner and Levin, “Human Factor Considerations in the Potential for Using Elevators in Building Emergency Evacuation Plans”; Levin and Groner, “Human Behavior Aspects of Staging Areas for Fire Safety in GSA Buildings”; and Levin and Groner, “Human Factor Considerations for the Potential Use of Elevators for Fire Evacuation of FAA Air Traffic Control Towers.” Some examples of messages on signs that could be displayed are shown in **Table A.7.10.8.4(2)**.

**Table A.7.10.8.4(2) Elevator Status Messages**

Elevator Status	Message
Normal use	Elevator in Service
Elevators recalled and waiting for fire service	Please Wait for Fire Department or Use Stairs
Elevator out of service	Elevator Out of Service

The requirements in **7.10.8.4** for elevator signs apply only where the elevator is part of the means of egress. The only current application is for elevators used as the second means of egress from a tower and such tower is not permitted to serve the general public. See **7.2.13.1** and **7.2.13.12**.

**7.10.8.5\* Evacuation Diagram.** Where a posted floor evacuation diagram is required in **Chapters 11** through **43**, floor evacuation diagrams reflecting the actual floor arrangement and exit locations shall be posted and oriented in a location and manner acceptable to the authority having jurisdiction.

**A.7.10.8.5** Egress paths with multiple turns can often be confusing with respect to which exit route will lead to the closest exit door. Floor evacuation diagrams can eliminate the guesswork by giving the occupant a point of reference by the YOU ARE HERE symbol. The entire floor plan should be shown with the primary and secondary exit routes, exit stairs, and elevators clearly identified. For further information, see ASTM E 2238, *Standard Guide for Evacuation Route Diagrams*.

The provision of **7.10.8.5** is formatted such that it applies only where a posted floor evacuation diagram is required by another provision of the *Code*. A floor diagram, reflecting the actual floor arrangement and exit locations, is required for hotels and dormitories by **28.7.4.1** and **29.7.4.1**. It is important that the floor evacuation diagram be oriented so that, if an exit is shown at the right of the diagram, the exit is actually located to the right of the person facing the sign. In a hotel with guest rooms located at both sides of the corridor, the floor diagram for the rooms at one side of the corridor will need to be the mirror image of the floor diagram for the rooms at the other side of the corridor.

## 7.10.9 Testing and Maintenance.

**7.10.9.1 Inspection.** Exit signs shall be visually inspected for operation of the illumination sources at intervals not to exceed 30 days or shall be periodically monitored in accordance with **7.9.3.1.3**.

**7.10.9.2 Testing.** Exit signs connected to, or provided with, a battery-operated emergency illumination source, where required in **7.10.4**, shall be tested and maintained in accordance with **7.9.3**.

## 7.11 Special Provisions for Occupancies with High Hazard Contents

See **Section 6.2**.

The wording associated with the classification of high hazard contents in **6.2.2.4** states that “high hazard contents shall be classified as those that are likely to burn with extreme rapidity or from which explosions are likely.”

**7.11.1\*** Where the contents are classified as high hazard, exits shall be provided and arranged to allow all occupants to escape

from the building or structure, or from the hazardous area thereof, to the outside or to a place of safety with a travel distance of not more than 75 ft (23 m), measured as required in 7.6.1, unless otherwise provided in 7.11.2.

**A.7.11.1** Seventy-five feet (23 m) can be traversed in approximately 10 seconds to 15 seconds, even when allowing for a momentary delay to decide which way to go, during which it can be assumed that the average individual can hold his or her breath.

**Subsection 7.11.1** does not limit occupants to a 75 ft (23 m) travel distance but requires escape from the high hazard contents area itself with not more than 75 ft (23 m) of travel. The place of safety outside the high hazard area is permitted to be within the building's exit access; additional travel might be necessary to reach an exit.

**7.11.2** The requirement of 7.11.1 shall not apply to storage occupancies as otherwise provided in Chapter 42.

**7.11.3** Egress capacity for high hazard contents areas shall be based on 0.7 in./person (18 mm/person) for stairs or 0.4 in./person (10 mm/person) for level components and ramps in accordance with 7.3.3.1.

**7.11.4** Not less than two means of egress shall be provided from each building or hazardous area thereof, unless all of the following criteria are met:

- (1) Rooms or spaces do not exceed 200 ft<sup>2</sup> (18.6 m<sup>2</sup>).
- (2) Rooms or spaces have an occupant load not exceeding three persons.
- (3) Rooms or spaces have a travel distance to the room door not exceeding 25 ft (7620 mm).

**Subsection 7.11.4** recognizes that it is not always necessary or feasible to provide two ways out of very small high hazard contents spaces. Provided that all three conditional features — limited room area, limited occupant load, and limited travel distance to room door opening — can be met, a single means of egress is permitted.

**7.11.5** Means of egress, for rooms or spaces other than those that meet the criteria of 7.11.4(1) through (3), shall be arranged so that there are no dead ends in corridors.

**7.11.6** Doors serving high hazard contents areas with occupant loads in excess of five shall be permitted to be provided with a latch or lock only if the latch or lock is panic hardware or fire exit hardware complying with 7.2.1.7.

It is not the intent of the Code to apply the provisions of Section 7.11 to the hazardous contents areas addressed by subsection \_\_.3.2 of each occupancy chapter. Those hazardous contents areas are generally rooms or spaces with contents that make them somewhat more hazardous than the rooms or spaces normally associated with a given occupancy. For example, soiled linen storage rooms in a health care occupancy create contents

that are more hazardous than those within a patient room, but they don't create a hazard that warrants protection as high hazard contents by Section 7.11. The decision as to when an area is sufficiently hazardous to warrant protection as high hazard contents by the requirements of Section 7.11 is left to the authority having jurisdiction via use of the classification criteria in 6.2.2.4.

## 7.12 Mechanical Equipment Rooms, Boiler Rooms, and Furnace Rooms

**Section 7.12** applies to mechanical equipment rooms, boiler rooms, and furnace rooms in all buildings, regardless of occupancy. The number of exits and common path of travel limitations in these spaces are addressed independently of the occupancy in which they are located. The presence of these rooms does not result in a facility being designated a multiple occupancy.

**7.12.1** Mechanical equipment rooms, boiler rooms, furnace rooms, and similar spaces shall be arranged to limit common path of travel to a distance not exceeding 50 ft (15 m), unless otherwise permitted by the following:

- (1) A common path of travel not exceeding 100 ft (30 m) shall be permitted in the following locations:
  - (a) In buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7
  - (b) In mechanical equipment rooms with no fuel-fired equipment
  - (c) In existing buildings
- (2) In an existing building, a common path of travel not exceeding 150 ft (46 m) shall be permitted, provided that all of the following criteria are met:
  - (a) The building is protected throughout by an approved, supervised automatic sprinkler system installed in accordance with Section 9.7.
  - (b) No fuel-fired equipment is within the space.
  - (c) The egress path is readily identifiable.
- (3) The requirement of 7.12.1 shall not apply to rooms or spaces in existing health care occupancies complying with the arrangement of means of egress provisions of 19.2.5 and the travel distance limits of 19.2.6.

**7.12.2** Stories used exclusively for mechanical equipment, furnaces, or boilers shall be permitted to have a single means of egress where the travel distance to an exit on that story is not in excess of the common path of travel limitations of 7.12.1.

**Paragraph 7.12.2** is especially useful in equipment penthouses and for basement furnace and boiler rooms. As long as the common path of travel specified by 7.12.1 is not exceeded, a story used exclusively for mechanical equipment, boilers, or furnaces is permitted to be served by a single exit.

## 7.13 Normally Unoccupied Building Service Equipment Support Areas

The provisions of [Section 7.13](#) were new to the 2012 edition of the *Code*. They have the effect of significantly reducing the means of egress features required for normally unoccupied building service equipment support areas. See [3.3.21.6](#) for a definition of *normally unoccupied building service equipment support area*. The advisory annex text that accompanies the definition is repeated below, as it is important not to permit the leniencies offered by [Section 7.13](#) to be used in spaces that should not be classified as normally unoccupied building service equipment support areas.

**A.3.3.21.6 Normally Unoccupied Building Service Equipment Support Area.** Normally unoccupied building service support areas are often found in attics, crawl spaces, chases, and interstitial areas where the space is vacant or intended exclusively for routing ductwork, cables, conduits, piping, and similar services and is rarely accessed. In such spaces, it is often difficult or impossible to fully comply with the egress requirements of [Chapter 7](#). Where portions of such spaces are routinely visited for storage, maintenance, testing, or inspection, that portion is excluded from this definition, but the remainder of the space might be considered a normally unoccupied building service equipment support area. Storage and fuel-fired equipment would not be expected to be permitted in these locations. Roofs are not considered to be normally unoccupied building service equipment support areas.

The two themes that run through [Section 7.13](#) are that the subject egress feature that is normally required by [Chapter 7](#) is exempted in the normally unoccupied building service equipment support area if:

1. The normally unoccupied building service equipment support area is not larger than 45,000 ft<sup>2</sup> (4180 m<sup>2</sup>) in a building that is not sprinklered throughout, without the presence or absence of sprinklers in the normally unoccupied building service equipment support area affecting the determination of whether the building is sprinklered throughout
2. The normally unoccupied building service equipment support area is not larger than 90,000 ft<sup>2</sup> (8370 m<sup>2</sup>) in a building that is sprinklered throughout, without the presence or absence of sprinklers in the normally unoccupied building service equipment support area affecting the determination of whether the building is sprinklered throughout

### 7.13.1\* Hazard of Contents.

**A.7.13.1** 29 CFR 1910.146 of the OSHA regulations describes the aspects of normally unoccupied areas. For example, hazardous atmosphere criteria are presented, and asphyxiation risk due

to an entrance becoming engulfed are addressed. The areas described by 29 CFR 1910.146, “Permitted Required Confined Spaces,” would be considered hazardous if located within a building or structure regulated by NFPA 101.

**7.13.1.1** Unless prohibited by [Chapters 11](#) through [43](#), the provisions of [Section 7.13](#) shall apply, in lieu of the provisions of [Sections 7.1](#) through [7.12](#), to normally unoccupied building service equipment support areas where such areas do not contain high hazard contents or operations.

The provisions of [Section 7.13](#) are permitted to be used, unless otherwise prohibited by [Chapters 11](#) through [43](#). The occupancies prohibiting the use of [Section 7.13](#) are hotels, dormitories, and apartment buildings. See [28.2.11.3](#), [29.2.11.3](#), [30.2.11.3](#), and [31.2.11.3](#).

**7.13.1.2** Building service equipment support areas shall not contain fuel-fired equipment or be used for the storage of combustibles.

### 7.13.2 Egress Doors.

**7.13.2.1\*** Egress from normally unoccupied building service equipment support areas shall be provided by doors complying with [7.2.1](#) where the normally unoccupied building service equipment support area exceeds 45,000 ft<sup>2</sup> (4180 m<sup>2</sup>) in buildings not protected throughout by an approved, supervised automatic sprinkler system in accordance with [9.7.1.1\(1\)](#).

**A.7.13.2.1** Egress from normally unoccupied building service equipment support areas not exceeding 45,000 ft<sup>2</sup> (4180 m<sup>2</sup>) is permitted to be by access panels or other hardware not complying with the door requirements of [7.2.1](#).

**7.13.2.2** Egress from normally unoccupied building service equipment support areas shall be provided by doors complying with [7.2.1](#) where the normally unoccupied building service equipment support area exceeds 90,000 ft<sup>2</sup> (8370 m<sup>2</sup>) in buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with [9.7.1.1\(1\)](#).

The provisions of [7.13.2](#) are worded so as to require that egress be via doors only if the normally unoccupied building service equipment support area is very large. The provisions have the effect of exempting doors from spaces that are smaller than the area thresholds specified. The text of [A.7.13.2.1](#) explains that egress can be served by access panels where doors are not required.

**7.13.2.3** The absence of sprinklers in the normally unoccupied building service equipment support area, as permitted by an exemption of NFPA 13, *Standard for the Installation of Sprinkler Systems*, shall not cause a building to be classified as nonsprinklered for purposes of applying the provisions of [7.13.2.2](#).

### 7.13.3 Means of Egress Path.

**7.13.3.1** A designated means of egress path shall be provided within the normally unoccupied building service equipment

support area where the normally unoccupied area exceeds 45,000 ft<sup>2</sup> (4180 m<sup>2</sup>) in buildings not protected throughout by an approved, supervised automatic sprinkler system in accordance with 9.7.1.1(1).

**7.13.3.2** A designated means of egress path shall be provided within the normally unoccupied building service equipment support area where the normally unoccupied area exceeds 90,000 ft<sup>2</sup> (8370 m<sup>2</sup>) in buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with 9.7.1.1(1).

**7.13.3.3** The absence of sprinklers in the normally unoccupied building service equipment support area, as permitted by an exemption of NFPA 13, *Standard for the Installation of Sprinkler Systems*, shall not cause a building to be classified as nonsprinklered for purposes of applying the provisions of 7.13.3.2.

**7.13.3.4** Where a means of egress path is required, the path shall be a minimum of 28 in. (710 mm) clear width.

**7.13.3.5** Where a means of egress path is required, minimum headroom shall be 6 ft 8 in. (2030 mm) along the entire designated means of egress path.

**7.13.3.6** Exit signage shall not be required along the means of egress path within normally unoccupied building service equipment support areas.

**7.13.3.7** Where two means of egress are required, the means of egress path shall connect the two required means of egress.

**7.13.3.8** The designated means of egress path shall be within 25 ft (7.6 m) of any portion of the space where the only available access requires crossing over or under obstructions, unless the space is completely inaccessible.

The provisions of 7.13.3 are worded so as to require a designated means of egress path only if the normally unoccupied building service equipment support area is very large. The provisions have the effect of exempting requirements related to all of the following from spaces that are smaller than the area thresholds specified:

1. Minimum width
2. Minimum headroom height
3. Exit and directional exit signage
4. Prohibition on travel over and under obstructions

### 7.13.4 Illumination.

**7.13.4.1** The minimum illumination of means of egress along the required means of egress path shall be 0.2 ft-candle (2.2 lux), except as otherwise provided in 7.13.4.2.

**7.13.4.2** Illumination of means of egress shall not be required in normally unoccupied building service equipment support areas where illumination of means of egress is not required by the applicable occupancy chapter for the remainder of the building.

The provisions of 7.13.4 permit the required minimum illumination levels to be just one-fifth of those required by Section 7.8.

### 7.13.5 Number of Means of Egress.

**7.13.5.1** Two remotely located means of egress shall be provided within the normally unoccupied building service equipment support area where the normally unoccupied area exceeds 45,000 ft<sup>2</sup> (4180 m<sup>2</sup>) in buildings not protected throughout by an approved, supervised automatic sprinkler system in accordance with 9.7.1.1(1).

**7.13.5.2** Two remotely located means of egress shall be provided within the normally unoccupied building service equipment support area where the normally unoccupied area exceeds 90,000 ft<sup>2</sup> (8370 m<sup>2</sup>) in buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with 9.7.1.1(1).

**7.13.5.3** The absence of sprinklers in the normally unoccupied building service equipment support area, as permitted by an exemption of NFPA 13, *Standard for the Installation of Sprinkler Systems*, shall not cause a building to be classified as nonsprinklered for purposes of applying the provisions of 7.13.5.2.

The provisions of 7.13.5 are worded so as to require two means of egress only if the normally unoccupied building service equipment support area is very large. The provisions have the effect of exempting two means of egress from spaces that are smaller than the area thresholds specified.

---

## 7.14 Occupant Evacuation Elevators

Section 7.14 provides requirements on the design, installation, and use of occupant evacuation elevators where elevators are used for occupant-controlled evacuation prior to Phase I Emergency Recall Operations mandated by the Firefighters' Emergency Operations provisions of ASME A17.1/CSA B44, *Safety Code for Elevators and Escalators*. Use of the provisions of Section 7.14 is not mandated by any requirement of the Code. Instead, if elevators are to be used for occupant evacuation, such elevators are required to comply with the provisions of Section 7.14 so that such use does not endanger the building occupants. A building developer might use Section 7.14 in the construction documents for a new building in which the elevators are to be used for occupant-controlled evacuation. An owner of an existing building might reference Section 7.14 as part of the specifications for the retrofitting of an elevator in the building for occupant-controlled evacuation. A design professional might consult Section 7.14 for guidance in providing services, even where Section 7.14 is not specifically adopted or referenced.

The content of Section 7.14 had its genesis following the September 11, 2001, attacks on the World Trade Center towers

when Richard Bukowski [then of the National Institute of Standards and Technology (NIST)] requested that the standards-development organizations with interests in elevators, fire and life safety codes, and fire fighter operations work together to develop a framework under which elevators could be used for occupant evacuation and fire-fighting operations. The request was consistent with Recommendation 20 of the NIST Final Report on the Collapse of the World Trade Center Towers, which states:

**Recommendation 20:** NIST recommends that the full range of current and next generation evacuation technologies should be evaluated for future use, including protected/hardened elevators, . . . which may allow all occupants an equal opportunity for evacuation and facilitate emergency response access.<sup>24</sup>

In response to the NIST request, the American Society of Mechanical Engineers (ASME), which publishes ASME A17.1/CSA B44, sponsored the ASME Workshop on Use of Elevators in Fires and Other Emergencies in Atlanta, Georgia, in March 2004. Cosponsors of the workshop included NIST, NFPA, the International Code Council (ICC), the US Access Board, the International Association of Fire Fighters (IAFF), and Elevator World.

Recommendations developed during the ASME workshop were assigned to two ASME task groups for study. The task groups, one on the use of elevators for occupant egress, and the other on the use of elevators by fire fighters, began the work of developing hazard analyses on the respective subjects in October 2004. In December 2010, ASME and the majority of the aforementioned cosponsors held a follow-up workshop in Orlando, Florida. The progress made during six years of meetings was reported.

**Section 7.14** was developed by the NFPA Technical Committee on Means of Egress as Annex B for the 2009 edition of the *Code*. Members of the technical committee have actively participated in the ASME task groups, particularly on the task group related to the use of elevators for occupant egress, so as to be aware of the issues studied and the progress made to date. **Annex B** and **Section 7.14** were written to utilize elevator technology, strengthen building construction elements in the area of the elevators, and enhance information dissemination for building occupants.

### 7.14.1 General.

**7.14.1.1\*** Where passenger elevators for general public use are permitted to be used for occupant evacuation prior to Phase I Emergency Recall Operation mandated by the firefighters' emergency operation provisions of ASME A17.1/CSA B44, *Safety Code for Elevators and Escalators*, the elevator system shall also comply with this section, except as otherwise permitted by **7.14.1.2**.

**A.7.14.1.1** The Phase I emergency recall operation mandated by the fire fighters' emergency operation provisions of ASME

A17.1/CSA B 44, *Safety Code for Elevators and Escalators*, recalls elevators upon detection of smoke by smoke detectors installed in the following locations:

- (1) At each floor served by the elevator in the lobby (landing) adjacent to the hoistway doors
- (2) In the associated elevator machine/control room or machinery/control space
- (3) In the elevator hoistway where sprinklers are located in the hoistway

Where smoke from a fire remote from the elevator lobby (landing), elevator machine/control room or machinery/control space, and elevator hoistway can be kept from reaching the elevator lobby (landing), elevator machine/control room or machinery/control space, and elevator hoistway, the associated elevators can continue to operate in a fire emergency. The provisions of **Section 7.14** address the features that need to be provided to make such elevator operation safe for evacuation.

The commentary for **Section 7.14** is relatively brief, as extensive explanatory material is provided by the annex text. The annex text provides clarification and explanation of intent. For example, **A.7.14.1.1** provides information from which the user learns that the smoke detectors at the elevator lobby/landing, elevator machine room, and elevator hoistway are recall elevators as detailed in ASME A17.1/CSA B44, *Safety Code for Elevators and Escalators*. The provisions of **Section 7.14** are intended to help keep smoke from reaching the smoke detectors that recall the elevators and help ensure that it is safe for those elevators to continue to run during a fire emergency. Smoke that reaches other smoke detectors on the floor should not affect the continued operation of the occupant evacuation elevators.

**7.14.1.2** The provisions of **Section 7.14** shall not apply where the limited or supervised use of elevators for evacuation is part of a formal or informal evacuation strategy, including the relocation or evacuation of patients in health care occupancies and the relocation or evacuation of occupants with disabilities in other occupancies.

The provision of **7.14.1.2** provides important information relative to the intended scope of **Section 7.14**. It is not the intent that a health care occupancy, such as the hospital described in the paragraph that follows, be required to comply with the provisions of **Section 7.14** in order to utilize elevators as part of the emergency plan to evacuate or relocate patients under fire or similar emergency.

**Exhibit 7.201** depicts a patient sleeping floor on the fifth story of an existing five-story hospital. The partitions delineating the sleeping rooms are not shown for purposes of simplifying the exhibit. The smoke barrier divides the floor into two smoke compartments, A and B. Similar smoke barriers are provided on the other four stories at the same relative location as on the fifth story, so that the smoke barriers are vertically aligned throughout the building height, creating two smoke compartments per

Exhibit 7.201

Elevator use for patient evacuation or relocation not subject to the requirements of Section 7.14.

floor, A and B. The written emergency plan provides for patients to be moved by the elevator located in the smoke compartment not involved in the fire. For example, if the fire is in Compartment A of the fifth story, the elevators are not used in Compartment A of any of the stories. The elevator in Compartment B is used to evacuate or relocate patients, as it is on the safe side of the smoke barrier. The emergency plan employed is exempted from compliance with the requirements of Section 7.14.

**7.14.1.3\*** The occupant evacuation elevators shall be in accordance with the occupant evacuation operation (OEO) requirements of ASME A17.1/CSA B44, *Safety Code for Elevators and Escalators*, and the building emergency action plan required by 7.14.3.1.

**A.7.14.1.3** The occupant evacuation operation requirements of ASME A17.1/CSA B44, *Safety Code for Elevators and Escalators*, address the elevator-related features for occupant evacuation elevators — features for which an elevator code has jurisdiction. The requirements were written assuming that necessary and complementary provisions that are not within the purview of an elevator code would be addressed in building, life safety, and fire codes. ASME A17.1/CSA B44 Annex T, titled “Building Features for Elevator Occupant Evacuation Operation (OEO),” lists the building construction features assumed to be present for coordinated use with its provisions for OEO.

The provision of 7.14.1.3 is new to the 2015 edition of the Code. It references the use of the occupant evacuation operation (OEO) requirements of ASME A17.1/CSA B44, *Safety Code for Elevators*

and Escalators. The OEO provisions are new to the 2013 edition of ASME A17.1/CSA B44 and are not part of the 2007 edition referenced in 2.3.4. The OEO provisions utilize new technology, the need for which was identified by the ASME task groups mentioned in the commentary following the Section 7.14 title. The new technology is essential to the proper design and function of the occupant evacuation elevator system addressed by Section 7.14.

The advisory text of A.7.14.1.3 explains the code jurisdictional process under which ASME A17.1/CSA B44 addresses the OEO provisions appropriate for an elevator code, and the codes of other organizations — such as NFPA 101 — address the building construction features needed to support OEO.

**7.14.1.4** Occupant evacuation elevators in accordance with Section 7.14 shall not be permitted to satisfy requirements of this Code applicable to the following:

- (1) Number of means of egress
- (2) Capacity of means of egress
- (3) Arrangement of means of egress

The provision of 7.14.1.4 specifically directs that occupant evacuation elevators in accordance with Section 7.14 are not permitted to satisfy any of the means of egress requirements of the Code related to number, capacity, or arrangement. For example, a floor that is provided with two enclosed exit stairs and one occupant evacuation elevator is credited with having two exits, not three. Where each of the two exit stairs has capacity for 150 persons, the floor’s total egress capacity is 300 persons, as the elevator is not credited with providing any egress capacity. Where one exit stair is at one end of the floor, the second exit stair is at the other end of the floor, and the occupant evacuation elevator is located at the midpoint of the length of the floor, occupants in the vicinity of the elevator must be able to reach one of the exit stairs within the allowable travel distance, as travel distance measurement ends at an exit, and the elevator is not an exit.

The effect of the provision of 7.14.1.4 is that there is no Code-driven incentive to provide occupant evacuation elevators. It is expected that, as Section 7.14 matures over future editions, occupant evacuation elevators that satisfy some of the means of egress requirements will be mandated for new building construction. The technology needed to make an elevator that is an equivalent to an exit stair is in an infant stage. Current interest and development activity suggest that this stage will advance quickly.

**7.14.2 Reserved.**

**7.14.3 Information Features.**

**7.14.3.1\*** An emergency action plan approved by the authority having jurisdiction shall be implemented, specifically including the procedures for occupant evacuation using the exit stairs and the occupant evacuation elevators.

A typical emergency action plan needs to include emergency evacuation or relocation procedures and instructions, specific to the building, in an easy to comprehend format. The emergency action plan required by 7.14.3.1 is atypical in that, in addition to including the provisions of a typical plan, it must undo the occupants' lifelong belief that elevators are not to be used in fire and similar emergencies. The message that the emergency plan needs to convey is that use of elevators is encouraged for occupant evacuation, but, if the elevators are called out of service before occupants can board them, occupants must be prepared to use the stairs. Note that 7.14.9.1 requires the occupant evacuation elevators to be within an occupant evacuation shaft system that provides direct access from the elevator lobby to an enclosed exit stair. It would be unsafe to rely on a system that encourages occupants to wait in an elevator lobby for an elevator and then forces them to re-enter other portions of the floor (e.g., a common exit access corridor) in order to reach an exit stair once elevators have been called out of service due to smoke breaching the occupant evacuation shaft system.

**7.14.3.1** Building occupants have traditionally been taught not to use elevators in fire or similar emergencies. The emergency action plan should include more than notification that the elevators can be used for emergency evacuation. The plan should include training to make occupants aware that the elevators will be available only for the period of time prior to elevator recall via smoke detection in the elevator lobby, elevator machine/control room or machinery/control space, or elevator hoistway. Occupants should be prepared to use the exit stairs, which are required to be directly accessible from the elevator lobby by 7.14.9.3, where the elevator has been called out of service.

**7.14.3.2** Occupant evacuation elevators shall be marked with signage indicating the elevators are suitable for use by building occupants for evacuation during fires.

The signage required by 7.14.3.2 is to be present on a day-to-day basis, rather than just under fire emergency, so as to inform occupants that the building elevator system differs from that in the majority of buildings — that is, those elevator systems for which the message has been ingrained by years of training that elevators are not to be used in fire emergencies. The required signage serves to help disseminate the information that 7.14.3.1 requires to be part of the emergency action plan. It replaces the signage currently required by ASME A17.1/CSA B44, *Safety Code for Elevators and Escalators*, that directs occupants to use stairs, and not elevators, in fire emergencies. Exhibit 7.202 shows a sign addressed by 7.14.3.2.

### 7.14.3.3 Conditions for Safe Continued Operation.

**7.14.3.3.1** Conditions necessary for the continued safe operation of the occupant evacuation elevators and the associated elevator lobbies and elevator machine rooms shall be continuously monitored and displayed at the building fire command center by a standard emergency service interface system meeting the

Exhibit 7.202

Elevator sign advising that elevator can be used in emergency. (Photo courtesy of Jake Pauls)

requirements of *NFPA 72, National Fire Alarm and Signaling Code*, and *NEMA SB 30, Fire Service Annunciator and Interface*.

**7.14.3.3.2** The monitoring and display required by 7.14.3.3.1 shall include all of the following:

- (1) Floor location of each elevator car
- (2) Direction of travel of each elevator car
- (3) Status of each elevator car with respect to whether it is occupied
- (4) Status of normal power to the elevator equipment, elevator controller cooling equipment, and elevator machine room ventilation and cooling equipment
- (5) Status of standby or emergency power system that provides backup power to the elevator equipment, elevator controller cooling equipment, and elevator machine/control room or machinery/control space ventilation and cooling equipment
- (6) Activation of any fire alarm–initiating device in any elevator lobby, elevator machine/control room or machinery/control space, or elevator hoistway

The standard emergency service interface system required by 7.14.3.3 is addressed in Annex E of *NFPA 72, National Fire Alarm and Signaling Code*, which reprints in its entirety *NEMA SB 30, Fire Service Annunciator and Interface*.<sup>25</sup>

The provision of 7.14.3.3.2 enumerates the conditions that must be monitored for the continued safe operation of the occupant evacuation elevators.

**7.14.3.4** The building fire command center location specified in 7.14.3.3.1 shall be provided with a means to override normal elevator operation and to initiate manually a Phase I emergency recall operation of the occupant evacuation elevators in accordance with ASME A17.1/CSA B44, *Safety Code for Elevators and Escalators*.

The provision of 7.14.3.4 helps to ensure that the emergency response personnel in the emergency command center can manually override normal elevator operation once the conditions necessary for the continued safe operation of the occupant evacuation elevators no longer exist. If the requirement of 7.14.3.4 were not part of Section 7.14, emergency response personnel would have to go to the street level elevator lobby to recall the elevators manually by using a special emergency services key.

#### 7.14.4 Fire Detection, Alarm, and Communication.

**7.14.4.1** The building shall be protected throughout by an approved fire alarm system in accordance with Section 9.6.

**7.14.4.2\*** The fire alarm system shall include an emergency voice/alarm communication system in accordance with *NFPA 72, National Fire Alarm and Signaling Code*, with the ability to provide voice directions on a selective basis to any building floor.

**A.7.14.4.2** The emergency voice/alarm communication system with the ability to provide voice directions on a selective basis to any building floor might be used to instruct occupants of the fire floor who are able to use stairs to relocate to a floor level below. The selective voice notification feature might be used to provide occupants of a given elevator lobby with a status report or supplemental instructions.

**7.14.4.3\*** The emergency voice/alarm communication system shall be arranged so that intelligible voice instructions are audible in the elevator lobbies under conditions where the elevator lobby doors are in the closed position.

**A.7.14.4.3** An audible notification appliance will need to be positioned in the elevator lobby in order to meet the requirement of 7.14.3.4. The continued use of the occupant evacuation elevator system is predicated on elevator lobby doors that are closed to keep smoke from reaching the elevator lobby smoke detector that is arranged to initiate the Phase I emergency recall operation.

**7.14.4.4 Two-way Communication System.** A two-way communication system shall be provided in each occupant evacuation elevator lobby for the purpose of initiating communication with the fire command center or an alternative location approved by the fire department.

**7.14.4.4.1 Design and Installation.** The two-way communication system shall include audible and visible signals and shall be designed and installed in accordance with the requirements of ICC/ANSI A117.1, *American National Standard for Accessible and Usable Buildings and Facilities*.

##### 7.14.4.4.2 Instructions.

**7.14.4.4.2.1** Instructions for the use of the two-way communication system, along with the location of the station, shall be permanently located adjacent to each station.

**7.14.4.4.2.2** Signage for instructions shall comply with the requirements of ICC/ANSI A117.1, *American National Standard for Accessible and Usable Buildings and Facilities*, for visual characters.

The provisions of 7.14.4.1 through 7.14.4.4.2.2 work together to provide occupants with initial notification of fire or similar emergency, continued detailed emergency voice instruction well into the emergency, and two-way communication capability to permit occupants to communicate with emergency responders. See A.7.14.4.2 and A.7.14.4.3 for guidance and examples on the use of emergency voice/alarm communication systems.

#### 7.14.5 Sprinklers.

**7.14.5.1** The building shall be protected throughout by an approved, supervised automatic sprinkler system in accordance with 9.7.1.1(1), except as otherwise specified in 7.14.5.1.1 through 7.14.5.3.

**7.14.5.1.1** A sprinkler control valve and a waterflow device shall be provided for each floor.

**7.14.5.1.2** The sprinkler control valves and waterflow devices required by 7.14.5.1.1 shall be monitored by the building fire alarm system.

**7.14.5.2\*** Sprinklers shall not be installed in elevator machine/control rooms and machinery/control spaces serving occupant evacuation elevators, and such prohibition shall not cause an otherwise fully sprinklered building to be classified as nonsprinklered.

**A.7.14.5.2** The presence of sprinklers in the elevator machine/control room or machinery/control space would necessitate the installation of a shunt trip for automatically disconnecting the main line power for compliance with ASME A17.1/CSA B44, *Safety Code for Elevators and Escalators*, as it is unsafe to operate elevators while sprinkler water is being discharged in the elevator machine/control room or machinery/control space. The presence of a shunt trip conflicts with the needs of the occupant evacuation elevator, as it disconnects the power without ensuring that the elevator is first returned to a safe floor so as to prevent trapping occupants.

**7.14.5.3\*** Where a hoistway serves occupant evacuation elevators, sprinklers shall not be installed at the top of the elevator hoistway or at other points in the hoistway more than 24 in. (610 mm) above the pit floor, and such prohibition shall not cause the building to be classified as nonsprinklered.

**A.7.14.5.3** NFPA 13, *Standard for the Installation of Sprinkler Systems*, permits sprinklers to be omitted from the top of the elevator hoistway where the hoistway for passenger elevators is noncombustible and the car enclosure materials meet the requirements of ASME A17.1/CSA B44, *Safety Code for Elevators and Escalators*. The provision of 7.14.5.3 restricts occupant evacuation elevators to passenger elevators that are in noncombustible

hoistways and for which the car enclosure materials meet the requirements of ASME A17.1/CSA B 44.

The presence of the sprinkler system required by 7.14.5.1 is a fundamental premise on which Section 7.14 is based. If the building were not sprinklered, it would not be safe for occupants to wait in elevator lobbies to evacuate via elevators.

The text of A.7.14.5.2 fully explains the rationale for prohibiting sprinklers from elevator machine rooms. The text of A.7.14.5.3 explains how the provisions of NFPA 13, *Standard for the Installation of Sprinkler Systems*,<sup>26</sup> and ASME A17.1/CSA B44, *Safety Code for Elevators and Escalators*, work together to permit the omission of sprinklers in the hoistway, except near the pit floor.

### 7.14.6 Elevator Installation.

**7.14.6.1** Except as modified by 7.14.6.2 and 7.14.6.3, occupant evacuation elevators shall be installed in accordance with ASME A17.1/CSA B44, *Safety Code for Elevators and Escalators*, including the provisions for occupant evacuation operation, as required by 7.14.1.3.

**7.14.6.2\*** Shunt breakers shall not be installed on elevator systems used for occupant evacuation.

**A.7.14.6.2** Elevator shunt breakers are intended to disconnect the electric power to an elevator prior to sprinkler system water-flow impairing the functioning of the elevator. The provision of 7.14.5.2 prohibits the installation of sprinklers in the elevator machine/control room or machinery/control space and at the top of the elevator hoistway, obviating the need for shunt breakers. The provision of 7.14.6.2 is not actually an exemption to the provisions of ASME A17.1/CSA B44, *Safety Code for Elevators and Escalators*, as ASME A17.1/CSA B44 requires the automatic main line power disconnect (shunt trip) only where sprinklers are located in the elevator machine/control room or machinery/control space or in the hoistway where it could cause unsafe elevator operation. The provision of 7.14.5.2 prohibits sprinklers in the elevator machine/control room and machinery/control space. The provision of 7.14.5.3 prohibits sprinklers at the top of the hoistway and at other points in the hoistway more than 24 in. (610 mm) above the pit floor in recognition of the limitations on combustibility established by 7.14.6.3.

**7.14.6.3** Occupant evacuation elevators shall be limited to passenger elevators that are located in noncombustible hoistways and for which the car enclosure materials meet the requirements of ASME A17.1/CSA B44, *Safety Code for Elevators and Escalators*.

The text of A.7.14.6.2 fully explains the rationale for prohibiting shunt breakers on elevator systems used for occupant evacuation.

The provision of 7.14.6.3 works with that of 7.14.5.3 to make it safe to permit the omission of sprinklers in the hoistway, except near the pit floor.

### 7.14.7 Elevator Machine/Control Rooms and Machinery/Control Spaces.

**7.14.7.1\*** Elevator machine/control rooms and machinery/control spaces associated with occupant evacuation elevators shall be separated from all building areas, other than elevator hoistways, by minimum 2-hour fire resistance-rated construction.

**A.7.14.7.1** The minimum 2-hour fire resistance-rated separation is based on the omission of sprinklers from the elevator machine room in accordance with 7.14.5.3.

**7.14.7.2\*** Elevator machine/control rooms and machinery/control spaces associated with occupant evacuation elevators shall be used for no purpose other than elevator machine/control rooms and machinery/control spaces.

**A.7.14.7.2** The requirement of 7.14.7.2 is consistent with that in ASME A17.1/CSA B44, *Safety Code for Elevators and Escalators*, which permits only machinery and equipment used in conjunction with the function or use of the elevator to be in the elevator machine/control room or machinery/control space. An inspection program should be implemented to ensure that the elevator machine/control room or machinery/control space is kept free of storage.

The provision of 7.14.7.1 works with that of 7.14.5.2 to ensure that the nonsprinklered elevator machine room is separated from all building areas, other than the elevator hoistway, by minimum 2-hour fire resistance-rated construction. The allowance for the elevator machine room to be open to the hoistway recognizes the functional need for cables to be connected between the motorized driver in the machine room and the elevator car in the hoistway. The minimum 2-hour fire resistance-rated separation required for the elevator machine room by 7.14.7.1 is consistent with that of 8.6.5(1) for the protection of vertical openings created by elevator hoistways that connect four or more stories in new construction.

The provision of 7.14.7.2 repeats a requirement of ASME A17.1/CSA B44, *Safety Code for Elevators and Escalators*, as it is important to remind the user not to store materials in the nonsprinklered elevator machine room. See 7.14.5.2 and A.7.14.5.2.

### 7.14.8 Electrical Power and Control Wiring.

**7.14.8.1** The following features associated with occupant evacuation elevators shall be supplied by both normal power and Type 60, Class 2, Level 1 standby power:

- (1) Elevator equipment
- (2) Ventilation and cooling equipment for elevator machine/control rooms and machinery/control spaces
- (3) Elevator car lighting

**7.14.8.2** Wires or cables that are located outside elevator hoistways, machine/control rooms, and machinery/control spaces, and that provide normal power, standby power, control signals, communication with the cars, lighting, heating, air-conditioning,

ventilation, and fire detecting systems to occupant evacuation elevators shall be protected by one of the following means, except as otherwise provided in 7.14.8.3:

- (1) The wiring shall utilize Type CI cable with a minimum 2-hour fire resistance rating.
- (2) The wiring shall be enclosed in a minimum 2-hour fire resistance construction.
- (3) The wiring shall be wiring that is approved as providing a 2-hour performance alternative.

Standby power is further addressed by NFPA 110, *Standard for Emergency and Standby Power Systems*. A Type 60 emergency power supply system (EPSS) must restore power within 60 seconds of the failure of the primary power source. A Class 2 EPSS must be capable of operating at its rated load without being refueled for a minimum of 2 hours. Level 1 performance is specified based on the technical committee's judgment that failure of the EPSS is critical to human life and safety. See NFPA 110.

The provision of 7.14.8.2 protects the elevator power wiring from a fire originating in any building area through which the wiring runs. Without such protection, a fire that is remote from the elevator hoistway and elevator lobbies might disable the power supply, preventing the elevators from being used for occupant evacuation.

**7.14.8.3\*** Control signaling wiring and cables that do not serve Phase II emergency in-car service shall not be required to be protected.

**A.7.14.8.3** Wiring or cables that provide control signals are exempt from the protection requirements of 7.14.8.2, provided that such wiring or cables, where exposed to fire, will not disable Phase II emergency in-car operation once such emergency operation has been activated.

### 7.14.9 Occupant Evacuation Shaft System.

**7.14.9.1** Occupant evacuation elevators shall be provided with an occupant evacuation shaft system consisting of all of the following:

- (1) Elevator hoistway
- (2) Enclosed elevator lobby outside the bank or group of hoistway doors on each floor served by the elevators, with the exception that elevator lobbies not be required to be enclosed where located either on the street floor or level of exit discharge
- (3) Enclosed exit stair with doors to all floors, at and above grade level, served by the elevators

#### 7.14.9.2\* Elevator Lobby Size.

**A.7.14.9.2** Elevator lobbies provide a safe place for building occupants to await the elevators and extend the time available for such use by providing a barrier to smoke and heat that might threaten the elevator car or hoistway. Smoke detectors within the elevator lobbies are arranged to initiate a Phase I emergency recall operation if the lobby is breached by smoke.

**7.14.9.2.1** Occupant evacuation elevator lobbies shall have minimum floor area, except as otherwise provided in 7.14.9.2.2, as follows:

- (1) The elevator lobby floor area shall accommodate, at 3 ft<sup>2</sup> (0.28 m<sup>2</sup>) per person, a minimum of 25 percent of the occupant load of the floor area served by the lobby.
- (2) The elevator lobby floor area also shall accommodate one wheelchair space of 30 in. × 48 in. (760 mm × 1220 mm) for each 50 persons, or portion thereof, of the occupant load of the floor area served by the lobby.

**7.14.9.2.2** The size of lobbies serving multiple banks of elevators shall be exempt from the requirement of 7.14.9.2.1(1), provided that the area of such lobbies is approved on an individual basis and is consistent with the building's emergency action plan.

**7.14.9.3** Access to the exit stair required by 7.14.9.1(3) shall be directly from the enclosed elevator lobby on each floor.

**7.14.9.4** The occupant evacuation shaft system shall be enclosed and separated from the remainder of the building by walls complying with the following:

- (1) The shaft system walls shall be smoke barriers in accordance with Section 8.5.
- (2) The shaft system walls separating the elevator lobby from the remainder of the building shall have a minimum 1-hour fire resistance rating and minimum ¾-hour fire protection-rated opening protectives.
- (3) The shaft system walls separating the elevator hoistway from the remainder of the building shall have a minimum 2-hour fire resistance rating and minimum 1½-hour fire protection-rated opening protectives.
- (4) The shaft system walls separating the enclosed exit stair from the remainder of the building shall have a minimum 2-hour fire resistance rating and minimum 1½-hour fire protection-rated opening protectives.

The occupant evacuation shaft system, as addressed in 7.14.9, provides the building construction features that support the occupant evacuation elevator system. The concepts on which the requirements for the occupant evacuation shaft system are based include the following:

1. The elevator hoistway must be served at each floor by an elevator lobby where building occupants can wait in safety for elevators.
2. An enclosed exit stair needs to be located immediately adjacent to, and directly accessible from, each elevator lobby to provide a means for occupant evacuation once elevators are called out of service.
3. The elevator hoistway, elevator lobby, and associated enclosed exit stair (i.e., the areas that comprise the occupant evacuation shaft system) need to be protected from fire originating outside the occupant evacuation shaft system.

4. Smoke from fire outside the occupant evacuation shaft system must not enter the occupant evacuation shaft system in sufficient quantity to initiate elevator recall via the smoke detectors in the elevator lobbies and hoistway.
5. Fire must not breach the occupant evacuation shaft system for the period of time that the elevators can be used effectively for occupant evacuation.
6. Each elevator lobby must be sized to accommodate the number of persons expected to need, or benefit from, the occupant elevator evacuation system.
7. Water from discharging sprinklers and fire fighter hose needs to be kept out of the hoistway to permit elevator equipment to continue operating safely.

**Exhibit 7.203** illustrates the occupant evacuation shaft system required by 7.14.9. The shaft system is the combined area of the hoistway, elevator lobby, and associated enclosed exit stair. Note that occupants of the elevator lobby have direct access to an enclosed exit stair without having to enter the corridor.

**7.14.9.5** Occupant evacuation shaft system enclosures shall be constructed to provide a minimum of classification Level 2 in accordance with ASTM C 1629/C 1629M, *Standard Classification for Abuse-Resistant Nondecorated Interior Gypsum Panel Products and Fiber-Reinforced Cement Panels*.

The provision of 7.14.9.5 helps to ensure that the barriers separating the occupant evacuation shaft system from the remainder of the floor include the impact resistance needed to withstand the challenges of day-to-day wear and tear. The test method cited, ASTM C 1629/C 1629M, *Standard Classification for Abuse-Resistant Nondecorated Interior Gypsum Panel Products and Fiber-Reinforced Cement Panels*,<sup>27</sup> was developed for gypsum panel products and fiber-reinforced cement products but can be applied to wall assemblies of any construction material. The standard directs that tests be run to demonstrate that the wall assembly has resistance to surface abrasion and indentation, including impact by soft and hard bodies.

**7.14.9.6\*** An approved method to prevent water from infiltrating into the hoistway enclosure from the operation of the automatic sprinkler system outside the enclosed occupant evacuation elevator lobby shall be provided.

**A.7.14.9.6** The performance-based language of 7.14.9.6 permits alternate design options to prevent water from an operating sprinkler system from infiltrating the hoistway enclosure. For example, such approved means might include drains and sloping the floor. The objective of the water protection requirement is to limit water discharged from sprinklers operating on the floor of fire origin from entering the hoistway, as it might by flowing into the lobby and under the landing doors, interfering with safety controls normally located on the front of the elevator car. A small flow of water (of the order of the flow from a single sprinkler) should be able to be diverted by the landing doorway nose plate to the sides of the opening, where it can do little harm. The

**Exhibit 7.203**

*Occupant evacuation shaft system separated from remainder of floor.*

requirement is intended to protect from water from sprinklers outside the elevator lobby, since the activation of sprinklers in the lobby would be expected to be preceded by activation of the lobby smoke detector that recalls the elevators.

Water protection can be achieved in any of several ways. Mitigation features that should be effective in keeping the water-flow from a sprinkler out of the hoistway include the following:

- (1) Raised lip in accordance with 7.1.6.2 and a floor drain
- (2) Sloped floor and a floor drain
- (3) Sealed sill plates and baseboards on both sides of the lobby partitions and along the perimeter of the hoistway shaft

The elevator hoistway must be protected from water infiltration at all sides, not just at the elevator hoistway door opening. Water from discharging sprinklers and fire fighter hose needs to be

kept out of the hoistway to permit elevator equipment to continue operating safely.

**7.14.9.7** Occupant evacuation shaft system elevator lobby doors, other than doors to the hoistway, exit stair enclosure, control room, or control space, shall have all of the following features:

- (1) The doors shall have a fire protection rating of not less than  $\frac{3}{4}$  hour.
- (2) The doors shall be smoke leakage-rated assemblies in accordance with NFPA 105, *Standard for Smoke Door Assemblies and Other Opening Protectives*.
- (3) The doors shall have an automatic positioning bottom seal to resist the passage of water at floor level from outside the shaft system.

The elevator lobby doors have a greater potential than the other elements of the occupant evacuation shaft system to permit smoke infiltration into the occupant evacuation shaft system, which would cause recall of the elevators via smoke detection in the elevator lobby. The elevator lobby doors on the fire floor will be opened and closed repeatedly as occupants move into the elevator lobby. However, when the doors are in the closed position, they are expected to properly retard the passage of smoke, as they must be smoke leakage-rated assemblies in accordance with NFPA 105, *Standard for the Installation of Smoke Door Assemblies and Other Opening Protectives*.

The requirement of 7.14.9.7(3) for an automatic-positioning bottom seal on elevator lobby doors introduces a door element not typically required by fire and life safety codes. The intent of the provision is explained via its performance-based requirement that the seal must resist the passage of water at floor level from outside the occupant evacuation shaft system.

**7.14.9.8** Occupant evacuation shaft system elevator lobby doors shall have the following features:

- (1) Each door, other than doors to the hoistway, exit stair enclosure, control room, or control space, shall be automatic-closing in accordance with 7.2.1.8.2, as modified by 7.14.9.8(2).
- (2) In addition to the automatic-closing means addressed by 7.2.1.8.2, the elevator lobby door on any floor shall also close in response to any alarm signal initiated on that floor.
- (3) Each door shall be provided with a vision panel arranged to allow people on either side of the door to view conditions on the other side of the door.

Elevator lobby doors are permitted to remain open on a normal, day-to-day basis but must be arranged to close automatically in accordance with 7.2.1.8.2 upon detection of smoke at the door opening and upon loss of electrical power. Furthermore, 7.14.9.8(2) includes a provision, in addition to those of 7.2.1.8.2, that requires the door to be released from its open position, so as to become self-closing, in response to any alarm signal initiated on that floor. The requirement is consistent with the intent of

many of the provisions of 7.14.9, which is to maintain the elevators in service by keeping smoke away from the elevator lobby smoke detectors.

**7.14.9.9** Each occupant evacuation shaft system exit stair enclosure door shall be provided with a vision panel arranged to allow people on either side of the door to view conditions on the other side of the door.

# Features of Fire Protection

**Chapter 8** establishes minimum requirements for features of fire protection, which include the following:

1. Construction
2. Compartmentation through use of fire barriers
3. Protection of vertical openings
4. Protection of concealed spaces
5. Subdivision of building spaces through use of smoke barriers and smoke partitions
6. Protection from hazards

This chapter specifies a menu of protection options that are mandated to varying degrees by specific occupancy chapters. Some of the provisions apply as requirements to all occupancies.

While the title suggests that the chapter encompasses any and all subject matter dealing with fire protection and fire safety, **Chapter 8** focuses on a number of passive building features that contribute to minimizing the impact of a fire on the building occupants. The bulk of this protection scheme is associated with a series of methods and techniques that are used to control the construction and compartmentation features of a building.

Managing the spread of a fire from the room of origin, or between floors in a building, is an important consideration. Managing the spread of fire through the construction of barriers designed to limit the transfer of heat, smoke, and, in some cases, both, is achieved by compartmentation. **Chapter 8** contains the minimum requirements for the construction of fire barriers, smoke barriers, and smoke partitions. These barriers are frequently used to enclose means of egress components, such as exit stairs, corridors, and exit passageways. For exit enclosures, the requirements of **Chapter 8** are applied in conjunction with those of **Chapter 7**, which imposes additional restrictions, since exits are considered “safe havens” within a building. The *Code* mandates that openings through or into separated areas be protected with appropriately rated doors, windows, or other devices that will prevent or minimize the spread of heat and other products of combustion into or through these areas.

Recognizing that there are acceptable, safe methods for permitting building spaces to be open to each other, **Chapter 8** addresses openings between floors, such as atria and mezzanines, which communicate among multiple floor levels of a building.

A building’s structural integrity during a fire is directly related to the fire resistance of its structural components. The *Code* regulates building construction in those occupancies where it is expected that evacuation will take an extended period of time (such as in assembly occupancies), or

where occupants will be defended in place (such as in health care occupancies), by specifying minimum types of construction for those occupancies in accordance with **Section 8.2**.

---

## 8.1 General

**8.1.1 Application.** The features of fire protection set forth in this chapter shall apply to both new construction and existing buildings.

Lack of compartmentation and rapid fire development have been significant factors in numerous multiple-fatality fires, especially in residential occupancies. Smoke spread throughout a floor not subdivided by smoke barriers has been identified as a factor contributing to loss of life in fires reported in health care occupancies. Unprotected vertical openings have repeatedly provided the route for fire spread in various occupancies. The ongoing role played by these factors in fires demonstrates the need to apply **Chapter 8** requirements to both new construction and existing buildings, as specified by **8.1.1**.

**8.1.2 Automatic Sprinkler Systems.** Where another provision of this chapter requires an automatic sprinkler system, the automatic sprinkler system shall be installed in accordance with the subparts of **9.7.1.1**, as permitted by the applicable occupancy chapter.

---

## 8.2 Construction and Compartmentation

The general requirements in **Section 8.2** aid in limiting the spread of smoke and fire and protect exit access corridors, exits, and other areas of the building from fire in adjoining areas and on other floors. Construction and compartmentation requirements vary by occupancy and are specified in **Chapters 12** through **42** of the *Code*.

To preserve the integrity of a fire or smoke compartment, all openings and penetrations for doors, ducts, and building services (e.g., electric power, telecommunications, water supply, and waste lines) must also be effectively closed or fitted with automatic closures. Equally important, and sometimes overlooked, are concealed spaces, particularly those above suspended ceilings, that frequently have been the means of spreading fire into otherwise protected areas.<sup>1</sup> In some instances, these interstitial spaces might be 8 ft (2440 mm) or more in

height; in others, they might serve as supply- or return-air plenums for heating, ventilating, and air-conditioning systems. Proper protection of concealed spaces can include firestopping, draftstopping, installation of automatic sprinklers, area limitations, and other limitations on the combustibility of contents, interior finishes, and construction materials. For specific concealed space protection details, see 8.6.11.

In Section 8.2, and throughout the *Code*, a distinction is made between smoke partitions, smoke barriers, and fire barriers. The function of a smoke partition and a smoke barrier is to restrict or minimize the passage of smoke, including fire gases. Fire barriers need to be reasonably airtight under increased air pressure on the fire side due to heated air expansion and must prevent the passage of heat and flame for a designated time. Fire barriers also must be capable of withstanding direct impingement by the fire, as determined by large-scale tests conducted in accordance with either of the following:

1. ASTM E 119, *Standard Test Methods for Fire Tests of Building Construction and Materials*<sup>2</sup>
2. ANSI/UL 263, *Standard for Fire Tests of Building Construction and Materials*<sup>3</sup>

In addition, doors in fire barriers must be capable of withstanding the effects of fire, as determined by large-scale tests in accordance with one of the following:

1. NFPA 252, *Standard Methods of Fire Tests of Door Assemblies*<sup>4</sup>
2. ANSI/UL 10B, *Standard for Fire Tests of Door Assemblies*<sup>5</sup>
3. ANSI/UL 10C, *Standard for Positive Pressure Fire Tests of Door Assemblies*<sup>6</sup>
4. NFPA 257, *Standard on Fire Test for Window and Glass Block Assemblies*<sup>7</sup>
5. ANSI/UL 9, *Standard for Fire Tests of Window Assemblies*<sup>8</sup>

Previous editions of the *Code* also referenced NFPA 251, *Standard Methods of Tests of Fire Resistance of Building Construction and Materials*<sup>9</sup>. That standard, however, was withdrawn by NFPA in 2010 to avoid duplication of the standards development activities of ASTM and UL.

## 8.2.1 Construction.

**8.2.1.1** Buildings or structures occupied or used in accordance with the individual occupancy chapters, Chapters 11 through 43, shall meet the minimum construction requirements of those chapters.

**8.2.1.2\*** NFPA 220, *Standard on Types of Building Construction*, shall be used to determine the requirements for the construction classification.

**A.8.2.1.2** Table A.8.2.1.2 is from NFPA 5000, *Building Construction and Safety Code*, and is reproduced in this annex for the convenience of users of this *Code*.

It is not the intent to require exterior walls to be protected against exterior fire exposure except where specifically required by NFPA 220 or NFPA 5000. Other building codes might also

require protection from the exterior in some circumstances. The presence of fire sprinklers or an occupiable exterior space, such as a porch or balcony, does not require protection against exterior fire exposure unless specifically required elsewhere.

The *Code* is not a building code. However, in certain occupancies, minimum construction requirements are established to help maintain structural integrity for the time needed for evacuation or relocation to a safe location in the building. In the case of health care occupancies, significant time is needed to ensure the safety of nonambulatory occupants; a safe fire and smoke compartment needs to be established within the building but protected from the compartment or zone of fire origin.

Minimum construction requirements are not mandated by 8.2.1; however, the detailed classification criteria of NFPA 220, *Standard on Types of Building Construction*, are referenced.<sup>10</sup> Therefore, construction types specified in other sections of the *Code* (particularly in Chapters 12 through 42 — the occupancy chapters) can use a shorthand notation, such as Type I(332), without additional, expansive detail. The user then refers to NFPA 220 for the necessary details. It is noted that the construction classification requirements of NFPA 220 are extracted from, and identical to, NFPA 5000®, *Building Construction and Safety Code*®<sup>11</sup>.

**8.2.1.3** Where the building or facility includes additions or connected structures of different construction types, the rating and classification of the structure shall be based on one of the following:

- (1) Separate buildings, if a 2-hour or greater vertically aligned fire barrier wall in accordance with NFPA 221, *Standard for High Challenge Fire Walls, Fire Walls, and Fire Barrier Walls*, exists between the portions of the building
- (2) Separate buildings, if provided with previously approved separations
- (3) Least fire-resistive construction type of the connected portions, if separation as specified in 8.2.1.3(1) or (2) is not provided

Some buildings are composed of sections and wings of differing construction types. For example, the portion of a building first constructed might be of Type III(200) (sometimes referred to as “ordinary”) construction; an addition might be of Type II(111) (noncombustible, 1-hour protected) construction; and the most recently added section of the building might be of Type V(000) (combustible, unprotected) construction (see Exhibit 8.1). Prior to the 2000 edition of the *Code*, it was left to the user and the authority having jurisdiction (AHJ) to determine the construction type classification assigned to a building with multiple construction types. The minimum fire resistance rating required of a vertically aligned fire barrier to create the equivalent of separate buildings, each of one construction type, is now specified by 8.2.1.3.

In Exhibit 8.1, Part (a), minimum 2-hour fire resistance-rated, vertically aligned fire barriers (i.e., walls, not floors) are provided

**Table A.8.2.1.2 Fire Resistance Ratings for Type I Through Type V Construction (hours)**

Construction Element	Type I		Type II			Type III		Type IV	Type V	
	442	332	222	111	000	211	200	2HH	111	000

H: Heavy timber members (see *NFPA 5000* for requirements).

<sup>a</sup>See 7.3.2.1 of *NFPA 5000*.

<sup>b</sup>See Section 7.3 of *NFPA 5000*.

<sup>c</sup>See 7.2.3.2.12, 7.2.4.2.3, and 7.2.5.6.8 of *NFPA 5000*.

[5000: Table 7.2.1.1]

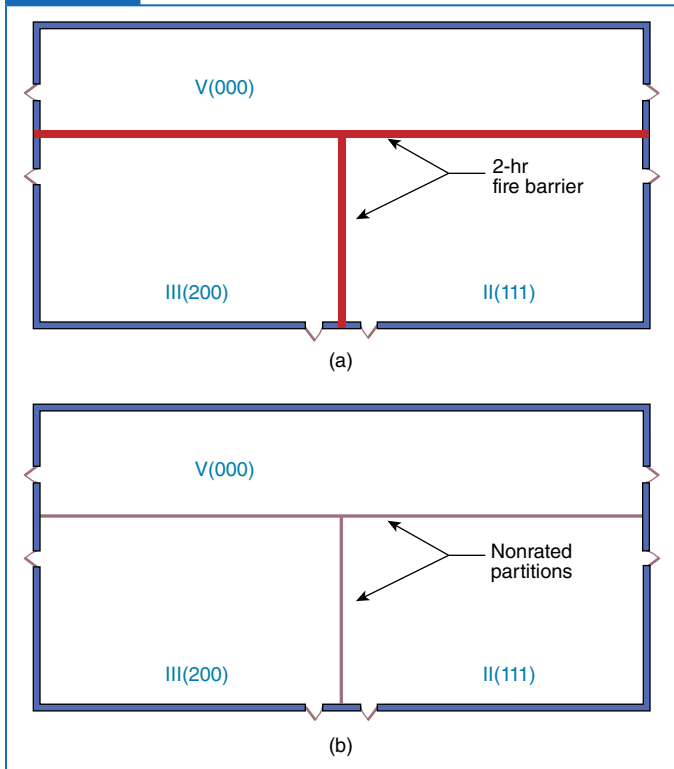

between the three portions of the building with differing construction types. For purposes of applying the minimum construction requirements, each section is permitted to be treated as a separate building; one building is of Type III(200) construction, a second building is of Type II(111) construction, and a third is of Type V(000) construction. In [Exhibit 8.1](#), Part (b), the non-rated partitions separating the portions of the building with differing construction types do not provide a minimum 2-hour fire resistance rating, so the building is classified as one building having the least fire resistance offered by any of the three construction types. Thus, the overall building construction is classified as Type V(000). Note that the fire barrier described in [8.2.1.3](#) creates “separate buildings” only for the purpose of determining construction classification.

[Table A.8.2.1.2](#) provides the *Code* user with a reprint of the key table from *NFPA 220, Standard on Types of Building Construction*, which is extracted from *NFPA 5000, Building Construction*

and *Safety Code*. The table summarizes portions of *NFPA 220* and *NFPA 5000*. The shorthand notation, such as Type I(332), provides the minimum hourly fire resistance ratings required to meet the definition of that construction type for only three components of the building — exterior bearing walls, structural frame/columns/girders, and floor construction. To meet the definition fully, other building components, such as roof construction and interior bearing walls, need to have certain minimum fire resistance ratings. Although it provides a summary of the fire resistance ratings for key structural elements, the shorthand notation alone does not provide all the needed information. *NFPA 220* or *NFPA 5000* should be consulted as necessary.

The minimum construction requirements of other sections of the *Code* might establish criteria, in addition to those of *NFPA 220*, for use in judging compliance with the definition of a specific building construction type. [Chapter 18](#), which is applicable to new health care occupancies, recognizes that an overall

**Exhibit 8.1**

*Building composed of sections with varying construction types.*

life safety package is necessary for a population that is incapable of self-preservation and, thus, is difficult to protect. Therefore, 18.1.6.4 requires that, for a building to be classified as either Type I or Type II construction, it must meet the requirements of NFPA 220 and have noncombustible or limited-combustible interior nonbearing walls (with modifications permitted for fire-retardant-treated wood — see 18.1.6.5). NFPA 220 does not address interior nonbearing walls.

Commentary Table 8.1 matches the various NFPA 220 and NFPA 5000 construction types with their approximate equivalent

construction types, as contained in the following model building codes that either have been previously used, or are currently in use throughout the United States:

1. *Uniform Building Code (UBC)*<sup>12</sup>
2. *BOCA National Building Code (B/NBC)*<sup>13</sup>
3. *Standard Building Code (SBC)*<sup>14</sup>
4. *International Building Code (IBC)*<sup>15</sup>

For example, a building that is classified by NFPA 220 and NFPA 5000 as Type II(111) is classified by the UBC as Type II 1 hour, by the B/NBC as Type 2B, by the SBC as Type IV 1 hour, and by the IBC as Type IIA.

When using the *Life Safety Code* in conjunction with one of these building codes, the authority having jurisdiction might consider using **Commentary Table 8.1** to establish corresponding construction classifications via the provision for equivalency in **Section 1.4**.

### 8.2.2 General.

**8.2.2.1** Where required by other chapters of this *Code*, every building shall be divided into compartments to limit the spread of fire and restrict the movement of smoke.

**8.2.2.2** Fire compartments shall be formed with fire barriers that comply with **Section 8.3**.

**8.2.2.3** Smoke compartments shall be formed with smoke barriers that comply with **Section 8.5**.

**8.2.2.4** Where door assemblies are required elsewhere in this *Code* to be smoke leakage-rated in accordance with 8.2.2.4, door assemblies shall comply with all of the following:

- (1) They shall be tested in accordance with ANSI/UL 1784, *Standard for Air Leakage Tests for Door Assemblies*.
- (2) The maximum air leakage rate of the door assembly shall be 3.0 ft<sup>3</sup>/min/ft<sup>2</sup> (0.9 m<sup>3</sup>/min/m<sup>2</sup>) of door opening at 0.10 in. water column (25 N/m<sup>2</sup>) for both the ambient and elevated temperature tests.

**Commentary Table 8.1 Cross-Reference of Building Construction Types**

NFPA 220/NFPA 5000	I(442)	I(332)	II(222)	II(111)	II(000)	III(211)	III(200)	IV(2HH)	V(111)	V(000)
UBC	—	I FR	II FR	II 1 hr	II N	III 1 hr	III N	IV HT	V 1 hr	V N
B/NBC	1A	1B	2A	2B	2C	3A	3B	4	5A	5B
SBC	I	II	—	IV 1 hr	IV UNP	V 1 hr	V UNP	III	VI 1 hr	VI UNP
IBC	—	IA	IB	IIA	IIB	IIIA	IIIB	IV HT	VA	VB

UBC — *Uniform Building Code*.  
 B/NBC — *National Building Code*.  
 SBC — *Standard Building Code*.  
 UNP — Unprotected.  
 IBC — *International Building Code*.

- (3) Door assemblies shall be installed and maintained in accordance with NFPA 105, *Standard for Smoke Door Assemblies and Other Opening Protectives*.

Minimum criteria for air leakage rates of door assemblies are specified by 8.2.2.4 to provide a smoketight assembly. However, the criteria in 8.2.2.4 are mandatory only when referenced by another section of the Code — such as in Chapters 12 through 42. New fire doors serving areas of refuge are required to meet the 8.2.2.4 air-leakage rate criteria (see 7.2.12.3.4.1).

### 8.2.3 Fire Resistance–Rated Construction.

**8.2.3.1\*** The fire resistance of structural elements and building assemblies shall be determined in accordance with test procedures set forth in ASTM E 119, *Standard Test Methods for Fire Tests of Building Construction and Materials*, or ANSI/UL 263, *Standard for Fire Tests of Building Construction and Materials*; other approved test methods; or analytical methods approved by the authority having jurisdiction.

**A.8.2.3.1** ASTM E 119, *Standard Test Methods for Fire Tests of Building Construction and Materials*, and ANSI/UL 263, *Standard for Fire Tests of Building Construction and Materials*, are considered nationally recognized methods of determining fire resistance and have been found to yield equivalent test results.

**8.2.3.1.1** Materials used to construct fire resistance–rated elements and assemblies shall be limited to those permitted in this Code.

**8.2.3.1.2** In new construction, end-jointed lumber used in an assembly required to have a fire resistance rating shall have the designation “Heat Resistant Adhesive” or “HRA” included in its grade mark.

End-jointed lumber, also known as finger-jointed lumber, is manufactured by gluing together shorter segments of lumber, end-to-end, with fingerlike joints. An auditing program of the American Lumber Standards Committee requires marking of end-jointed lumber with a designation of either “HRA” (heat-resistant adhesive) or “Non-HRA” (non-heat-resistant adhesive). The requirement of 8.2.3.1.2 ensures that, for new construction, the adhesive meets performance requirements at elevated temperatures as specified by one of the following standards:

1. ASTM D 7374, *Practice for Evaluating Elevated Temperature Performance of Adhesives Used in End-Jointed Lumber*<sup>16</sup>
2. ASTM D 7470, *Practice for Evaluating Elevated Temperature Performance of End-Jointed Lumber*<sup>17</sup>

**8.2.3.2** Fire resistance–rated floor and roof assemblies shall be classified as restrained or unrestrained in accordance with ASTM E 119, *Standard Test Methods for Fire Tests of Building Construction and Materials*, or ANSI/UL 263, *Standard for Fire Tests of Building Construction and Materials*; or other approved

test methods. The construction shall be considered restrained only where a registered design professional has furnished the authority having jurisdiction with satisfactory documentation verifying that the construction is restrained. The classification of fire resistance–rated floor and roof construction shall be identified on the plans as restrained or unrestrained.

The fire resistance of a fire barrier is determined by the test method described in ASTM E 119, *Standard Test Methods for Fire Tests of Building Construction and Materials*, and ANSI/UL 263, *Standard for Fire Tests of Building Construction and Materials*. The ASTM E 119 and ANSI/UL 263 test standards provide for the rating of the construction of the particular assembly and the actual testing of the assembly in the test furnace. The test is conducted under very rigid conditions, so that test results on the same assembly are reproducible, and tests of different assemblies are comparable. During the test, the assembly being tested is loaded the same way it would be expected to be loaded where installed in a building. Temperatures in the furnace are generated in strict accordance with the standard time–temperature curve and reach levels of 1000°F (538°C), 1300°F (704°C), 1550°F (843°C), 1700°F (927°C), 1850°F (1010°C), and 2000°F (1093°C) at intervals of 5, 10, 30, 60, 120, and 240 minutes into the test, respectively. Temperatures both in the furnace and on the unexposed side of the assembly being tested are monitored, and results are recorded at specified intervals and locations. During the course of the test, cotton waste is placed against the unexposed surface and observed for flaming.

The acceptance criteria for a successfully completed fire test on an assembly for a specified time period follow:

1. The cotton waste on unexposed side does not ignite.
2. The temperature rise on unexposed side does not exceed 325°F (180°C) at any point or an average of 250°F (139°C).
3. The assembly continues to support design loads.

The criteria in items 1 through 3 apply to floor, roof, wall, and partition assemblies. In addition, wall and partition assemblies that are to be rated at 1 hour or more are subjected to the hose stream test. A duplicate specimen of the assembly to be rated is tested in the furnace for one-half the time specified as the fire resistance rating in the fire endurance test. This specimen is then removed from the furnace and immediately subjected to the hose stream test. If there is any projection of water beyond the unexposed surface, the assembly is considered to have failed.

Testing laboratories commonly perform the ASTM E 119 and ANSI/UL 263 testing. The laboratories normally issue a report of the test and then list or approve the assembly. Listings of tested fire resistance–rated assemblies are found in publications and on websites of laboratories that conduct fire testing, such as the following:

1. *UL Fire Resistance Directory*<sup>18</sup>
2. *FM Approval Guide*<sup>19</sup>

3. *Intertek Directory of Listed Products* [contains all listings for ETL, Warnock Hersey (WHI), and Omega Point Laboratories (OPL)<sup>20</sup>]

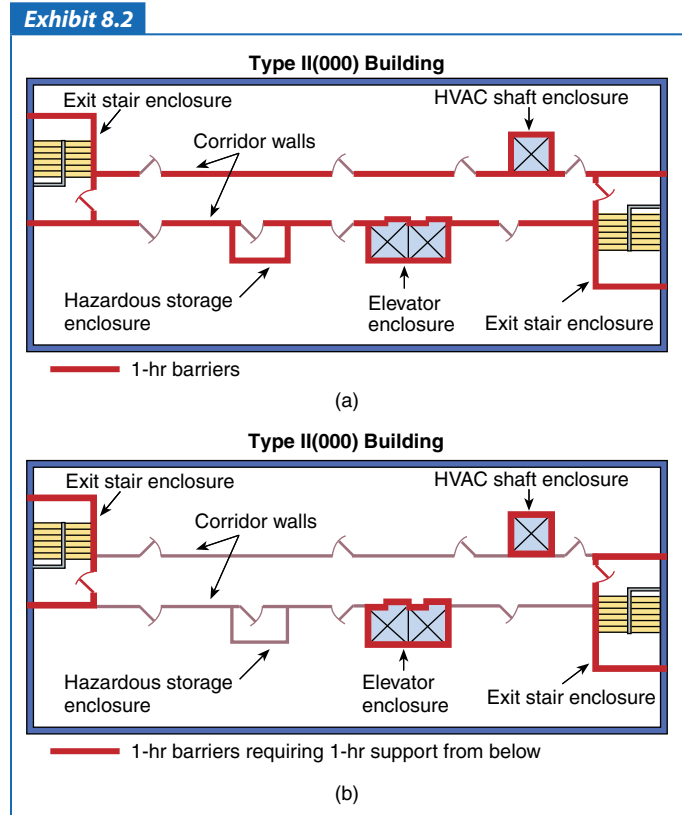

It is important that the assembly constructed in the field is the same as that listed or approved. For example, if a floor/ceiling assembly calls for clips on the ceiling tiles, the clips must be installed and maintained. Another example is the special treatment often required for lights or air ducts in suspended ceilings. A common problem in walls is the installation of an untested material between the wallboard and the studs or the installation of recessed wall fixtures, which requires the removal of wallboard.

**8.2.3.3** Structural elements that support fire barriers shall be permitted to have only the fire resistance rating required for the construction classification of the building, provided that both of the following criteria are met:

- (1) Such structural elements support nonbearing wall or partition assemblies that have a required 1-hour fire resistance rating or less.
- (2) Such structural elements do not serve as exit enclosures or protection for vertical openings.

If **8.2.3.3** were not included in the *Code*, a two-story building, for example, used for an occupancy that (1) permits Type II(000) construction to be occupied and (2) requires the presence of 1-hour fire resistance-rated corridor walls, would be required to upgrade all construction supporting the nonbearing second-floor corridor walls (i.e., the columns, beams, and girders supporting the second floor) to a 1-hour fire resistance rating. Because the purpose of 1-hour-rated corridor walls is not to provide structural integrity but to provide barriers that create fire compartments on the floor on which they are installed, **8.2.3.3** permits the unprotected, noncombustible Type II(000) building to be occupied in accordance with the 18.1.6 subsection of the applicable occupancy chapter.

**Exhibit 8.2** further illustrates the use of **8.2.3.3**. The floor shown in Part (a) is the second floor of a two-story building that, given its occupancy, is permitted to be in a building of Type II(000) construction, as defined by NFPA 220, *Standard on Types of Building Construction* (see **A.8.2.1.2** and its associated commentary). In addition, the occupancy in question requires (1) corridor walls with a 1-hour fire resistance rating, and (2) enclosure of hazardous area rooms, interior exit stairs, and vertical openings, such as elevator and ventilating (HVAC) shafts, by 1-hour fire resistance-rated barriers. As shown in Part (b) of **Exhibit 8.2**, **8.2.3.3** permits the building construction that supports the second-floor corridor walls and the walls enclosing the hazardous storage room to remain unprotected, but such construction is to be noncombustible, as specified by building construction Type II(000). However, the second-floor 1-hour-rated fire barriers enclosing the exit stairs, and the elevator shaft and the HVAC shaft, must be supported by 1-hour fire resistance-rated construction. In Part (b), only those fire barriers depicted by bold, red lines are required to be supported by 1-hour-rated construction from below.

*Fire barriers and rated structural supports.*

**8.2.3.4** The requirement of **8.2.3.3** shall not apply to health care occupancy structural elements supporting floor assemblies in accordance with the provisions of **18.1.6** and **19.1.6**.

## 8.2.4 Analytical Methods.

**8.2.4.1** Analytical methods utilized to determine the fire resistance rating of building assemblies shall comply with **8.2.4.2** through **8.2.4.5**.

**8.2.4.2\*** Where calculations are used to establish the fire resistance rating of structural elements or assemblies, they shall be permitted to be performed in accordance with ASCE/SFPE 29, *Standard Calculation Methods for Structural Fire Protection*.

**A.8.2.4.2** The intent of this provision is to allow the provisions of either ASCE/SFPE 29, *Standard Calculation Methods for Structural Fire Protection*, or ACI 216.1/TMS 0216.1 *Code Requirements for Determining Fire Resistance of Concrete and Masonry Construction Assemblies*, for the calculation for fire resistance of concrete or masonry elements or assemblies.

**8.2.4.3** Where calculations are used to establish the fire resistance rating of concrete or masonry elements or assemblies, the provisions of ACI 216.1/TMS 0216.1, *Code Requirements for Determining Fire Resistance of Concrete and Masonry Construction Assemblies*, shall be permitted to be used.

**8.2.4.4** Except for the methods specified in 8.2.4.2 and 8.2.4.3 analytical methods used to calculate the fire resistance of building assemblies or structural elements shall be approved.

**8.2.4.5** Where an approved analytical method is utilized to establish the fire resistance rating of a structural element or building assembly, the calculations shall be based upon the fire exposure and acceptance criteria specified in ASTM E 119, *Standard Test Methods for Fire Tests of Building Construction and Materials*, or ANSI/UL 263, *Standard for Fire Tests of Building Construction and Materials*.

Analytical methods are alternate methods of determining the fire resistance ratings of construction assemblies in lieu of the large-scale test in accordance with ASTM E 119 or ANSI/UL 263, as specified in 8.2.3.1. For example, a designer who wants to provide a 2-hour fire resistance rating for a W14 × 233 steel column by boxing the column with gypsum wallboard is unable to find such an assembly in the *UL Fire Resistance Directory*. Design No. X520 and design No. X521 come very close to providing the needed information but deal with W14 × 228 steel columns; the designs show that, with one layer of ½ in. (13 mm) thick gypsum wallboard, the assembly will provide a 2-hour fire resistance rating. The *UL Fire Resistance Directory* further explains that most structural steel producers began rolling a new series of structural shapes in accordance with ASTM A 6/A6M, *Standard Specification for General Requirements for Rolled Structural Steel Bars, Plates, Shapes, and Sheet Piling*,<sup>21</sup> in 1978 and that some of the column sizes specified for individual designs might have been discontinued. Instead of attempting to judge whether the W14 × 233 column will provide the same rating as the discontinued W14 × 228 shape by comparing flange and web thickness, the designer calculates the fire resistance rating of a W14 × 233 steel column with a single layer of ½ in. (13 mm) gypsum wallboard built around the column in a box profile using criteria from ASCE/SFPE 29, *Standard Calculation Methods for Structural Fire Protection*,<sup>22</sup> as referenced in 8.2.4.2.

Based on results from accumulated fire test data, ASCE/SFPE 29 presents the following formula for calculating the fire endurance of steel columns protected by gypsum wallboard:

$$R = 2.17 \left[ \frac{h(W')}{2} \right]^{0.75}$$

where

$R$  = fire resistance (hr)

$h$  = thickness of gypsum wallboard (in.)

$W'$  = weight of steel column and gypsum wallboard protection (lb/ft)

$D$  = heated perimeter of steel column (in.) [for box profile, inside perimeter of gypsum wallboard material, calculated as  $D = 2(a + b)$  per Exhibit 8.3]

The total weight ( $W'$ ) of both the column and its gypsum wallboard protection is calculated using the following formula:

$$W' = \frac{W + 50(h)(D)}{144}$$

where  $W$  = weight of steel column (lb/ft)

Performing the calculations yields the following:

$$\begin{aligned} D &= 2(a + b) \\ &= 2(15.89 + 16.04) \\ &= 63.86 \text{ in.} \\ W' &= \frac{W + 50(h)(D)}{144} \\ &= 233 + \frac{50(0.5)(63.86)}{144} \\ &= 244.09 \text{ lb/ft} \\ \frac{W'}{D} &= \frac{244.09}{63.86} = 3.82 \\ &= 2.17 \left[ \frac{h(W')}{2} \right]^{0.75} \\ &= 2.17 \left[ \frac{(0.50)(3.82)}{2} \right]^{0.75} \\ &= 2.1 \text{ hr} \end{aligned}$$

Based on the calculation for fire endurance, the designer specifies, with a degree of comfort, that the 2-hour fire resistance rating for the assembly consisting of the W14 × 233 steel column and gypsum wallboard box profile enclosure be achieved using a single layer of ½ in. (13 mm) gypsum wallboard.

In addition to calculation methods for determining the fire resistance of structural steel construction, ASCE/SFPE 29 includes

**Exhibit 8.3**

Box profile of gypsum wallboard around steel column for which fire resistance rating of assembly can be calculated.

calculation methods for plain and reinforced concrete construction, timber and wood structural elements, and masonry construction. Alternatively, the designer is permitted to use the American Concrete Institute standard ACI 216.1/TMS O216.1, *Code Requirements Determining Fire Resistance of Concrete and Masonry Construction Assemblies*<sup>23</sup>, to calculate the fire resistance of concrete and masonry construction assemblies. The authority having jurisdiction must approve calculation methods other than those described in the ASCE and ACI standards, as specified in 8.2.4.4.

## 8.3 Fire Barriers

### 8.3.1 General.

**8.3.1.1** Fire barriers used to provide enclosure, subdivision, or protection under this *Code* shall be classified in accordance with one of the following fire resistance ratings:

- (1) 3-hour fire resistance rating
- (2) 2-hour fire resistance rating
- (3) 1-hour fire resistance rating
- (4)\* ½-hour fire resistance rating

**A.8.3.1.1(4)** Walls in good condition with lath and plaster, or gypsum board of not less than ½ in. (13 mm) on each side, can be considered as providing a minimum ½-hour fire resistance rating. Additional information on archaic material assemblies can be found in Annex O of NFPA 914, *Code for Fire Protection of Historic Structures*.

Fire resistance testing of building construction per ASTM E 119 or ANSI/UL 263 permits assemblies to be assigned fire resistance ratings up through the category of “8 hours and over.” Ratings of more than 2 hours are used primarily in protecting property; however, some occupancy separations require 3-hour fire barriers per Table 6.1.14.4.1(a) and Table 6.1.14.4.1(b). The *Code* requires not more than a 2-hour fire resistance rating for building construction, even in the health care and detention and correctional occupancy chapters. These chapters promote a defend-in-place strategy, because such a strategy emphasizes life safety over property protection. Thus, in the \_\_\_ .1.6 subsections in the health care and detention and correctional occupancy chapters, construction Types I(442), I(332), and II(222) are grouped to be treated as equivalent. A design professional can specify that material assemblies with 3-hour or 4-hour fire resistance ratings be used. However, no reduction in requirements is permitted other than those permitted for construction with a 2-hour fire resistance rating.

Prior to the 1997 edition, the *Code* included ¾-hour and ½-hour fire resistance rating classifications in addition to the current ½-hour classification. The range of fractional-hour ratings mistakenly implied a degree of accuracy and precision. The range was revised so that the only fire resistance rating of less than 1 hour is the ½-hour classification. Because some

occupancies, such as existing health care occupancies, previously permitted a fire resistance rating of ⅓ hour but now require a rating of ½ hour, A.8.3.1.1(4) provides guidance on evaluating existing fire barriers. The change from the ⅓-hour to the ½-hour classification was not intended to create a condition of noncompliance where existing fire barriers had previously complied with *Code* requirements. A previously approved ⅓-hour fire resistance-rated barrier should be considered as complying with the requirement for a ½-hour fire barrier.

**8.3.1.2\*** Fire barriers shall comply with one of the following:

- (1) The fire barriers are continuous from outside wall to outside wall or from one fire barrier to another, or a combination thereof, including continuity through all concealed spaces, such as those found above a ceiling, including interstitial spaces.
- (2) The fire barriers are continuous from outside wall to outside wall or from one fire barrier to another, and from the floor to the bottom of the interstitial space, provided that the construction assembly forming the bottom of the interstitial space has a fire resistance rating not less than that of the fire barrier.

**A.8.3.1.2** To ensure that a fire barrier is continuous, it is necessary to seal completely all openings where the fire barrier abuts other fire barriers, the exterior walls, the floor below, and the floor or ceiling above. In 8.3.1.2(2), the fire resistance rating of the bottom of the interstitial space is provided by that membrane alone. Ceilings of rated floor/ceiling and roof/ceiling assemblies do not necessarily provide the required fire resistance.

In Exhibit 8.4, the bold, red lines designate a variety of fire barriers that meet the requirement of horizontal continuity to prevent a fire from spreading around the end of the barrier into the adjoining fire compartment.

Fire barrier A divides the building into two distinct fire compartments by extending continuously from an outside wall to an outside wall. This barrier could have, but does not have, door openings that would be protected by fire protection-rated door assemblies meeting the requirements of 8.3.4. Fire barrier B further subdivides the building into a third fire compartment and achieves its required horizontal continuity by running from an outside wall to a fire barrier (barrier A). The door opening is permitted if protected by an appropriately rated fire door assembly.

The fire barriers surrounding room C meet the horizontal continuity requirement by running from one fire barrier to another fire barrier to another; they envelop the room. This arrangement is commonly used to isolate a room and, thus, meet the protection requirements associated with protecting a hazardous area, such as a storage room or mechanical equipment room, as specified by the applicable occupancy chapter.

Fire barriers are often used to meet the protection and isolation requirements associated with corridors. Corridor D is protected by fire barriers that run from an outside wall to a fire barrier, to another fire barrier, to an outside wall. They isolate the

Exhibit 8.4

Typical fire barriers

corridor from other spaces on the floor and meet the horizontal continuity requirements.

In addition to horizontal continuity, fire barriers are required to be vertically continuous through all interstitial spaces, as described in 8.3.1.2(1).

In some cases, interstitial spaces above ceilings and between floors contain a considerable fuel load and are readily accessible. The possibility that an interstitial space will be used for storage should not be overlooked. These factors must be considered to determine whether an interstitial space is, in fact, another floor. See Exhibit 7.11, which illustrates an exit enclosure and egress provision of Chapter 7 but also shows interstitial spaces that constitute the equivalent of separate floors.

In lieu of a fire barrier being vertically continuous through the interstitial spaces to the underside of the floor or roof above, 8.3.1.2(2) permits it to terminate at the ceiling, but only where the ceiling membrane, by itself, provides a fire resistance rating equivalent to that required for the fire barrier.

Ceilings are typically tested as part of a floor/ceiling or roof/ceiling assembly, rather than tested alone. The test does not indicate the performance of the ceiling by itself but, rather, the performance of the total assembly. For example, the ceiling of a 1-hour floor/ceiling assembly might experience failure in a fire in less than 20 minutes, but the overall assembly might pass the 1-hour test. A designer or contractor might refer to a 1-hour or 2-hour ceiling and request permission to terminate a fire barrier at the ceiling, but, in reality, the ceiling is part of a 1-hour or 2-hour floor/ceiling or roof/ceiling assembly. Because the ceiling itself does not provide the appropriately rated fire barrier against which the wall assembly can be terminated, the fire barrier must run through and above the ceiling; it must extend from the floor to the underside of the floor or roof above.

Tests reported by the Gypsum Association in the *Fire Resistance Design Manual* indicate that two layers of  $\frac{5}{8}$  in. (16 mm),

fire-rated, Type X gypsum wallboard, applied at right angles to the underside of 2 in.  $\times$  10 in. nominal (38 mm  $\times$  254 mm actual) wood joists and spaced 24 in. (610 mm) on centers, with the face layer of the gypsum board offset by 24 in. (610 mm) from the base layer joints, will provide 1-hour fire resistance protection for the wood framing.<sup>24</sup> Using this information, the authority having jurisdiction might judge that such a ceiling meets the intent of 8.3.1.2(2) and could permit a 1-hour fire resistance-rated wall assembly to terminate tightly against the underside of such a ceiling.

Part (a) of Exhibit 8.5 depicts a 1-hour fire barrier wall assembly continuing up through the ceiling and void space of a 1-hour fire resistance-rated floor/ceiling assembly, so as to terminate tightly against the underside of the floor slab to achieve the required vertical continuity. (Although, in this example, the floor/ceiling assembly has a 1-hour fire resistance rating, such a rating is not necessarily required.) In Exhibit 8.5, Part (b), 8.3.1.2(2) is used to permit the 1-hour-rated fire barrier wall assembly to terminate at a ceiling that, by itself, provides the required 1-hour fire resistance rating.

**8.3.1.3** Walls used as fire barriers shall comply with Chapter 7 of NFPA 221, *Standard for High Challenge Fire Walls, Fire Walls, and Fire Barrier Walls*. The NFPA 221 limitation on percentage width of openings shall not apply.

The requirement in 8.3.1.3 that fire barrier walls must meet NFPA 221, *Standard for High Challenge Fire Walls, Fire Walls, and Fire Barrier Walls*,<sup>25</sup> recognizes that the NFPA technical committee responsible for the development of NFPA 221 has specialized expertise in this area. The detailed provisions of NFPA 221 for fire barrier

Exhibit 8.5

Fire barrier vertical continuity.

walls include requirements that are outside the scope of this Code but that are necessary to ensure the intended level of protection.

### 8.3.2 Walls.

**8.3.2.1** The fire-resistive materials, assemblies, and systems used shall be limited to those permitted in this Code and this chapter.

**8.3.2.1.1\*** Fire resistance-rated glazing tested in accordance with ASTM E 119, *Standard Test Methods for Fire Tests of Building Construction and Materials*, or ANSI/UL 263, *Standard for Fire Tests of Building Construction and Materials*, shall be permitted.

**A.8.3.2.1.1** Fire resistance-rated glazing complying with 8.3.2, where not installed in a door, is considered a wall, not an opening protective.

**8.3.2.1.2** New fire resistance-rated glazing shall bear the identifier “W-XXX” where “XXX” is the fire resistance rating in minutes. Such identification shall be permanently affixed.

The provisions of 8.3.2.1.1 and 8.3.2.1.2 recognize that glazing material that has been tested as a wall assembly in accordance with ASTM E 119 or ANSI/UL 263 is permitted to be used in fire barrier walls with no limitations, other than those imposed by the product’s listing. New glazing material tested and used as such must be appropriately labeled as specified in 8.3.2.1.2.

**8.3.2.2** The construction materials and details for fire-resistive assemblies and systems for walls described shall comply with all other provisions of this Code, except as modified herein.

**8.3.2.3** Interior walls and partitions of nonsymmetrical construction shall be evaluated from both directions and assigned a fire resistance rating based on the shorter duration obtained in accordance with ASTM E 119, *Standard Test Methods for Fire Tests of Building Construction and Materials*, or ANSI/UL 263, *Standard for Fire Tests of Building Construction and Materials*. When the wall is tested with the least fire-resistive side exposed to the furnace, the wall shall not be required to be subjected to tests from the opposite side.

### 8.3.3 Fire Doors and Windows.

**8.3.3.1** Openings required to have a fire protection rating by Table 8.3.4.2 shall be protected by approved, listed, labeled fire door assemblies and fire window assemblies and their accompanying hardware, including all frames, closing devices, anchorage, and sills in accordance with the requirements of NFPA 80, *Standard for Fire Doors and Other Opening Protectives*, except as otherwise specified in this Code.

**8.3.3.1.1** Fire resistance-rated glazing tested in accordance with ASTM E 119, *Standard Test Methods for Fire Tests of Building Construction and Materials*, or ANSI/UL 263, *Standard for Fire Tests of Building Construction and Materials*, shall be permitted in fire door assemblies and fire window assemblies where tested and installed in accordance with their listings.

**8.3.3.1.2** New fire resistance-rated glazing shall be marked in accordance with Table 8.3.3.12 and Table 8.3.4.2. Such marking shall be permanently affixed.

**8.3.3.2\*** Fire protection ratings for products required to comply with 8.3.3 shall be as determined and reported by a nationally recognized testing agency in accordance with NFPA 252, *Standard Methods of Fire Tests of Door Assemblies*; ANSI/UL 10B, *Standard for Fire Tests of Door Assemblies*; ANSI/UL 10C, *Standard for Positive Pressure Fire Tests of Door Assemblies*; NFPA 257, *Standard on Fire Test for Window and Glass Block Assemblies*; or ANSI/UL 9, *Standard for Fire Tests of Window Assemblies*.

**A.8.3.3.2** Some door assemblies have been tested to meet the conditions of acceptance of ASTM E 119, *Standard Test Methods for Fire Tests of Building Construction and Materials*, or ANSI/UL 263, *Standard for Fire Tests of Building Construction and Materials*. Where such assemblies are used, the provisions of 8.3.2 should be applied instead of those of 8.3.3.2.

**8.3.3.2.1** Fire protection-rated glazing shall be evaluated under positive pressure in accordance with NFPA 257, *Standard on Fire Test for Window and Glass Block Assemblies*.

**8.3.3.2.2** All products required to comply with 8.3.3.2 shall bear an approved label.

#### 8.3.3.2.3\* Labels.

**A.8.3.3.2.3** In existing installations, it is important to be able to determine the fire protection rating of the fire door. However, steel door frames that are well set in the wall might be judged as acceptable even if the frame label is not legible.

**8.3.3.2.3.1** Labels on fire door assemblies shall be maintained in a legible condition.

**8.3.3.2.3.2** In existing installations, steel door frames without a label shall be permitted where approved by the authority having jurisdiction.

**8.3.3.3** Unless otherwise specified, fire doors shall be self-closing or automatic-closing in accordance with 7.2.1.8.

Fire protection-rated door assemblies are tested in accordance with NFPA 252, *Standard Methods of Fire Tests of Door Assemblies*. Such assemblies must be installed in accordance with the requirements of NFPA 80, *Standard for Fire Doors and Other Opening Protectives*.<sup>26</sup> Where the Code uses the term *door*, it includes not only the door leaf or slab but also the doorway, frame, and necessary hardware, including hinges. Where describing a fire door, the applicable standards similarly define a fire protection-rated assembly as including all these components, as well as a listed door closer and positive latching.

If they are to be effective, fire doors must be not only closed but also held closed. Building fires are capable of generating pressures sufficient to force fire doors open if they are not held closed with positive latching, thereby rendering the doors incapable of protecting the opening in which they are installed.

The acceptance criteria for fire protection–rated assemblies, such as fire doors, differ from those for fire resistance–rated construction, such as a wall or floor/ceiling assembly. The limitation of temperature rise through the fire door is not normally a measure of acceptance, although it is a measure of acceptance for a fire resistance–rated assembly such as a wall. In addition, during the course of the fire test, fire doors will expand on the exposed side and, as a result, will warp — sometimes expanding through the door opening at the top of the door. This expansion and warping can result in some flaming through the top of the door openings. The test standards recognize this phenomenon, and a certain amount of such flaming is permitted under the acceptance criteria. This does not adversely affect safety, given that fire protection–rated assemblies are intended to protect relatively small openings in larger fire resistance–rated barriers. Also, to maintain the door as usable, combustible materials are not typically stored in front of the door opening.

**8.3.3.4** Floor fire door assemblies shall be tested in accordance with NFPA 288, *Standard Methods of Fire Tests of Horizontal Fire Door Assemblies Installed in Horizontal Fire Resistance–Rated Assemblies*, and shall achieve a fire resistance rating not less than the assembly being penetrated. Floor fire door assemblies shall be listed and labeled.

**8.3.3.5** Fire protection–rated glazing shall be permitted in fire barriers having a required fire resistance rating of 1 hour or less and shall be of an approved type with the appropriate fire protection rating for the location in which the barriers are installed.

**8.3.3.6\*** Glazing in fire window assemblies, other than in existing fire window installations of wired glass and other fire-rated glazing material, shall be of a design that has been tested to meet the conditions of acceptance of NFPA 257, *Standard on Fire Test for Window and Glass Block Assemblies*, or ANSI/UL 9, *Standard for Fire Tests of Window Assemblies*. Fire protection–rated glazing in fire door assemblies, other than in existing fire-rated door assemblies, shall be of a design that has been tested to meet the conditions of acceptance of NFPA 252, *Standard Methods of Fire Tests of Door Assemblies*; ANSI/UL 10B, *Standard for Fire Tests of Door Assemblies*; or ANSI/UL 10C, *Standard for Positive Pressure Fire Tests of Door Assemblies*.

**A.8.3.3.6** Some window assemblies have been tested to meet the conditions of acceptance of ASTM E 119, *Standard Test Methods for Fire Tests of Building Construction and Materials*, or ANSI/UL 263, *Standard for Fire Tests of Building Construction and Materials*. Where such assemblies are used, the provisions of 8.3.2 should be applied instead of those of 8.3.3.6.

**8.3.3.7** Fire resistance–rated glazing complying with 8.3.2.1.1 shall be permitted in fire doors and fire window assemblies in accordance with their listings.

**8.3.3.8** Glazing materials that have been tested, listed, and labeled to indicate the type of opening to be protected for fire protection purposes shall be permitted to be used in approved opening protectives in accordance with Table 8.3.4.2 and in sizes

in accordance with NFPA 80, *Standard for Fire Doors and Other Opening Protectives*.

**8.3.3.9** Existing installations of wired glass of ¼ in. (6.3 mm) thickness and labeled for fire protection purposes shall be permitted to be used in approved opening protectives, provided that the maximum size specified by the listing is not exceeded.

**8.3.3.10** Nonsymmetrical fire protection–rated glazing systems shall be tested with each face exposed to the furnace, and the assigned fire protection rating shall be that of the shortest duration obtained from the two tests conducted in compliance with NFPA 257, *Standard on Fire Test for Window and Glass Block Assemblies*, or ANSI/UL 9, *Standard for Fire Tests of Window Assemblies*.

**8.3.3.11** The total combined area of glazing in fire-rated window assemblies and fire-rated door assemblies used in fire barriers shall not exceed 25 percent of the area of the fire barrier that is common with any room, unless the installation meets one of the following criteria:

- (1) The installation is an existing fire window installation of wired glass and other fire-rated glazing materials in approved frames.
- (2) The fire protection–rated glazing material is installed in approved existing frames.

**8.3.3.12** New fire protection–rated glazing shall be marked in accordance with Table 8.3.3.12 and Table 8.3.4.2, and such marking shall be permanently affixed.

**Table 8.3.3.12 Marking Fire-Rated Glazing Assemblies**

Fire Test Standard	Marking	Definition of Marking
ASTM E119, or ANSI/UL 263 <sup>a</sup>	W	Meets wall assembly criteria
NFPA 257	OH	Meets fire window assembly criteria, including the hose stream test
NFPA 252	D	Meets fire door assembly criteria
	H	Meets fire door assembly hose stream test
	T	Meets 450° F (232°C) temperature rise criteria for 30 minutes
	XXX	The time, in minutes, of fire resistance or fire protection rating of the glazing assembly

<sup>a</sup>ASTM E 119, *Standard Test Methods for Fire Tests of Building Construction and Materials* and ANSI/UL 263, *Standard for Fire Tests of Building Construction and Materials*.

The requirements of 8.3.3.5 through 8.3.3.12 provide specifications for fire window assemblies that parallel those covered by 8.3.3.1 through 8.3.3.4 for fire door assemblies. New glazing for use in fire barriers and fire doors is regulated by performance-oriented criteria, which refer to fire-rated glazing, in lieu of the more traditional but prescriptive requirements previously applicable to wired glass. The requirements limit the installation of fire windows used in fire barriers to not more than 25 percent of the area of the fire barrier that is common with any room; however, 8.3.3.11 continues to recognize the current practice of using greater percentages of wired glass for existing fire windows.

The marking requirements for fire protection-rated glazing in 8.3.3.12 and Table 8.3.3.12 vary, depending on whether the glazing is installed in a door or a wall, and provide details on the test criteria at a glance. The prescribed marking scheme is consistent with the requirements of NFPA 5000, *Building Construction and Safety Code*, and other model building codes.

**8.3.3.13** Fire-rated door assemblies shall be inspected and tested in accordance with NFPA 80, *Standard for Fire Doors and Other Opening Protectives*.

### 8.3.4 Opening Protectives.

**8.3.4.1** Every opening in a fire barrier shall be protected to limit the spread of fire and restrict the movement of smoke from one side of the fire barrier to the other.

**8.3.4.2\*** The fire protection rating for opening protectives in fire barriers, fire-rated smoke barriers, and fire-rated smoke partitions shall be in accordance with Table 8.3.4.2, except as otherwise permitted in 8.3.4.3 or 8.3.4.4.

**A.8.3.4.2** Longer ratings might be required where opening protectives are provided for property protection as well as life safety. NFPA 80, *Standard for Fire Doors and Other Opening Protectives*, should be consulted for standard practice in the selection and installation of fire door assemblies and fire window assemblies.

**Table 8.3.4.2.** A vision panel in a fire door is not a fire window, and, thus, it is not the intent of the “NP” notations in the “Fire Window Assemblies” column of Table 8.3.4.2 to prohibit vision panels in fire doors.

**8.3.4.2.1** Fire-rated glazing assemblies marked as complying with hose stream requirements (H) shall be permitted in applications that do not require compliance with hose stream requirements. Fire-rated glazing assemblies marked as complying with temperature rise requirements (T) shall be permitted in applications that do not require compliance with temperature rise requirements. Fire-rated glazing assemblies marked with ratings that exceed the ratings required by this *Code* (XXX) shall be permitted.

Table 8.3.4.2 does not mandate fire resistance ratings for the components listed; rather, it specifies the fire protection rating

needed for openings where the listed components are required to be rated by another section of the *Code*. For example, not all exit access corridors are required to be rated. However, where corridor walls are required by another section of the *Code* to have a 1-hour rating, the doors therein must have a ½-hour (or 20-minute) fire protection rating. The table also specifies the maximum sizes of fire-rated door vision panels and glazing markings for various applications; the minimum fire protection or fire resistance rating for doorway sidelights or transoms and glazing markings for various applications; and the minimum fire protection ratings for fire window assemblies and associated markings for various applications. Although Table 8.3.4.2 was revised for the 2015 edition, no technical changes were intended. The revisions were intended to clarify its application to fire-protection and fire-resistance rated glazing used in rated window assemblies.

**8.3.4.3** Existing fire door assemblies having a minimum ¾-hour fire protection rating shall be permitted to continue to be used in vertical openings and in exit enclosures in lieu of the minimum 1-hour fire protection rating required by Table 8.3.4.2.

**8.3.4.4** Where a 20-minute fire protection-rated door is required in existing buildings, an existing 1¾ in. (44 mm) solid-bonded wood-core door, an existing steel-clad (tin-clad) wood door, or an existing solid-core steel door with positive latch and closer shall be permitted, unless otherwise specified by Chapters 11 through 43.

Fire barriers have fire *resistance* ratings, as addressed in 8.3.1; opening protectives, such as fire doors, have fire *protection* ratings, as discussed in 8.3.3. For a better understanding of the difference in test methods used for rating fire barriers and fire doors, compare the commentary following 8.2.3.2 and 8.3.3.3.

In general, 1-hour fire barriers for the protection of vertical openings (e.g., the walls enclosing maximum three-story exit stairs) require doors with a 1-hour fire protection rating. One-hour fire barriers for other than vertical opening protection, such as those used to isolate a hazardous contents room, require doors with a ¾-hour fire protection rating.

In some cases, other sections of the *Code* modify the general rules stated in the previous paragraph. Table 8.3.4.2 permits a 1-hour or ½-hour fire resistance-rated corridor wall or 1-hour fire resistance-rated smoke barrier to have a door with a 20-minute fire protection rating. Health care and ambulatory health care occupancies permit the omission of the self-closing devices on patient room doors installed in corridor walls. This provision recognizes the functional needs for open doors in these facilities, and a true fire protection-rated patient room door assembly is not required.

The fire protection ratings of the opening protectives are sometimes permitted to be of a lower rating than the fire resistance rating of the fire barrier openings to be protected. For example, a 2-hour fire barrier is permitted to have its openings

protected by 1½-hour fire protection-rated door assemblies. The perceived mismatch of ratings actually accomplishes a reasonable, practical match — as explained in the paragraphs that follow.

The test procedures on which the ratings are based, that is, ASTM E 119 and ANSI/UL 263 for fire barriers and NFPA 252, ANSI/UL 10B, and ANSI/UL 10C (see commentary following 8.3.3.3) for fire doors, are different.

Although combustibles placed against a fire resistance-rated wall expose the wall to a considerable fire challenge, a fire protection-rated door assembly does not usually have combustibles placed against it, because the opening must be clear to use the door. Such a scenario suggests that, if a door — for example, a second door to a storage room that is no longer needed — is not to be used and combustible storage is to be placed at the door opening, the door should be removed and the opening replaced with solid construction to restore the wall to its required fire resistance rating.

**8.3.5 Penetrations.** The provisions of 8.3.5 shall govern the materials and methods of construction used to protect through-penetrations and membrane penetrations in fire walls, fire barrier walls, and fire resistance-rated horizontal assemblies. The provisions of 8.3.5 shall not apply to approved existing materials and methods of construction used to protect existing through-penetrations and existing membrane penetrations in fire walls, fire barrier walls, or fire resistance-rated horizontal assemblies, unless otherwise required by Chapters 11 through 43.

**8.3.5.1\* Firestop Systems and Devices Required.** Penetrations for cables, cable trays, conduits, pipes, tubes, combustion vents and exhaust vents, wires, and similar items to accommodate electrical, mechanical, plumbing, and communications systems that pass through a wall, floor, or floor/ceiling assembly constructed as a fire barrier shall be protected by a firestop system or device. The firestop system or device shall be tested in accordance with ASTM E 814, *Standard Test Method for Fire Tests of Through Penetration Fire Stops*, or ANSI/UL 1479, *Standard for Fire Tests of Through-Penetration Firestops*, at a minimum positive pressure differential of 0.01 in. water column (2.5 N/m<sup>2</sup>) between the exposed and the unexposed surface of the test assembly.

**A.8.3.5.1** Firestop materials become systems when installed to the listed firestop system design from an accredited testing laboratory. Installation of firestop materials to the listed system should meet all limitations of the system.

There are management system-based contractor approval or qualification programs offered by third-party, independent companies that quantifiably qualify a company to install firestop materials that become systems after proper installation. In each program, there is an industry firestop exam that gives the company a basis to appoint a “Designated Responsible Individual.”

Then, the third-party firm audits the firestop company’s product and systems documentation records in conjunction with

the company’s management system operational policies and procedures to verify company compliance. An audit also takes place on a project site to verify that the management system is working.

Where the configuration of a penetrating item or group of items is such that a listed system is determined to be nonexistent and reconfiguration of the penetrations or fire resistance-rated assembly is determined to be impractical or impossible, alternative methods for maintaining the integrity of the required fire resistance rating of the assembly should be permitted to be established using an engineering analysis based on a comparison of listed systems prepared by a manufacturer’s technical representative of the systems specified, by the laboratory that conducted the original test, or by a professional engineer.

ASTM E 2174, *Standard Practice for On-Site Inspection of Installed Fire Stops*, provides guidance for the inspection of through-penetration firestop systems tested in accordance with ASTM E 814, *Standard Test Method for Fire Tests of Through-Penetration Fire Stops*, and ANSI/UL 1479, *Standard for Fire Tests of Through-Penetration Firestops*.

Independent inspection paid for by the owner is in many specifications and referenced in this appendix using ASTM E 2174 and ASTM E 2393, *Standard Practice for On-Site Inspection of Installed Fire Resistive Joint Systems and Perimeter Fire Barriers*. As a result, there is an accreditation program available for firestop special inspection agencies.

One source of information on tested materials, devices, and systems for protecting through-penetrations of fire resistance-rated barriers is Volume 2 of the *UL Fire Resistance Directory*, published by Underwriters Laboratories.<sup>27</sup> Such devices and systems are designed to resist the spread of fire through openings in fire resistance-rated floor or wall barriers that accommodate penetrating items, such as electrical cables, cable trays, conduits, and pipes. Underwriters Laboratories classifies such devices and systems with respect to installation in a wall only, installation in a floor only, or installation in a wall or floor. The basic standard used by UL to investigate products in this category is ANSI/UL 1479, *Standard for Fire Tests of Through-Penetration Firestops*,<sup>28</sup> which is similar to ASTM E 814, *Standard Test Method for Fire Tests of Through-Penetration Fire Stops*.<sup>29</sup> A sampling of the currently classified devices includes the use of the following:

1. Ceramic fibers
2. Foamed silicones
3. Mineral wool batts
4. Intumescent sheets
5. Sealing blankets and plugs
6. Fittings and couplings
7. Various caulks, putties, and mastics
8. Spring-loaded guillotine blades

Over the life of a building, it is important to maintain the integrity of barriers to protect against fire penetration. Renovations or

Smoke barriers <sup>f,g</sup>	1	1/2	Maximum size tested	D-20 or D-W-20	3/4	3/4	D-H-45	D-H-W-20	3/4	3/4	OH-45	W-60
	1/2	1/2	Maximum size tested	D-20 or D-W-20	1/2	1/2	D-H-20	D-H-W-20	1/2	1/2	OH-20	W-30

For SI units, 1 in.<sup>2</sup> = 0.00064516 m<sup>2</sup>.

NP: Not permitted.

<sup>a</sup>Fire resistance-rated glazing tested to ASTM E 119, *Standard Test Methods for Fire Tests of Building Construction and Materials*; or ANSI/UL 263, *Standard for Fire Tests of Building Construction and Materials*, shall be permitted in the maximum size tested (see 8.3.3.7).

<sup>b</sup>Fire-rated glazing in exterior windows shall be marked in accordance with Table 8.3.3.12.

<sup>c</sup>See ASME A17.1, *Safety Code for Elevators and Escalators*, for additional information.

<sup>d</sup>See ASME A17.3, *Safety Code for Existing Elevators and Escalators*, for additional information.

<sup>e</sup>Maximum area of individual exposed lights shall be 1296 in.<sup>2</sup> (0.84 m<sup>2</sup>), with no dimension exceeding 54 in. (1.37 m) unless otherwise tested. [80: Table 4.4.5 Note b and 80:4.4.5.1].

<sup>f</sup>Fire doors are not required to have a hose stream test per ANSI/UL 10B, *Standard for Fire Tests of Door Assemblies*; or ANSI/UL 10C, *Standard for Positive Pressure Fire Tests of Door Assemblies*.

<sup>g</sup>For residential board and care, see 32.2.3.1 and 33.2.3.1.

Exhibit 8.6

Typical penetrations of a fire barrier.

any changes to building utilities will tend to violate the compartmentation provided when a building is first occupied.

Exhibit 8.6 illustrates some of the typical fire barrier penetrations, which are addressed by 8.3.5.

**8.3.5.1.1** The requirements of 8.3.5.1 shall not apply where otherwise permitted by any one of the following:

- (1) Where penetrations are tested and installed as part of an assembly tested and rated in accordance with ASTM E 119, *Standard Test Methods for Fire Tests of Building Construction and Materials*, or ANSI/UL 263, *Standard for Fire Tests of Building Construction and Materials*
- (2) Where penetrations through floors are enclosed in a shaft enclosure designed as a fire barrier
- (3) Where concrete, grout, or mortar has been used to fill the annular spaces around cast-iron, copper, or steel piping that penetrates one or more concrete or masonry fire resistance-rated assemblies and both of the following criteria are also met:
  - (a) The nominal diameter of each penetrating item shall not exceed 6 in. (150 mm), and the opening size shall not exceed 1 ft<sup>2</sup> (0.09 m<sup>2</sup>).
  - (b) The thickness of the concrete, grout, or mortar shall be the full thickness of the assembly.
- (4) Where firestopping materials are used with the following penetrating items, the penetration is limited to one floor, and the firestopping material is capable of preventing the passage of flame and hot gases sufficient to ignite cotton waste when subjected to the time-temperature fire conditions of ASTM E 119, *Standard Test Methods for Fire Tests of Building Construction and Materials*, or ANSI/UL 263, *Standard for Fire Tests of Building Construction and Materials* under a minimum positive pressure differential of 0.01 in. water column (2.5 Pa) at the location of the penetration for the time period equivalent to the required fire resistance rating of the assembly penetrated:

- (a) Steel, ferrous, or copper cables
- (b) Cable or wire with steel jackets
- (c) Cast-iron, steel, or copper pipes
- (d) Steel conduit or tubing

**8.3.5.1.2** The maximum nominal diameter of the penetrating item, as indicated in 8.3.5.1.1(4)(a) through (d), shall not be greater than 4 in. (100 mm) and shall not exceed an aggregate 100 in.<sup>2</sup> (64,520 mm<sup>2</sup>) opening in any 100 ft<sup>2</sup> (9.3 m<sup>2</sup>) of floor or wall area.

**8.3.5.1.3** Firestop systems and devices shall have a minimum 1-hour F rating, but not less than the required fire resistance rating of the fire barrier penetrated.

**8.3.5.1.4 T Ratings.** Penetrations in fire resistance-rated horizontal assemblies shall be required to have a T rating of at least 1 hour, but not less than the fire resistance rating of the horizontal assembly, and shall not be required for either of the following:

- (1) Floor penetrations contained within the cavity of a wall assembly.
- (2) Penetrations through floors or floor assemblies where the penetration is not in direct contact with combustible material.

**8.3.5.2 Sleeves.** Where the penetrating item uses a sleeve to penetrate the wall or floor, the sleeve shall be securely set in the wall or floor, and the space between the item and the sleeve shall be filled with a material that complies with 8.3.5.1.

**8.3.5.3 Insulation and Coverings.** Insulation and coverings for penetrating items shall not pass through the wall or floor unless the insulation or covering has been tested as part of the firestop system or device.

**8.3.5.4 Transmission of Vibrations.** Where designs take transmission of vibrations into consideration, any vibration isolation shall meet one of the following conditions:

- (1) It shall be provided on either side of the wall or floor.
- (2) It shall be designed for the specific purpose.

**8.3.5.5 Transitions.**

**8.3.5.5.1** Where piping penetrates a fire resistance-rated wall or floor assembly, combustible piping shall not connect to non-combustible piping within 36 in. (915 mm) of the firestop system or device without demonstration that the transition will not reduce the fire resistance rating, except in the case of previously approved installations.

**8.3.5.5.2** Unshielded couplings shall not be used to connect noncombustible piping to combustible piping unless it can be demonstrated that the transition complies with the fire-resistive requirements of 8.3.5.1.

**8.3.5.6 Membrane Penetrations.**

The term *membrane penetration* refers to openings for penetrations made through one side only of a fire resistance-rated assembly, as defined in NFPA 5000, *Building Construction and*

*Safety Code.* The provisions of 8.3.5.6 address such penetrations, which, if not properly protected, would compromise the fire-resistive integrity of the barrier. The term *through-penetration*, on the other hand, refers to openings for penetrations that pass through both sides of a fire barrier.

**8.3.5.6.1** Membrane penetrations for cables, cable trays, conduits, pipes, tubes, combustion vents and exhaust vents, wires, and similar items to accommodate electrical, mechanical, plumbing, and communications systems that pass through a membrane of a wall, floor, or floor/ceiling assembly constructed as a fire barrier shall be protected by a firestop system or device and shall comply with 8.3.5.1 through 8.3.5.2.

**8.3.5.6.2** The firestop system or device shall be tested in accordance with ASTM E 814, *Standard Test Method for Fire Tests of Through Penetration Fire Stops*, or ANSI/UL 1479, *Standard for Fire Tests of Through-Penetration Firestops*, at a minimum positive pressure differential of 0.01 in. water column (2.5 N/m<sup>2</sup>) between the exposed and the unexposed surface of the test assembly, unless one of the following applies:

- (1) Membrane penetrations of ceilings that are not an integral part of a fire resistance-rated floor/ceiling or roof/ceiling assembly shall be permitted.
- (2) Membrane penetrations of steel, ferrous, or copper conduits, and pipes, tubes, or combustion vents or exhaust vents, shall be permitted where the annular space is protected with an approved material and the aggregate area of the openings does not exceed 0.7 ft<sup>2</sup> (0.06 m<sup>2</sup>) in any 100 ft<sup>2</sup> (9.3 m<sup>2</sup>) of ceiling area.
- (3) Electrical outlet boxes and fittings shall be permitted, provided that such devices are listed for use in fire resistance-rated assemblies and are installed in accordance with their listing.
- (4) The annular space created by the membrane penetration of a fire sprinkler shall be permitted, provided that the space is covered by a metal escutcheon plate.

**8.3.5.6.3** Where walls or partitions are required to have a minimum 1-hour fire resistance rating, recessed fixtures shall be installed in the wall or partition in such a manner that the required fire resistance is not reduced, unless one of the following is met:

- (1) Any steel electrical box not exceeding 0.1 ft<sup>2</sup> (0.01 m<sup>2</sup>) shall be permitted where the aggregate area of the openings provided for the boxes does not exceed 0.7 ft<sup>2</sup> (0.06 m<sup>2</sup>) in any 100 ft<sup>2</sup> (9.3 m<sup>2</sup>) of wall area, and, where outlet boxes are installed on opposite sides of the wall, the boxes shall be separated by one of the following:
  - (a) Horizontal distance of not less than 24 in. (610 mm)
  - (b) Horizontal distance of not less than the depth of the wall cavity, where the wall cavity is filled with cellulose loose-fill, rock wool, or slag wool insulation
  - (c)\* Solid fireblocking
  - (d) Other listed materials and methods

- (2) Membrane penetrations for any listed electrical outlet box made of any material shall be permitted, provided that such boxes have been tested for use in fire resistance-rated assemblies and are installed in accordance with the instructions included in the listing.
- (3) The annular space created by the membrane penetration of a fire sprinkler shall be permitted, provided that the space is covered by a metal escutcheon plate.
- (4) Membrane penetrations by electrical boxes of any size or type, which have been listed as part of a wall opening protective material system for use in fire resistance-rated assemblies and are installed in accordance with the instructions included in the listing, shall be permitted.

**A.8.3.5.6.3(1)(c)** Criteria associated with fireblocking can be found in 8.14.2 of *NFPA 5000, Building Construction and Safety Code*.

**8.3.5.7 Openings for Air-Handling Ductwork.** Openings in fire barriers for air-handling ductwork or air movement shall be protected in accordance with 9.2.1.

In referencing 9.2.1 for the protection of openings in fire barriers for air-handling ductwork or air movement, 8.3.5.7 mandates that the requirements of NFPA 90A, *Standard for the Installation of Air-Conditioning and Ventilating Systems*,<sup>30</sup> and not the usual *Life Safety Code* requirements for opening protectives (contained in 8.3.4), apply to heating, ventilating, and air-conditioning (HVAC) system penetrations of fire barriers. NFPA 90A requires that approved fire dampers be provided in all air-transfer openings in barriers that are required to have a fire resistance rating. It also requires that approved fire dampers be provided where ducts penetrate barriers that are required to have a fire resistance rating of 2 hours or more. Thus, although any air-transfer opening would have to be provided with a fire damper in a required fire barrier of any rating, penetrations by ducts would not have to be provided with fire dampers if the required rating of the fire barrier were less than 2 hours. These requirements are depicted in Exhibit 8.7.

*Fire damper requirements of NFPA 90A for HVAC penetrations of fire barriers.*

### 8.3.6 Joints.

**8.3.6.1** The provisions of 8.3.6 shall govern the materials and methods of construction used to protect joints in between and at the perimeter of fire barriers or, where fire barriers meet other fire barriers, the floor or roof deck above, or the outside walls. The provisions of 8.3.6 shall not apply to approved existing materials and methods of construction used to protect existing joints in fire barriers, unless otherwise required by Chapters 11 through 43.

**8.3.6.2** Joints made within or at the perimeter of fire barriers shall be protected with a joint system that is capable of limiting the transfer of smoke.

**8.3.6.3** Joints made within or between fire barriers shall be protected with a smoke-tight joint system that is capable of limiting the transfer of smoke.

**8.3.6.4** Testing of the joint system in a fire barrier shall be representative of the actual installation suitable for the required engineering demand without compromising the fire resistance rating of the assembly or the structural integrity of the assembly.

**8.3.6.5\*** Joints made within or between fire resistance-rated assemblies shall be protected with a joint system that is designed and tested to prevent the spread of fire for a time period equal to that of the assembly in which the joint is located. Such materials, systems, or devices shall be tested as part of the assembly in accordance with the requirements of ASTM E 1966, *Standard Test Method for Fire-Resistive Joint Systems*, or ANSI/UL 2079, *Standard for Tests for Fire Resistance of Building Joint Systems*.

**A.8.3.6.5** Materials used to protect joints become systems when installed to the listed joint system design from an accredited testing laboratory. Installation of joint materials to the listed system should meet all limitations of the system.

There are management system-based contractor approval or qualification programs offered by third-party, independent companies that quantifiably qualify a company to install fire-stop materials that become systems after proper installation. In each program, there is an industry firestop exam that gives the company a basis to appoint a “Designated Responsible Individual.”

Then, the third-party firm audits the firestop company’s product and systems documentation records in conjunction with the company’s management system operational policies and procedures to verify company compliance. An audit also takes place on a project site to verify that the management system is working.

Where the configuration of a joint is such that a listed system is determined to be nonexistent and reconfiguration of the joint or fire resistance-rated assembly is determined to be impractical or impossible, alternative methods for maintaining the integrity

of the required fire resistance rating of the assembly should be permitted to be established using an engineering analysis based on a comparison of listed systems prepared by a manufacturer’s technical representative of the systems specified, by the laboratory that conducted the original test, or by a professional engineer.

On-site inspection of firestopping is important in maintaining the integrity of any vertical or horizontal fire barrier. Two standard practice documents were developed with the ASTM process to allow inspections of through-penetration firestops, joints, and perimeter fire barrier systems. ASTM E 2393, *Standard Practice for On-Site Inspection of Installed Fire Resistive Joint Systems and Perimeter Fire Barriers*, provides guidance for the inspection of fire-resistive joints and perimeter fire barrier joint systems tested in accordance with the requirements of ASTM E 1966, *Standard Test Method for Fire-Resistive Joint Systems*, or with ANSI/UL 2079, *Standard for Tests for Fire Resistance of Building Joint Systems*. ASTM E 2393 contains a standardized report format, which would lead to greater consistency for inspections.

Independent inspection paid for by the owner is in many specifications and referenced in this appendix using ASTM E 2393. As a result, there is an accreditation program available for firestop special inspection agencies.

**8.3.6.6** All joint systems shall be tested at their maximum joint width in accordance with the requirements of ASTM E 1966, *Standard Test Method for Fire-Resistive Joint Systems*, or ANSI/UL 2079, *Standard for Tests for Fire Resistance of Building Joint Systems*, under a minimum positive pressure differential of 0.01 in. water column (2.5 N/m<sup>2</sup>) for a time period equal to that of the assembly. All test specimens shall comply with the minimum height or length required by the standard. Wall assemblies shall be subjected to a hose stream test in accordance with ASTM E 119, *Standard Test Methods for Fire Tests of Building Construction and Materials*, or ANSI/UL 263, *Standard for Fire Tests of Building Construction and Materials*.

#### 8.3.6.7\* Exterior Curtain Walls and Perimeter Joints.

**A.8.3.6.7** The provisions of 8.3.6.7 are intended to restrict the interior vertical passage of flame and hot gases from one floor to another at the location where the floor intersects the exterior wall assembly. The requirements of 8.3.6.7 mandate sealing the opening between a floor and an exterior wall assembly to provide the same fire performance as that required for the floor. ASTM E 2307, *Standard Test Method for Determining Fire Resistance of Perimeter Fire Barrier Systems Using Intermediate-Scale, Multi-Story Test Apparatus*, is a test method for evaluating the performance of perimeter fire barrier systems. Some laboratories have tested and listed perimeter fire barrier systems essentially in accordance with the ASTM method. The ASTM test method evaluates the performance of perimeter fire barrier systems in terms of heat transfer and fire spread inside a building through

the floor/interior wall intersection. The current test method does not assess the ability of perimeter fire barrier systems to prevent the spread of fire from story to story via the exterior. However, some laboratories have included additional temperature measurement criteria in their evaluation of the exterior wall, and also evaluate vision glass breakage, as additional pass/fail criteria in an attempt to at least partially address this leapfrog effect.

**8.3.6.7.1** Voids created between the fire resistance-rated floor assembly and the exterior curtain wall shall be protected with a perimeter joint system that is designed and tested in accordance with ASTM E 2307, *Standard Test Method for Fire Resistance of Perimeter Fire Barriers Using Intermediate-Scale, Multi-story Apparatus*.

**8.3.6.7.2** The perimeter joint system shall have an F rating equal to the fire resistance rating of the floor assembly.

It is important that joints between and within fire barriers be protected by materials tested to ensure the integrity of the barrier. Like a weak link in a chain, an improperly protected joint in a fire barrier is likely to be the point of failure when exposed to fire.

## 8.4 Smoke Partitions

The concept of the smoke partition is intended to serve as another menu-like item that can be referenced by other parts of the *Code*, typically the occupancy chapters, instead of repeating detailed criteria in many chapters. For an example of a mandate for the use of the smoke partition provisions of [Section 8.4](#) in large residential board and care occupancies, see [32.3.3.6.3](#) and [33.3.3.6.3.2](#).

The smoke partition provisions offer options not available prior to the 2000 edition of the *Code* under the provisions for fire barriers and smoke barriers. For example, a smoke partition is not always required to have a fire resistance rating, but all fire barriers must have a rating. Also, a smoke partition is not required to have a smoke damper where ductwork penetrates the partition, but a duct penetration of a smoke barrier typically is required to do so.

**8.4.1\* General.** Where required elsewhere in this *Code*, smoke partitions shall be provided to limit the transfer of smoke.

**A.8.4.1** Although a smoke partition is intended to limit the free movement of smoke, it is not intended to provide an area that would be free of smoke.

**Chapter 8** does not require the installation of smoke partitions but provides detailed criteria for smoke partitions where required by other sections of the *Code*. A smoke partition is a continuous membrane designed to form a barrier to limit the transfer of smoke.

**8.4.2 Continuity.** Smoke partitions shall comply with the following:

- (1) They shall extend from the floor to the underside of the floor or roof deck above, through any concealed spaces, such as those above suspended ceilings, and through interstitial structural and mechanical spaces.
- (2)\* They shall be permitted to extend from the floor to the underside of a monolithic or suspended ceiling system where all of the following conditions are met:
  - (a) The ceiling system forms a continuous membrane.
  - (b) A smoke-tight joint is provided between the top of the smoke partition and the bottom of the suspended ceiling.
  - (c) The space above the ceiling is not used as a plenum.
- (3) Smoke partitions enclosing hazardous areas shall be permitted to terminate at the underside of a monolithic or suspended ceiling system where all of the following conditions are met:
  - (a) The ceiling system forms a continuous membrane.
  - (b) A smoke-tight joint is provided between the top of the smoke partition and the bottom of the suspended ceiling.
  - (c) Where the space above the ceiling is used as a plenum, return grilles from the hazardous area into the plenums are not permitted.

**A.8.4.2(2)** An architectural, exposed, suspended-grid acoustical tile ceiling with penetrations for sprinklers, ducted HVAC supply and return-air diffusers, speakers, and recessed light fixtures is capable of limiting the transfer of smoke.

A smoke partition should be thought of as a barrier that reasonably limits, but does not necessarily prevent, smoke transfer. As such, there are suspended ceiling systems and monolithic surfaced ceilings that provide resistance to smoke transfer that is approximately equal to that of the traditional, nonrated corridor wall or partition. Smoke partitions are permitted to terminate tightly against the underside of such ceilings in accordance with [8.4.2\(2\)](#). The concept is further described in [A.8.4.2\(2\)](#). The list of acceptable penetrating items (e.g., speakers, recessed light fixtures, and ducted HVAC air diffusers) makes it clear that a smoke partition is not intended to prevent all smoke transfer; rather, it limits the transfer of smoke to an acceptable level to provide for occupant life safety.

### 8.4.3 Opening Protectives.

**8.4.3.1** Doors in smoke partitions shall comply with [8.4.3.2](#) through [8.4.3.5](#).

**8.4.3.2** Doors shall comply with the provisions of [7.2.1](#).

**8.4.3.3** Doors shall not include louvers.

**8.4.3.4\*** Door clearances shall be in accordance with NFPA 80, *Standard for Fire Doors and Other Opening Protectives*.

**A.8.4.3.4** Gasketing of doors should not be necessary, as the clearances in NFPA 80, *Standard for Fire Doors and Other Opening Protectives*, effectively achieve resistance to the passage of smoke if the door is relatively tight-fitting.

For swinging doors with builder's hardware, NFPA 80, *Standard for Fire Doors and Other Opening Protectives*, permits clearances of not more than  $\frac{1}{8}$  in. (3.2 mm) [ $\pm\frac{1}{16}$  in. ( $\pm 1.6$  mm) for steel doors] between the top and vertical edges of the door and the frame, and the meeting edges of doors in swinging pairs. The clearance under the bottom of a fire door is permitted to be not more than  $\frac{3}{4}$  in. (19 mm).

With the permitted clearances, some smoke will pass to the opposite side of a closed door. It is important to remember that the intent of the smoke partition is not to prevent all smoke transfer but, rather, to limit the transfer of smoke to an acceptable level.

**8.4.3.5** Doors shall be self-closing or automatic-closing in accordance with 7.2.1.8.

The four provisions applicable to doors in smoke partitions are individually addressed in 8.4.3.2 through 8.4.3.5 to allow each to be singled out in the references made by other sections of the Code that require smoke partitions. For example, 33.3.3.6.3.2 exempts existing large residential board and care occupancies in sprinklered buildings from the self-closing requirement of 8.4.3.5 but retains the other door provisions.

**8.4.4 Penetrations.** The provisions of 8.4.4 shall govern the materials and methods of construction used to protect through-penetrations and membrane penetrations of smoke partitions.

**8.4.4.1** Penetrations for cables, cable trays, conduits, pipes, tubes, vents, wires, and similar items to accommodate electrical, mechanical, plumbing, and communications systems that pass through a smoke partition shall be protected by a system or material that is capable of limiting the transfer of smoke.

**8.4.4.2** Where designs take transmission of vibrations into consideration, any vibration isolation shall meet one of the following conditions:

- (1) It shall be provided on either side of the smoke partition.
- (2) It shall be designed for the specific purpose.

### 8.4.5 Joints.

**8.4.5.1** The provisions of 8.4.5 shall govern the materials and methods of construction used to protect joints in between and at the perimeter of smoke partitions or, where smoke partitions meet other smoke partitions, the floor or roof deck above, or the outside walls. The provisions of 8.4.5 shall not apply to approved existing materials and methods of construction used to protect existing joints in smoke partitions, unless otherwise required by Chapters 11 through 43.

**8.4.5.2** Joints made within or at the perimeter of smoke partitions shall be protected with a joint system that is capable of limiting the transfer of smoke.

### 8.4.6 Air-Transfer Openings.

**8.4.6.1 General.** The provisions of 8.4.6 shall govern the materials and methods of construction used to protect air-transfer openings in smoke partitions.

**8.4.6.2\* Smoke Dampers.** Air-transfer openings in smoke partitions shall be provided with approved smoke dampers designed and tested in accordance with the requirements of ANSI/UL 555S, *Standard for Smoke Dampers*, to limit the transfer of smoke.

**A.8.4.6.2** An air-transfer opening, as defined in NFPA 90A, *Standard for the Installation of Air-Conditioning and Ventilating Systems*, is an opening designed to allow the movement of environmental air between two contiguous spaces.

**8.4.6.3 Smoke Damper Ratings.** Smoke damper leakage ratings shall be not less than Class II. Elevated temperature ratings shall be not less than 250°F (140°C).

**8.4.6.4 Smoke Detectors.** Dampers in air-transfer openings shall close upon detection of smoke by approved smoke detectors installed in accordance with NFPA 72, *National Fire Alarm and Signaling Code*.

Where ductwork extends to a smoke partition, pierces the partition, and continues its run on the other side of the partition, no transfer opening exists. Given that no transfer opening is present, there is no requirement for a smoke damper. If such ducted HVAC systems without dampers are to spread smoke, such smoke spread will occur due to the buoyant forces of the hot fire gases, because the provisions of NFPA 90A, *Standard for the Installation of Air-Conditioning and Ventilating Systems*, require the automatic shutdown of most of the fans that would otherwise circulate smoke through the ductwork.

---

## 8.5 Smoke Barriers

**8.5.1\* General.** Where required by Chapters 11 through 43, smoke barriers shall be provided to subdivide building spaces for the purpose of restricting the movement of smoke.

**A.8.5.1** Wherever smoke barriers and doors therein require a degree of fire resistance, as specified by requirements in the various occupancy chapters (Chapters 12 through 42), the construction should be a fire barrier that has been specified to limit the spread of fire and restrict the movement of smoke.

Although a smoke barrier is intended to restrict the movement of smoke, it might not result in tenability throughout the adjacent smoke compartment. The adjacent smoke compartment

should be safer than the area on the fire side, thus allowing building occupants to move to that area. Eventually, evacuation from the adjacent smoke compartment might be required.

It is imprecise to refer to a “1-hour smoke barrier,” because smoke barriers are not classified based on the duration for which they resist the transfer of smoke. It is more accurate to refer to a “smoke barrier that additionally has a 1-hour fire resistance rating.” A barrier with only a fire resistance rating does not necessarily make an effective smoke barrier. For example, a fire barrier, if rated at less than 2 hours, would not be required to have either a fire damper or a smoke damper where ductwork penetrates the barrier. A smoke barrier, in accordance with Section 8.5, would generally have ducted penetrations protected by smoke dampers per 8.5.5.2. For additional information on fire barrier testing, rating, and installation, see the commentary following 8.2.3.2 and 8.3.5.7.

### 8.5.2\* Continuity.

**A.8.5.2** To ensure that a smoke barrier is continuous, it is necessary to seal completely all openings where the smoke barrier abuts other smoke barriers, fire barriers, exterior walls, the floor below, and the floor or ceiling above. It is not the intent to prohibit a smoke barrier from stopping at a fire barrier if the fire barrier meets the requirements of a smoke barrier (i.e., the fire barrier is a combination smoke barrier/fire barrier).

**8.5.2.1** Smoke barriers required by this Code shall be continuous from an outside wall to an outside wall, from a floor to a floor, or from a smoke barrier to a smoke barrier, or by use of a combination thereof.

**8.5.2.2** Smoke barriers required by this Code shall be continuous through all concealed spaces, such as those found above a ceiling, including interstitial spaces.

**8.5.2.3** A smoke barrier required for an occupied space below an interstitial space shall not be required to extend through the interstitial space, provided that the construction assembly forming the bottom of the interstitial space provides resistance to the passage of smoke equal to that provided by the smoke barrier.

In occupancies where evacuation is a last resort or is expected to be otherwise delayed, smoke barriers and doors will require a degree of fire resistance, as specified by the requirements found in the Code’s occupancy chapters (Chapters 12 through 42).

Other openings in smoke and fire barriers must be protected as well. HVAC ducts provide a ready path for smoke and fire to travel from one area to another unless appropriately protected. Penetrations in walls and ceiling construction for utilities and other building services must be firestopped to prevent fire spread. The hidden spaces above suspended ceilings and attic spaces are out of sight and can be easily overlooked.

The provision of 8.5.2.3 must be used with care. Several occupancy chapters require smoke barriers to be fire resistance

rated and, therefore, the smoke barrier would be permitted to terminate at the ceiling only if the ceiling were of the same rating (see commentary following A.8.3.1.2). Also, even where no fire resistance rating is required, it is difficult to ensure that a ceiling is smoketight, unless it is of monolithic construction without air-handling penetrations. This kind of construction is often found in apartment buildings, hotels, and dormitories; consequently, the provision of 8.5.2.3 can be useful.

**8.5.3 Fire Barrier Used as Smoke Barrier.** A fire barrier shall be permitted to be used as a smoke barrier, provided that it meets the requirements of Section 8.5.

### 8.5.4 Opening Protectives.

**8.5.4.1\*** Doors in smoke barriers shall close the opening, leaving only the minimum clearance necessary for proper operation, and shall be without louvers or grilles. For other than previously approved existing doors, the clearance under the bottom of the doors shall be a maximum of ¾ in. (19 mm).

**A.8.5.4.1** For additional information on the installation of smoke control door assemblies, see NFPA 105, *Standard for Smoke Door Assemblies and Other Opening Protectives*.

NFPA 105, *Standard for Smoke Door Assemblies and Other Opening Protectives*,<sup>31</sup> acknowledges that no nationally recognized test standard for the measurement of hot smoke temperature leakage exists. However, NFPA 105 notes that ANSI/UL 1784, *Standard for Air Leakage Tests of Door Assemblies*,<sup>32</sup> can be used to measure ambient and warm air leakage rates of door assemblies.

ANSI/UL 1784, which is also referenced in 8.2.2.4, should determine satisfactory performance if recognized design features are also taken into account, such as close-fitting assemblies, limited deflections, and the use of gasketing and sealing materials. The document then provides performance criteria for determining maximum air leakage rates expressed in air volume per time per area of door opening.

**8.5.4.2** Where required by Chapters 11 through 43, doors in smoke barriers that are required to be smoke leakage-rated shall comply with the requirements of 8.2.2.4.

**8.5.4.3** Latching hardware shall be required on doors in smoke barriers, unless specifically exempted by Chapters 11 through 43.

**8.5.4.4\*** Doors in smoke barriers shall be self-closing or automatic-closing in accordance with 7.2.1.8 and shall comply with the provisions of 7.2.1.

**A.8.5.4.4** Where, because of operational necessity, it is desired to have smoke barrier doors that are usually open, such doors should be provided with hold-open devices that are activated to close the doors by means of the operation of smoke detectors and other alarm functions.

Doors in smoke barriers are not generally required to have a fire protection rating, unless the applicable occupancy chapter

requires the smoke barrier itself to have a fire resistance rating. Therefore, any door that resists the passage of smoke, even a hollow-core wood door or glass door, is acceptable, provided that it is tight-fitting, unless the door is required to be smoke leakage-rated as specified by 8.5.4.2. Stops at the head and sides of the door help resist the passage of smoke. Where a pair of doors is used, it is recommended (and required for cross-corridor door assemblies in new health care occupancies) that they open in opposite directions from each other so that rabbets, bevels, or astragals can be provided at the meeting edges without the use of coordinators. See 18.3.7.6 through 18.3.7.10 for details on smoke barrier doors in new health care occupancies.

Doors in smoke barriers, although not the equivalent of fire doors and not completely smoke tight, are effective in restricting the spread of smoke and reducing drafts, which might otherwise spread fire rapidly. Where an occupancy chapter requires the smoke barrier to have a fire resistance rating, a 20-minute fire protection-rated door assembly should provide a reasonable degree of protection. It has been shown through tests that the commonly used 1¾ in. (44 mm) thick solid-bonded wood-core door assembly can be expected to fail in fire tests in 22 minutes to 24 minutes, but it has performed well in actual fires when closed.<sup>33</sup> The maximum clearance under the bottom of new smoke barrier doors is limited to ¾ in. (19 mm) as indicated in 8.5.4.1; this limit is intended to be consistent with the clearance permitted by NFPA 80, *Standard for Fire Doors and Other Opening Protectives*, for fire doors.

Doors in a fire barrier, horizontal exit, or smoke barrier should be closed at all times to impede the spread of smoke and fire gases. Functionally, however, keeping the doors closed can decrease the operational efficiency of the occupancy. In a health care occupancy, for example, closed doors limit patient observation by staff. To accommodate such situations, it is practical to presume that the door will be kept open, even with the use of wood chocks or other makeshift devices. Where operational necessity dictates that smoke barrier doors normally are to be kept open, such doors should be provided with hold-open devices that release by the operation of smoke detectors (see Exhibit 8.8). See 7.2.1.8.2 for details on automatic-closing doors. Smoke detectors for door releasing service are not necessarily required to activate a building evacuation alarm — see 9.6.3.2.3 for details.

8.5.4.5 Fire window assemblies shall comply with 8.3.3.

## 8.5.5 Ducts and Air-Transfer Openings.

**8.5.5.1 General.** The provisions of 8.5.5 shall govern the materials and methods of construction used to protect ducts and air-transfer openings in smoke barriers.

### 8.5.5.2 Smoke Dampers.

**8.5.5.2.1** Where a smoke barrier is penetrated by a duct or air-transfer opening, a smoke damper designed and tested in accordance with the requirements of ANSI/UL 555S, *Standard for Smoke Dampers*, shall be installed.

Exhibit 8.8

Hold-open mechanism on automatic-closing door.

**8.5.5.2.2** Where a smoke barrier is also constructed as a fire barrier, a combination fire/smoke damper designed and tested in accordance with the requirements of ANSI/UL 555, *Standard for Fire Dampers*, and ANSI/UL 555S, *Standard for Smoke Dampers*, shall be installed.

**8.5.5.3 Smoke Damper Exemptions.** Smoke dampers shall not be required under any of the following conditions:

- (1) Where specifically exempted by provisions in Chapters 11 through 43
- (2) Where ducts or air-transfer openings are part of an engineered smoke control system and the smoke damper will interfere with the operation of a smoke control system
- (3) Where the air in ducts continues to move and the air handling system installed is arranged to prevent recirculation of exhaust or return air under fire emergency conditions

Paragraph 8.5.5.3(2) addresses the omission of dampers in ducts that must remain open so that an engineered smoke control system can operate. The provision of 8.5.5.3(3) applies only in very limited cases. It can be used only on small ventilation systems, because NFPA 90A, *Standard for the Installation of Air-Conditioning and Ventilating Systems*, requires that systems with an air-handling capacity over 15,000 ft<sup>3</sup>/min (7080 L/s) that are not part of a smoke control system shut down upon detection of smoke.

Even without the restriction of NFPA 90A, it is difficult to ensure that the air-handling system will be in continuous operation. Because of increased awareness of energy conservation, many systems are cycled or shut down during parts of the day. The cycling or shutdown feature might be added later without recognizing its potential detriment to occupant life safety. However, the provisions of 8.5.5.3(3) can be useful for ductwork for small ventilation systems, such as those for toilet rooms or small suites.

- (4) Where the air inlet or outlet openings in ducts are limited to a single smoke compartment

Paragraph 8.5.5.3(4) addresses situations where an “express” duct has no openings other than in a single smoke compartment. This provision can reasonably be extended to situations illustrated in Exhibit 8.9. Per the requirements of NFPA 90A, *Standard for the Installation of Air-Conditioning and Ventilating Systems*, only a single floor can be penetrated by ductwork not enclosed within a rated shaft, and such an installation requires a fire damper at the plane of the floor where the penetration is located. Ducts penetrating more than one floor must be enclosed within an appropriately fire-rated shaft. Thus, where a smoke damper is exempted by 8.5.5.3(5), the resulting openings can potentially act as a minor route for smoke migration from one

floor to another before the actuation of a fire damper. The floor, as a whole, serves as an adequate smoke barrier in accordance with the requirements of 8.6.1.

- (5) Where ducts penetrate floors that serve as smoke barriers  
(6) Where ducts penetrate smoke barriers forming a communicating space separation in accordance with 8.6.6(4)(a)

#### 8.5.5.4 Installation, Testing, and Maintenance.

**8.5.5.4.1** Air-conditioning, heating, ventilating ductwork, and related equipment, including smoke dampers and combination fire and smoke dampers, shall be installed in accordance with NFPA 90A, *Standard for the Installation of Air-Conditioning and Ventilating Systems*, NFPA 90B, *Standard for the Installation of Warm Air Heating and Air-Conditioning Systems*, NFPA 105, *Standard for Smoke Door Assemblies and Other Opening Protectives*, or NFPA 80, *Standard for Fire Doors and Other Opening Protectives*, as applicable.

**8.5.5.4.2** Smoke dampers and combination fire and smoke dampers required by this Code shall be inspected, tested, and maintained in accordance with NFPA 105, *Standard for Smoke Door Assemblies and Other Opening Protectives*.

**8.5.5.4.3** The equipment specified in 8.5.5.4.1 shall be installed in accordance with the requirements of 8.5.5, the manufacturer’s installation instructions, and the equipment listing.

#### 8.5.5.5 Access and Identification.

**8.5.5.5.1** Access to the dampers shall be provided for inspection, testing, and maintenance.

**8.5.5.5.2** Smoke and combination fire and smoke dampers in new construction shall be provided with an approved means of access, as follows:

- (1) The means of access shall be large enough to allow inspection and maintenance of the damper and its operating parts.
- (2) The access shall not affect the integrity of fire resistance-rated assemblies or smoke barrier continuity.
- (3) The access openings shall not reduce the fire resistance rating of the assembly.
- (4) Access doors in ducts shall be tight-fitting and suitable for the required duct construction.
- (5) Access and maintenance shall comply with the requirements of the mechanical code.

**8.5.5.5.3 Identification.** Access points to fire and smoke dampers in new construction shall be permanently identified by one of the following:

- (1) A label having letters not less than ½ in. (13 mm) in height and reading as one of the following:
  - (a) FIRE/SMOKE DAMPER
  - (b) SMOKE DAMPER
  - (c) FIRE DAMPER
- (2) Symbols as approved by the authority having jurisdiction

Position of smoke dampers in air-handling ductwork.

Requirements for access to, and identification of, fire dampers, smoke dampers, and combination fire and smoke dampers, were revised for the 2015 edition of the *Code* to be consistent with the requirements of *NFPA 5000, Building Construction and Safety Code*. In new construction, access locations must be labeled to facilitate the required inspection, testing, and maintenance of dampers.

**8.5.5.6 Smoke Damper Ratings.** Smoke damper leakage ratings shall be not less than Class II. Elevated temperature ratings shall be not less than 250°F (140°C).

#### 8.5.5.7 Smoke Detectors.

**8.5.5.7.1** Required smoke dampers in ducts penetrating smoke barriers shall close upon detection of smoke by approved smoke detectors in accordance with *NFPA 72, National Fire Alarm and Signaling Code*, unless one of the following conditions exists:

- (1) The ducts penetrate smoke barriers above the smoke barrier doors, and the door release detector actuates the damper.
- (2) Approved smoke detector installations are located within the ducts in existing installations.

**8.5.5.7.2** Where a duct is provided on one side of the smoke barrier, the smoke detectors on the duct side shall be in accordance with **8.5.5.7.1**.

**8.5.5.7.3** Required smoke dampers in air-transfer openings shall close upon detection of smoke by approved smoke detectors in accordance with *NFPA 72, National Fire Alarm and Signaling Code*.

*NFPA 72*<sup>9</sup>, *National Fire Alarm and Signaling Code*,<sup>34</sup> provides information on the installation of smoke detectors that close smoke dampers. The damper is permitted to be closed by the same detector that closes the door in a smoke barrier if the duct penetrates the wall above the door. Existing installations of detectors installed within ducts, which might not be in total compliance with *NFPA 72*, continue to be recognized.

#### 8.5.6 Penetrations.

**8.5.6.1** The provisions of **8.5.6** shall govern the materials and methods of construction used to protect through-penetrations and membrane penetrations of smoke barriers.

**8.5.6.2** Penetrations for cables, cable trays, conduits, pipes, tubes, vents, wires, and similar items to accommodate electrical, mechanical, plumbing, and communications systems that pass through a wall, floor, or floor/ceiling assembly constructed as a smoke barrier, or through the ceiling membrane of the roof/ceiling of a smoke barrier assembly, shall be protected by a system or material capable of restricting the transfer of smoke.

**8.5.6.3** Where a smoke barrier is also constructed as a fire barrier, the penetrations shall be protected in accordance with the requirements of **8.3.5** to limit the spread of fire for a time period equal to the fire resistance rating of the assembly and **8.5.6** to restrict the transfer of smoke, unless the requirements of **8.5.6.4** are met.

**8.5.6.4** Where sprinklers penetrate a single membrane of a fire resistance-rated assembly in buildings equipped throughout with an approved automatic fire sprinkler system, noncombustible escutcheon plates shall be permitted, provided that the space around each sprinkler penetration does not exceed ½ in. (13 mm), measured between the edge of the membrane and the sprinkler.

**8.5.6.5** Where the penetrating item uses a sleeve to penetrate the smoke barrier, the sleeve shall be securely set in the smoke barrier, and the space between the item and the sleeve shall be filled with a listed system or a material capable of restricting the transfer of smoke.

**8.5.6.6** Where designs take transmission of vibrations into consideration, any vibration isolation shall meet one of the following conditions:

- (1) It shall be provided on either side of the smoke barrier.
- (2) It shall be designed for the specific purpose.

#### 8.5.7 Joints.

**8.5.7.1** The provisions of **8.5.7** shall govern the materials and methods of construction used to protect joints in between and at the perimeter of smoke barriers or, where smoke barriers meet other smoke barriers, the floor or roof deck above, or the outside walls. The provisions of **8.5.7** shall not apply to approved existing materials and methods of construction used to protect existing joints in smoke barriers, unless otherwise required by **Chapters 11** through **43**.

**8.5.7.2** Joints made within or at the perimeter of smoke barriers shall be protected with a joint system that is capable of limiting the transfer of smoke.

**8.5.7.3** Joints made within or between smoke barriers shall be protected with a smoke-tight joint system that is capable of limiting the transfer of smoke.

**8.5.7.4** Smoke barriers that are also constructed as fire barriers shall be protected with a joint system that is designed and tested to resist the spread of fire for a time period equal to the required fire resistance rating of the assembly and restrict the transfer of smoke.

**8.5.7.5** Testing of the joint system in a smoke barrier that also serves as fire barrier shall be representative of the actual installation.

Exhibit 8.10

Typical penetrations of a smoke barrier.

As in the case of fire barriers, it is important to maintain the integrity of smoke barriers over the life of a building. Exhibit 8.10 illustrates some of the key items regarding smoke barrier penetrations discussed in 8.5.3 through 8.5.7.

## 8.6 Vertical Openings

Unprotected or improperly protected vertical openings have consistently been major contributing factors in multiple-death fires. This is particularly well illustrated by the two deadliest hotel fires in recent decades in the United States and its possessions.<sup>35</sup>

In 1986, 97 people died in a fire at the Dupont Plaza Hotel in San Juan, Puerto Rico. The unprotected vertical opening between the ballroom level, where the fire originated, and the casino level, where nearly all the deaths occurred, would not be permitted by the *Code*, given the lack of other fire protection design features of that area.<sup>36</sup>

In the 1980 MGM Grand Hotel fire in Las Vegas, Nevada, where 85 people died, smoke spread via unprotected vertical openings (concealed spaces, elevator shafts) and insufficiently protected exit stair enclosures.<sup>37</sup> Many factors contributed to the vertical smoke spread, including the following:

1. Unprotected seismic joints and elevator hoistways
2. Insufficiently fire resistance-rated construction used in interior stair enclosures
3. Exposure of exit stair and exit passageway spaces to casino level plenum air
4. Heating, ventilating, and air-conditioning systems with fire dampers that did not operate

Most of the hotel and motel fires of recent decades that have resulted in 10 or more fatalities have involved unprotected vertical openings, typically unenclosed interior stairs.

**8.6.1 Floor Smoke Barriers.** Every floor that separates stories in a building shall meet the following criteria:

- (1) It shall be constructed as a smoke barrier in accordance with Section 8.5.
- (2) It shall be permitted to have openings as described by 8.6.6, 8.6.7, 8.6.8, 8.6.9, or Chapters 11 through 43.

Prior to the 2006 edition of the *Code*, floors were required to provide a basic degree of smoke compartmentation, consistent with the definition of the term *smoke barrier* in 3.3.31.2, without meeting the detailed requirements of Section 8.5. In the 2006 edition, a reference to Section 8.5 in 8.6.1(1) was added to require all floors to meet the detailed requirements for true smoke barriers. Note that duct penetrations through a floor are exempt from the requirement for a smoke damper at the penetration by 8.5.5.3(5).

Paragraph 8.6.1(2) emphasizes that the communicating space, atrium, partially enclosed two-story opening, and convenience opening concepts addressed in 8.6.6, 8.6.7, 8.6.8, and 8.6.9, respectively, continue to be permitted, along with other unprotected vertical openings where permitted by the occupancy chapters. The use of such openings between floors should not be deemed to be in conflict with the requirements of Section 8.5 or 8.6.1(1).

**8.6.2\* Continuity.** Openings through floors shall be enclosed with fire barrier walls, shall be continuous from floor to floor, or floor to roof, and shall be protected as appropriate for the fire resistance rating of the barrier.

**A.8.6.2** Openings might include items such as stairways; hoistways for elevators, dumbwaiters, and inclined and vertical conveyors; shaftways used for light, ventilation, or building services; or expansion joints and seismic joints used to allow structural movements.

**8.6.3 Continuity Exemptions.** The requirements of 8.6.2 shall not apply where otherwise permitted by any of the following:

- (1) Where penetrations for cables, cable trays, conduits, pipes, tubes, combustion vents and exhaust vents, wires, pneumatic tube conveyors, and similar items to accommodate electrical, mechanical, plumbing, and communications systems are protected in accordance with 8.3.5.1 and 8.5.6
- (2) Where specified by 8.6.6, 8.6.7, 8.6.8, 8.6.9.1, 8.6.9.2, 8.6.9.3, or Chapters 11 through 43
- (3) Where escalators and moving walks are protected in accordance with 8.6.9.6 or 8.6.9.7

- (4) Where expansion or seismic joints are designed to prevent the penetration of fire and are shown to have a fire resistance rating of not less than that required for the floor when tested in accordance with ANSI/UL 2079, *Standard for Tests for Fire Resistance of Building Joint Systems*
- (5) Where existing mail chutes meet one of the following criteria:
- The cross-sectional area does not exceed 0.1 ft<sup>2</sup> (0.01 m<sup>2</sup>).
  - The building is protected throughout by an approved automatic sprinkler system in accordance with [Section 9.7](#).

It is important to note that [8.6.1](#) and [8.6.2](#) apply to all occupancies, unless a specific occupancy chapter provides an alternative option. Protection of vertical openings is normally covered in the [3.1](#) subsection of each occupancy chapter (e.g., [12.3.1](#) for new assembly occupancies or [18.3.1](#) for new health care occupancies).

Protection of vertical openings is extremely important in reducing fire casualties. In report after report of fires involving fatalities, unprotected vertical openings were a major factor contributing to loss of life.

Vertical fire spread is also a major factor contributing to the extensive property damage that is characteristic of large-loss building fires; thus, a correlation frequently exists between loss of life from fire and monetary loss from fire. Vertical fire spread relates directly to the lack of protection for vertical openings, because the principal structural weakness responsible for the vertical spread of fire is the absence of the fire cutoffs at openings between floors.

[Exhibit 8.11](#) illustrates some typical floor openings in buildings. If the exit stairs at each end of the building are not properly enclosed per the requirements of [7.1.3.2](#), they do not qualify as exits. If the exit stairs do not comply with the requirements of [Section 8.6](#) and the [3.1](#) subsection of the appropriate

*Typical floor openings that, if not properly enclosed, might spread the effects of a fire from floor to floor.*

occupancy chapter, they create unprotected vertical openings. The other floor openings illustrated in [Exhibit 8.11](#) are not affected by the requirements applicable to exits but do, if not properly enclosed, create unprotected vertical openings.

Based on lessons learned from the Las Vegas MGM Grand Hotel fire, the 1988 edition of the *Code* expanded the list of floor openings to include expansion joints and seismic joints that allow structural movement. In lieu of full enclosure from floor to floor, [8.6.3\(4\)](#) specifically recognizes the use of fire protection-rated expansion or seismic joints with a minimum rating of not less than the required fire resistance rating of the floor. Without appropriately rated joints, the enclosure requirements might be satisfied by an arrangement of walls and doors as shown in [Exhibit 8.12](#). Back-to-back fire resistance-rated barriers and cross-corridor fire protection-rated door assemblies accomplish the enclosure of the seismic joint running horizontally across the building and vertically through all floors.

*Enclosure of seismic joint.*

**8.6.4 Shafts.** Shafts that do not extend from the bottom to the top of the building or structure shall comply with [8.6.4.1](#), [8.6.4.2](#), or [8.6.4.3](#), as modified by [8.6.4.4](#) or [8.6.4.5](#).

**8.6.4.1** Shafts that do not extend to the top of the building or structure shall be enclosed at the highest level of the shaft with construction in accordance with [8.6.5](#).

**8.6.4.2** Shafts that do not extend to the bottom of the building or structure shall be enclosed at the lowest level of the shaft with construction in accordance with [8.6.5](#).

**8.6.4.3** Shafts that do not extend to the bottom and to the top of the building or structure shall be enclosed at the lowest and highest level of the shaft with construction in accordance with [8.6.5](#).

**8.6.4.4** In lieu of any enclosure required at lowest or highest level of a shaft by [8.6.4.1](#) through [8.6.4.3](#), shafts shall be permitted to terminate in a room or space having a use related to the purpose of the shaft, provided that the room or space is separated

from the remainder of the building by construction having a fire resistance rating and opening protectives in accordance with 8.6.5 and 8.3.4.

**8.6.4.5** Any enclosure required at the lowest or highest level of a shaft by 8.6.4.1 through 8.6.4.3 shall be permitted to be protected by approved fire dampers installed in accordance with their listing.

Some shafts commonly found in buildings do not extend through the entire height of the building. For example, in a high-rise building, a percentage of the overall number of elevator shafts will service only the low-rise portion of the building. Such shafts might run from the street level through the twentieth floor of a 40-story building. In a typical hotel that devotes the first couple of stories to assembly occupancy uses and locates guest rooms above in the hotel occupancy tower, the shafts associated with guest room bathroom exhaust might begin at the third floor and continue to the roof. In such cases, although the shaft walls are constructed of fire resistance-rated assemblies, an unprotected shaft ceiling/top or unprotected shaft floor/bottom would allow fire and other products of combustion to travel vertically to some other part of the building. Because of this concern, 8.6.4.1 through 8.6.4.3 require that those shaft ceilings, shaft floors, or both, be protected by fire resistance-rated construction as required for the shaft walls.

Exhibit 8.13 illustrates various shaft arrangements. Shafts that do not extend the full height of a building must be capped by floors or ceilings of fire resistance-rated construction at least equal to the required rating of the shaft-enclosing walls. Shaft A runs vertically for the full height of the building and requires only vertical fire barriers to separate the shaft from the

remainder of the building interior. Because neither shaft B nor shaft C extends the full height of the building, horizontal fire barriers (a floor for shaft B and a ceiling for shaft C) must be provided to complete the shaft envelope. Shaft D, which is used for heating, ventilating, and air-conditioning (HVAC), extends vertically from the second floor to the roof; 8.6.4.4 makes it unnecessary to provide a rated floor fire barrier between shaft D and the mechanical equipment room, E. In this case, the ceiling and walls of the mechanical equipment room, used for purposes related to the use of the HVAC shaft, must have at least the same hourly rating as required for shaft D. The room enclosure thus becomes an extension of the shaft. Access to room E from within the building would be gained through appropriately rated fire door assemblies.

**8.6.5\* Required Fire Resistance Rating.** The minimum fire resistance rating for the enclosure of floor openings shall be as follows (see 7.1.3.2.1 for enclosure of exits):

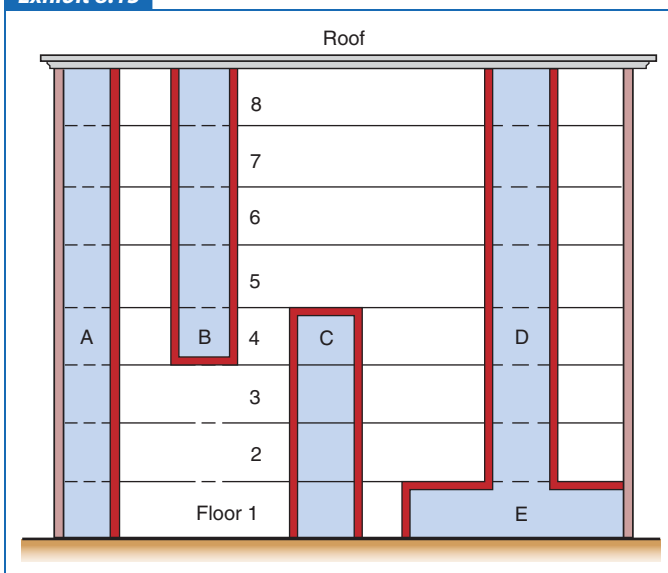

- (1) Enclosures connecting four or more stories in new construction — 2-hour fire barriers
- (2) Other enclosures in new construction — 1-hour fire barriers
- (3) Existing enclosures in existing buildings — ½-hour fire barriers
- (4) Enclosures for lodging and rooming houses — as specified in Chapter 26
- (5) Enclosures for new hotels — as specified in Chapter 28
- (6) Enclosures for new apartment buildings — as specified in Chapter 30

**A.8.6.5** The application of the 2-hour rule in buildings not divided into stories is permitted to be based on the number of levels of platforms or walkways served by the stairs.

Where addressing vertical openings, the Code does not use the height of buildings or a designated number of stories in height as the basis for its rated enclosure requirements. Rather, such requirements are based on the total number of stories connected by the vertical opening. For example, if there is a vertical opening between the second, third, and fourth stories of an eight-story building, the opening connects fewer than four floors, and the enclosure must have a fire resistance rating of 1 hour rather than 2 hours.

Where a vertical opening in new construction connects four stories or more, the enclosure must have at least a 2-hour fire resistance rating. This requirement applies whether the stories are above the exit discharge level, are below the exit discharge level, or are a combination thereof. Where a vertical opening in new construction connects three or fewer stories, the enclosure rating must be at least 1 hour. Existing vertical openings, regardless of the number of stories they connect, require protection by ½-hour fire resistance-rated enclosures. Note that exit enclosures are subject to the more stringent requirements of 7.1.3.2.

Exhibit 8.13

Shaft enclosures.

Exhibit 8.14

Vertical opening protection requirements.

Exhibit 8.14 illustrates the vertical opening protection requirements for new construction. Although Exhibit 8.14 depicts vertical openings that resemble exit stair enclosures, the same requirements apply to any type of vertical opening, including exit access stairs and elevator, electrical, HVAC, and seismic shafts.

Experience shows that, under some circumstances, each of the 1-hour and 2-hour rating levels provides a comfortable period of time for the occupants of a building to evacuate. On the other hand, there are times when the integrity of the construction will be taxed to its limit (e.g., during a fire that has gone undetected for a long period). This type of fire can generate heavy smoke and toxic gases that complicate evacuation by blocking the exit access.

An interior exit stair (see definition of *exit* in 3.3.83) must be enclosed to be separated from other building spaces and to provide a protected way of travel to the exit discharge. If not properly enclosed, the exit not only fails to meet the definition of an exit but also creates an unprotected vertical opening. Thus, an exit stair must meet the requirements for enclosure of an exit (see 7.1.3.2), as well as those for protection of vertical openings in accordance with 8.6.5, as modified by the applicable occupancy chapter. Because the requirements for exit enclosures are more stringent than the requirements for protection of vertical openings, once the more stringent requirements have been met, the other requirements are usually met automatically.

The provisions of 8.6.5(4) through (6) reference the lodging or rooming, new hotel and dormitory, and new apartment building occupancy chapters, which permit modifications to the requirements of 8.6.5 under certain conditions. Some of the provisions permit 1-hour-rated enclosures, regardless of the number of stories connected, if the building is protected throughout by automatic sprinklers and is not a high-rise building. Although these occupancy chapters use such modifications to temper the basic Chapter 8 requirements with respect to the enclosure of vertical openings, it is possible for a specific occupancy chapter to be more stringent. For example, see 19.3.1.1, which requires 1-hour enclosures in existing health care occupancies rather than the ½-hour enclosures that would otherwise be permitted by 8.6.5(3).

**8.6.6 Communicating Space.** Unless prohibited by Chapters 11 through 43, unenclosed floor openings forming a communicating space between floor levels shall be permitted, provided that the following conditions are met:

- (1) The communicating space does not connect more than three contiguous stories.
- (2) The lowest or next-to-lowest story within the communicating space is a street floor.
- (3) The entire floor area of the communicating space is open and unobstructed, such that a fire in any part of the space will be readily obvious to the occupants of the space prior to the time it becomes an occupant hazard.
- (4) The communicating space is separated from the remainder of the building by fire barriers with not less than a 1-hour fire resistance rating, unless one of the following is met:
  - (a) In buildings protected throughout by an approved automatic sprinkler system in accordance with Section 9.7, a smoke barrier in accordance with Section 8.5 shall be permitted to serve as the separation required by 8.6.6(4).
  - (b) The requirement of 8.6.6(4) shall not apply to fully sprinklered residential housing units of detention and correctional occupancies in accordance with 22.3.1(2) and 23.3.1.1(2).
- (5) The communicating space has ordinary hazard contents protected throughout by an approved automatic sprinkler system in accordance with Section 9.7 or has only low hazard contents. (See 6.2.2.)
- (6) Egress capacity is sufficient to allow all the occupants of all levels within the communicating space to simultaneously egress the communicating space by considering it as a single floor area in determining the required egress capacity.
- (7)\* Each occupant within the communicating space has access to not less than one exit without having to traverse another story within the communicating space.
- (8) Each occupant not in the communicating space has access to not less than one exit without having to enter the communicating space.

**A.8.6.6(7)** Given that a mezzanine meeting the maximum one-third area criterion of 8.6.10.2.1 is not considered a story, it is permitted, therefore, to have 100 percent of its exit access within the communicating area run back through the story below.

Subsection 8.6.6 recognizes a vertical opening that is exempt from the normal enclosure requirements of 8.6.5 under the following two conditions:

1. The pertinent occupancy chapter for the occupancy type in question does not specifically prohibit use of the provision.
2. All of the protection criteria of 8.6.6(1) through (8) are met.

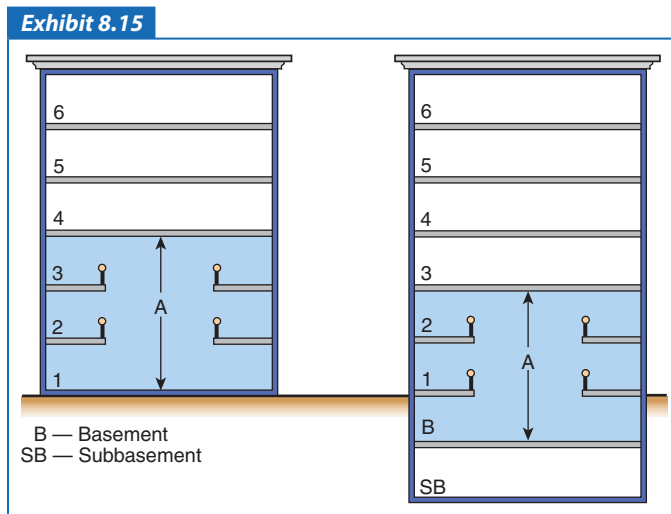

The provisions of 8.6.6 are often referred to as the “mini-atrium” requirements. Because they are limited to a maximum

three-story vertical opening, the requirements are not as stringent as those of 8.6.7, which apply to atria that can involve vertical openings that communicate among any number of stories. A two- or three-story communicating space can be adequately protected by the requirements of 8.6.6 without having to apply the more stringent requirements of 8.6.7. The fact that a two- or three-story space is labeled as an “atrium” on building plans does not necessarily mean that it must be protected by the requirements of 8.6.7. A two- or three-story vertical opening, irrespective of what it is called, is permitted to be protected per the requirements of 8.6.6, provided that doing so is not prohibited by the occupancy chapter(s) involved and the requirements of 8.6.6(1) through (8) are met.

Paragraphs 1 through 8, which follow, explain and illustrate the provisions of 8.6.6(1) through (8).

**1.** The vertical space cannot connect or communicate among more than three stories, and all connected stories are required to be contiguous to each other. However, the building housing the vertical opening in question is permitted to be more than three stories in height. For example, the vertical opening might communicate among floors 1 through 3, or floors B through 2, of a six-story building, as shown in Exhibit 8.15.

*Permitted location of three-story communicating space.*

**2.** The lowest of the maximum three communicating stories must be at, or not more than one level below, the street level. In other words, the vertical opening can communicate among only the first, second, and third floors or among the basement and first and second floors. See the space labeled A in Exhibit 8.15. As previously mentioned, additional building stories might be present either above or below the stories involving the communicating space, but these additional stories cannot be left open to the vertical opening. The more stringent set of provisions for atria per 8.6.7 should be considered where it is necessary or desirable either to have more than three

stories open or to locate the communicating stories such that the lowest story does not meet the placement requirement with respect to street level.

**3.** The communicating space includes all of the areas within the vertical opening itself and all of the adjoining areas left open to the vertical opening, as well as those areas not separated by minimum 1-hour fire barriers. The communicating space must be open and unobstructed, so that occupants within the communicating space will be aware of fire and smoke conditions emanating from any part of the communicating space prior to the time that such conditions become a hazard.

The provisions of 8.6.6 were originally written to recognize typical mercantile occupancy construction practices, which left partial, mezzanine-like floors open to the main street-level shopping floor below. These arrangements were sufficiently open so that, where coupled with the other provisions, they allowed sufficient time for the necessary awareness of emergency conditions and for occupants to use the egress system. These provisions were not intended to be used for an unenclosed stair. The size of the relatively small opening created by an unenclosed stair may be insufficient to provide occupants on all levels connected by the stair with the needed degree of awareness.

Between the two extremes of vast amounts of openness (as in the case of the mezzanine-like floors described in the previous paragraph) and little or no openness (as depicted by the unenclosed stair), judging sufficient openness can be difficult. Although not a Code-prescribed alternative, through the use of the equivalency concept addressed in Section 1.4, some authorities having jurisdiction have permitted complete automatic smoke detection systems with proper occupant notification features to be substituted for the openness and unobstructedness required by 8.6.6(3) for awareness and early warning purposes.

**4.** The communicating space must be separated from the remainder of the building by fire barriers with a minimum 1-hour fire resistance rating. Once the boundaries of the communicating space are established, based on determining how much area is open enough [per the requirement of 8.6.6(3) referenced in the previous paragraph] to allow awareness and early warning, then areas outside these boundaries must be separated from the communicating space associated with the vertical opening by barriers with a minimum 1-hour fire resistance rating. If the building is fully sprinklered, the barriers are permitted to be nonrated but must resist the passage of smoke and meet the other smoke barrier requirements of Section 8.5. It is assumed that the sprinkler system will control the fire and make fire resistance-rated barriers unnecessary. The smoke barriers will control the spread of smoke and help maintain a tenable means of egress route.

For example, consider a hotel building with guest room wings fanning out from the vertical opening. It can be assumed that the guest room wing corridors will need separation from the vertical opening, because occupants in the corridor on the second or third floor will not be readily aware of a fire on the first

floor before it becomes a hazard to their safety. The required 1-hour separation can be provided, while maintaining the perception of openness, by isolating the guest room wings from the vertical opening through the use of pairs of cross-corridor doors held open with automatic release devices. See [Exhibit 8.16](#).

5. If the communicating space (the vertical opening itself and all adjoining areas open to it, as described in the first paragraph of item 3) contains *ordinary hazard contents* (as specified in [Section 6.2](#) of this Code, as opposed to *ordinary hazard occupancies* as defined in NFPA 13, *Standard for the Installation of Sprinkler Systems*),<sup>38</sup> all areas within the confines of the communicating space must be protected by automatic sprinklers. If the contents are *low hazard contents* (as specified in [Section 6.2](#) of this Code, rather than *light hazard occupancies* as defined in NFPA 13), no sprinkler system is required by [8.6.6](#). However, as intended by [Section 6.2](#), most occupancies contain ordinary hazard contents. Because only low hazard and ordinary hazard contents are addressed in [8.6.6\(5\)](#), high hazard contents are not permitted in communicating spaces in accordance with [8.6.6](#).

Although sprinkler system protection is required with ordinary hazard contents, only the communicating space (as previously defined) needs to be sprinklered, as specified by [8.6.6\(5\)](#). The sprinkler system should cover all areas within the boundaries established by the 1-hour fire barriers or smoke barriers that are required by [8.6.6\(4\)](#). See [Exhibit 8.16](#).

In [Exhibit 8.16](#), the cross-corridor fire doors might be held open by automatic release devices so that the corridor appears to be open to the communicating area of the vertical opening. Yet, because there are doors and a barrier at that location, they demarcate the boundary between the communicating space and the floor area outside the communicating space. Sprinkler

protection must be provided for the vertical opening and all areas up to the 1-hour fire barriers.

6. Because all occupants within the communicating space might be exposed within a short time to the effects of a fire, simultaneous evacuation capability needs to be provided. Thus, the combined occupant load for all spaces, on all levels, within the boundaries of the communicating space needs to be included when sizing the means of egress for the communicating space. This requirement is more stringent than the provision of [7.3.1.4](#), which does not require the accumulation of occupant loads from various floors when determining the required egress capacity for exit stairs.

7. Per the requirements of [8.6.6\(3\)](#) and (4), the communicating space is that space that is sufficiently open to the vertical opening to allow ready awareness of fire conditions on that and other levels within the communicating space. Areas that are remote enough from the vertical opening to lose the requisite awareness must be located on the other side of 1-hour fire barriers (or smoke barriers if the building is fully sprinklered) and are considered to be outside the communicating space. Thus, in a typical office building making use of the provisions of [8.6.6](#), for example, some occupants work and are normally stationed within the communicating space, while others work and are stationed outside the communicating space. Such an arrangement is shown in [Exhibit 8.17](#).

Occupants located within the communicating space must have access to at least one exit without having to traverse another story within the communicating space per [8.6.6\(7\)](#). The communicating space shown in [Exhibit 8.17](#) meets this requirement by allowing occupants to travel horizontally across the communicating space, pass through the doors in the fire-rated barrier or smoke barrier into one of the building wings designated as “floor area outside communicating space,” and continue

**Exhibit 8.16**

Separation of three-story communicating space from remainder of building.

**Exhibit 8.17**

Exit access arrangement for building using the three-story communicating space provision.

to that wing's enclosed exit stair. In other words, the occupants of the communicating space are not permitted to use the open stairs exclusively to travel to another level of the communicating space to reach the required exits.

In the example illustrated in [Exhibit 8.17](#), assume that some occupants of the communicating space are farther from either of the enclosed exit stairs, which are located at each end of the building, than the travel distance permitted by other *Code* requirements. Further, assume that those same occupants of the communicating space can travel down the open stair and across the bottom floor of the vertical opening to an exterior exit door within the permitted travel distance limitation. The open stair, although it is not an exit, could be considered as exit access, and the door to the outside at the lowest level of the vertical opening could then be regarded as the nearest *Code*-complying exit for those occupants. Any of the enclosed exit stairs located outside the communicating space could then serve as the second exit for those occupants of the communicating space. The enclosed exit stairs would then serve the following three purposes, none of which would include use as the primary exit for those occupants of the communicating space:

- a. The stairs would satisfy the requirements of the business occupancy chapters that not less than two exits must be provided on every story.
- b. Either stair would satisfy the requirement of [8.6.6\(7\)](#) that the occupants of the communicating space have access to at least one exit without having to traverse another story within the communicating space, provided that the doors are not subject to locking.
- c. Each stair would satisfy the requirement of [8.6.6\(8\)](#), discussed in the commentary that follows in paragraph 8, which mandates that each occupant not located within the communicating space is to have access to at least one exit without entering the communicating space.

8. Although all occupants must have access to two separate exits, the occupants who are located on any of the maximum of three floors that are permitted to communicate with the vertical opening, but who are not within the communicating space (as illustrated in [Exhibit 8.17](#) by the areas identified as "floor area outside communicating space"), must be able to reach one of the two required exits without entering the communicating space. Locating an enclosed exit stair within each of the floor areas outside the communicating space satisfies this requirement.

The provisions of [8.6.6](#) are permitted to be utilized, unless prohibited by the applicable occupancy chapter. For an example of an occupancy that prohibits use of the communicating space specified by [8.6.6](#), see [18.3.1.5](#) and [19.3.1.5](#), which apply to new and existing health care occupancies, respectively. Thus, if a health care occupancy is to have a three-story unprotected vertical opening, it must comply with the more stringent atrium requirements of [8.6.7](#). For an example of an occupancy that provides requirements in addition to those of [8.6.6\(1\)](#) through (8),

see [14.3.1.2](#) and [15.3.1.2](#), which apply to new and existing educational occupancies, respectively. [Chapters 14](#) and [15](#) require that the entire building, rather than only the communicating space, be protected by a supervised automatic sprinkler system.

**8.6.7\* Atriums.** Unless prohibited by [Chapters 11](#) through [43](#), an atrium shall be permitted, provided that all of the following conditions are met:

- (1) The atrium is separated from the adjacent spaces by fire barriers with not less than a 1-hour fire resistance rating, with opening protectives for corridor walls, unless one of the following is met:
  - (a) The requirement of [8.6.7\(1\)](#) shall not apply to existing, previously approved atriums.
  - (b) Any number of levels of the building shall be permitted to open directly to the atrium without enclosure, based on the results of the engineering analysis required in [8.6.7\(5\)](#).
  - (c)\* Glass walls and inoperable windows shall be permitted in lieu of the fire barriers where all the following are met:
    - i. Automatic sprinklers are spaced along both sides of the glass wall and the inoperable windows at intervals not to exceed 6 ft (1830 mm).
    - ii. The automatic sprinklers specified in [8.6.7\(c\)i](#) are located at a distance from the glass wall not to exceed 12 in. (305 mm) and arranged so that the entire surface of the glass is wet upon operation of the sprinklers.
    - iii. The glass wall is of tempered, wired, or laminated glass held in place by a gasket system that allows the glass framing system to deflect without breaking (loading) the glass before the sprinklers operate.
    - iv. The automatic sprinklers required by [8.6.7\(c\)i](#) are not required on the atrium side of the glass wall and the inoperable window where there is no walkway or other floor area on the atrium side above the main floor level.
    - v. Doors in the glass walls are of glass or other material that resists the passage of smoke.
    - vi. Doors in the glass walls are self-closing or automatic-closing upon detection of smoke.
    - vii. The glass is continuous vertically, without horizontal mullions, window treatments, or other obstructions that would interfere with the wetting of the entire glass surface.
- (2) Access to exits is permitted to be within the atrium, and exit discharge in accordance with [7.7.2](#) is permitted to be within the atrium.
- (3) The occupancy within the atrium meets the specifications for classification as low or ordinary hazard contents. (*See* [6.2.2.](#))

- (4) The entire building is protected throughout by an approved, supervised automatic sprinkler system in accordance with [Section 9.7](#).
- (5)\* For other than existing, previously approved atriums, an engineering analysis is performed that demonstrates that the building is designed to keep the smoke layer interface above the highest unprotected opening to adjoining spaces, or 6 ft (1830 mm) above the highest floor level of exit access open to the atrium, for a period equal to 1.5 times the calculated egress time or 20 minutes, whichever is greater.
- (6)\* For other than existing, previously approved smoke control systems, where an engineered smoke control system is installed to meet the requirements of [8.6.7](#), the system is independently activated by each of the following:
  - (a) Upon actuation of the required automatic sprinkler system within the atrium or areas open to the atrium
  - (b) Manual controls that are readily accessible to the fire department

**A.8.6.7** Where atriums are used, there is an added degree of safety to occupants because of the large volume of space into which smoke can be dissipated. However, there is a need to ensure that dangerous concentrations of smoke are promptly removed from the atrium, and the exhaust system needs careful design. For information about systems that can be used to provide smoke protection in these spaces, see the following:

- (1) NFPA 92, *Standard for Smoke Control Systems*
- (2) *Principles of Smoke Management*

**A.8.6.7(1)(c)** The intent of the requirement for closely spaced sprinklers is to wet the atrium glass wall to ensure that the surface of the glass is wet upon operation of the sprinklers, with a maximum spacing of sprinklers of 6 ft (1830 mm) on centers. Provided that it can be shown that the glass can be wet by the sprinklers using a given discharge rate, and that the 6 ft (1830 mm) spacing is not exceeded, the intent of the requirement is met. It is important that the entire glass area surface is wet. Due consideration should be given to the height of the glass panels and any horizontal members that might interfere with sprinkler wetting action.

**A.8.6.7(5)** See NFPA 92, *Standard for Smoke Control Systems*. The engineering analysis should include the following elements:

- (1) Fire dynamics, including the following:
  - (a) Fire size and location
  - (b) Materials likely to be burning
  - (c) Fire plume geometry
  - (d) Fire plume or smoke layer impact on means of egress
  - (e) Tenability conditions during the period of occupant egress
- (2) Response and performance of building systems, including passive barriers, automatic detection and extinguishing, and smoke control

- (3) Response time required for building occupants to reach building exits, including any time required to exit through the atrium as permitted by [8.6.7](#)

**A.8.6.7(6)** Activation of the ventilation system by manual fire alarms, extinguishing systems, and detection systems can cause unwanted operation of the system, and it is suggested that consideration be given to zoning of the activation functions so the ventilation system operates only when actually needed.

Atria are permitted in accordance with [8.6.7](#), unless prohibited by the applicable occupancy chapter. Although no occupancy chapter currently prohibits atria, some impose additional limitations. For example, health care occupancies prohibit the open floors addressed by [8.6.7\(1\)\(b\)](#) from involving patient sleeping and treatment rooms. Thus, there would need to be, at a minimum, a smoke-resisting membrane, such as a glass window, between the patient room and the atrium space.

[Exhibit 8.18](#) and [Exhibit 8.19](#) illustrate a typical atrium.

The provisions of [8.6.7](#) address a vertical opening that communicates among more than the three stories addressed by the communicating space, or “mini-atrium,” provisions of [8.6.6](#). Although the atrium provisions are not prohibited from being used for two- or three-story atrium-like vertical openings, the

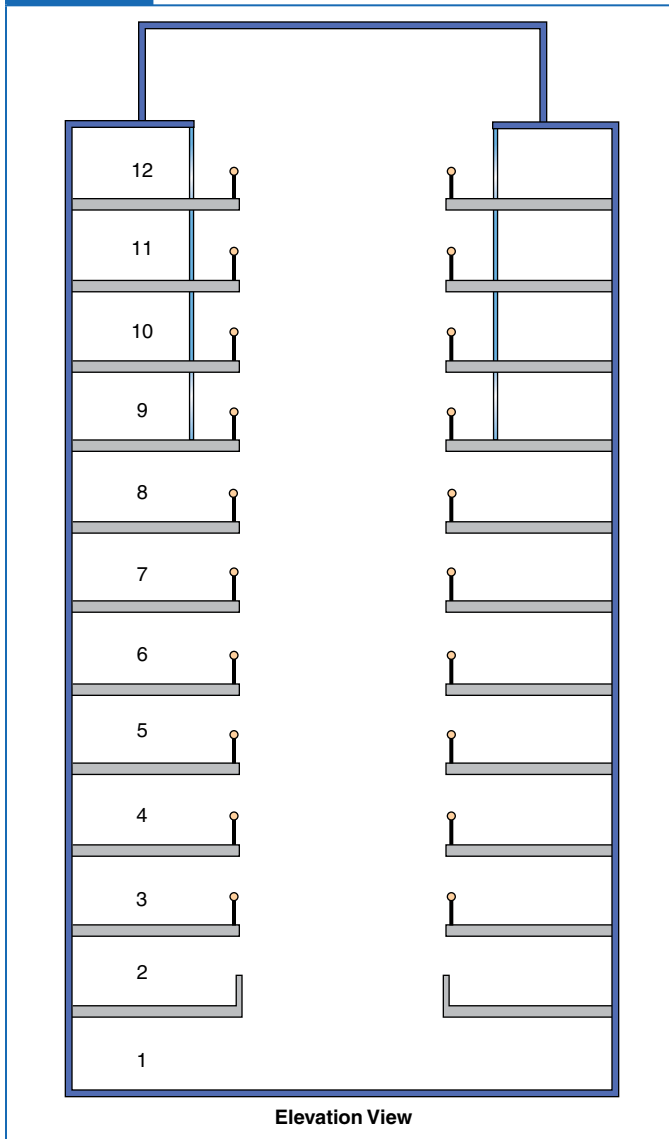

**Exhibit 8.18**

Plan view of a typical atrium.

Exhibit 8.19

Elevation view of a typical atrium.

provisions of 8.6.6 should adequately protect a two- or three-story “mini-atrium.” The design professional should be permitted to protect such areas in accordance with the less stringent provisions of 8.6.6, provided that the occupancy chapter in question does not prohibit doing so. For example, 18.3.1.5 and 19.3.1.5, which address the protection of vertical openings in new and existing health care occupancies, respectively, prohibit the use of the communicating space provisions of 8.6.6. Thus, in health care occupancies, a two- or three-story atrium-like vertical opening is permitted only if it meets all of the requirements of 8.6.7 applicable to atria. For certain designs, 8.6.6 might not be desirable due to its restriction on exit access within the vertical opening. For example, the designers of a three-story hotel might prefer to use the more stringent provisions of 8.6.7, because they

would permit the guest rooms to have exit access through the atrium, whereas 8.6.6 would not permit exit access to be solely through the communicating space.

The protection requirements of 8.6.7(1) through (6) are explained and illustrated in paragraphs 1 through 6, which follow.

1. In accordance with the requirements of 8.6.5(1), a vertical opening of four or more stories in new construction generally must be separated from the rest of the building by an enclosure of 2-hour fire barriers. However, the atrium provisions work together as an overall package in permitting the construction that separates other areas of the building from the atrium to be reduced to 1-hour fire barriers. Further, the doors in the 1-hour atrium fire barrier are permitted to be 20-minute fire protection-rated assemblies, as permitted for corridor doors. Thus, the intent of the 1-hour separation requirement is mainly to provide a carefully constructed, smoke-resistant barrier.

Per 8.6.7(1)(b), any number of levels is permitted to be left open to the atrium, based on the engineering analysis required in 8.6.7(5). In Exhibit 8.20, floors 2 through 5 have been left open to the atrium. (In Exhibit 8.19, the open levels occur on floors 1 through 8.) Some occupancy chapters modify the atrium requirements to afford the users of those occupancies the level of life safety needed. For example, for health care occupancies, Chapters 18 and 19 limit the location of the open levels permitted by 8.6.7(1)(b) so that patient treatment and sleeping rooms are not left open to the atrium.

Exhibit 8.20

Floor levels open to atrium.

To allow visual contact between the atrium and floors that have not been proven by engineering analysis to warrant openness, 8.6.7(1)(c) permits a smoke-resisting separation consisting of glass walls, vision panels, and windows in lieu of 1-hour-rated fire barriers. The intent of the requirement for directing closely spaced sprinklers at the glass walls is explained in A.8.6.7(1)(c).

The concept of wetting the glass that is exposed to a fire, without specifying a water application rate, is similar to boiling water in a Pyrex® container over an open flame. As long as some water is in the container to absorb the heat, the glass itself does not reach excessive temperatures that would cause failure. To ensure that water will reach the surface of the glass, window blinds and draperies must not be placed between the line of closely spaced sprinklers and the glass. Careful design will allow for the sprinklers to be placed close enough to the glass so that blinds and draperies can be installed using normal installation practice.

The permission to omit lines of closely spaced sprinklers on the atrium side of glass walls, which are to be used in lieu of 1-hour fire barriers, is intended to apply to the floor levels above the atrium main floor level. In other words, if glass walls are used on the main floor level in lieu of a 1-hour fire barrier, sprinklers must be installed on both sides of the glass at that level, because combustibles might be placed on the floor on the atrium side of the glass. A similar condition occurs on floors 6, 7, and 8 of Exhibit 8.20, where combustibles could be placed on the balcony floor adjacent to the glass.

2. The exit stairs must be enclosed in accordance with the exit enclosure requirements of 7.1.3.2, although they are permitted to be within the atrium and located so as to require building occupants to walk through the atrium in order to gain access to them. Exhibit 8.18 shows three such exit stair enclosures located within the atrium, with all occupants of the floor required to traverse the atrium, along the interior exit access balcony, to gain access to the stairs. Up to 50 percent of the three exits — that is, one exit in the given example — is permitted to discharge occupants from upper or lower floors through interior building areas in accordance with 7.7.2, potentially forcing some occupants to walk across the floor of the atrium to reach an exit to the outside. The stringent requirements of 8.6.7(1) through (6) ensure an adequate overall life safety package, allowing the exit access and as much as half of the exit discharge to be within the atrium.

3. The occupancy within the atrium [the vertical opening and all floor areas left open to the vertical opening, such as balcony-like walking surfaces and the levels permitted to be left completely open via the provisions of 8.6.7(1)(b)] is limited to low hazard or ordinary hazard contents, as addressed in 6.2.2. High hazard contents are thus prohibited from being placed within the atrium but could be within rooms protected as hazardous areas in accordance with Section 8.7 and the \_\_\_3.2 subsection of the applicable occupancy chapter. Because the provisions of 8.6.7(4) require that the building be completely protected by an approved, supervised automatic sprinkler

system, the presence of only low hazard contents within the atrium does not exempt the space from the requirement for sprinklers in the atrium. Conversely, in accordance with the communicating space or “mini-atrium” provisions of 8.6.6, such an exemption is permitted.

4. The entire building, not only the atrium space, must be protected by an approved, supervised automatic sprinkler system meeting the requirements of Section 9.7. Assuming that the atrium is located in a hotel building of five or more stories, for example, the provisions of Section 9.7 require the sprinkler system to meet the requirements of NFPA 13, *Standard for the Installation of Sprinkler Systems*.

A question that sometimes arises is whether sprinklers are required, or whether they will be effective, at the ceilings of atria, which can be very high relative to the floor level. Prior to the 1997 edition of the *Code*, an exception allowed the authority having jurisdiction to permit the omission of sprinklers at the tops of atria where the ceiling height was greater than 55 ft (17 m) above the floor. This exception was removed for the 1997 and subsequent editions because there is no scientific evidence to suggest that sprinklers are ineffective at such heights. In fact, data submitted to the technical committee responsible for these provisions indicate that sprinklers can effectively extinguish or control fires at heights on the order of 100 ft (30 m) above the floor. Neither this *Code* nor NFPA 13 permits the omission of sprinklers from the ceilings of atria.

5. An engineered smoke control or smoke removal system acceptable to the authority having jurisdiction has been required since the atrium provisions were first introduced into the *Life Safety Code* in the 1981 edition. As advisory, but nonmandatory, information, the appendix of earlier editions suggested that, depending on atrium height and volume, either four or six air changes per hour could provide the smoke exhaust rate needed to meet the tenability conditions intended by the requirement for atrium smoke control.

The guideline for six air changes per hour came to be considered law by many authorities having jurisdiction and was thus accepted as the norm by many system designers. Authorities having jurisdiction then subjected such systems to acceptance testing using smoke bombs that produce cold smoke, which does not have the heat, buoyancy, and entrainment of air from a real fire. The acceptance criteria were further complicated by those who mistakenly believed that the intent of the smoke control requirement was, for example, that no smoke be visible within the atrium at the end of a 10-minute test. Designers found that, to ensure that the acceptance test could be passed, the system should provide approximately 10 to 12 air changes per hour. In effect, atria smoke control systems were typically designed to pass the acceptance test with no consideration or assurance of effective smoke control under real fire conditions. NFPA 92, *Standard for Smoke Control Systems*, warns that a system designed in accordance with NFPA 92 and capable of providing the intended smoke management might not pass

smoke bomb tests.<sup>39</sup> Conversely, it is possible for a system that is incapable of providing the intended smoke management to pass smoke bomb tests. Because of the impracticality of conducting real fire tests within an atrium, the acceptance tests described in NFPA 92 are directed at those aspects of smoke management systems that can be verified through direct measurement.

Using performance-based criteria, 8.6.7(5) requires that an engineering analysis be performed to demonstrate that smoke will be managed for the time needed to evacuate the building. To accomplish this, 8.6.7(5) requires the analysis to prove that the smoke layer interface will be maintained above the highest unprotected opening to adjoining spaces, or 6 ft (1830 mm) above the highest floor level of exit access open to the atrium for a time equal to  $1\frac{1}{2}$  times the calculated egress time or 20 minutes, whichever is greater. For a protect-in-place occupancy, such as health care, the evacuation time is considered to be infinite, which means that the smoke control performance criteria must be maintained indefinitely.

In Exhibit 8.19, floors 1 through 8 are open to the atrium and floors 9 through 12 use the atrium balconies for exit access. An engineering analysis will most likely determine that a high-capacity smoke management system will be needed to meet the performance-based criteria for maintaining the smoke layer interface 6 ft (1830 mm) above the walking surface of the twelfth-floor exit access balcony (the highest floor level with exit access in the atrium). The smoke control system will need to begin removing smoke early in the fire, because there is little accumulation capacity in the space above the twelfth floor and beneath the ceiling of the atrium. Contrast this situation with that shown in Exhibit 8.21, in which floors 10 through 12 do not use the atrium for exit access. Although a smoke control system will be needed to meet the performance-based smoke control criteria, the system might be of a less aggressive design, given

that the smoke can bank down from the ceiling of the atrium to below the tenth floor before affecting occupant egress.

NFPA 92 quantifies the physics associated with atrium smoke control and presents methodologies for system design in an understandable and useful format. The requirements of NFPA 92 allow the system designer to design a system and prepare the associated documentation for the AHJ to assess for adequacy in meeting the performance criteria of 8.6.7(5). For example, the designer and the AHJ agree that an acceptable design must provide for the level of smoke filling to be maintained at least 6 ft (1830 mm) above the highest floor level open to the atrium and the highest floor level used for exit access within the atrium for a minimum of 20 minutes after actuation of the fire alarm system.

The following example, which is illustrated in Exhibit 8.21, makes use of the provisions of NFPA 92 in designing a smoke management system that meets the smoke-filling criterion agreed to by the designer and the AHJ.

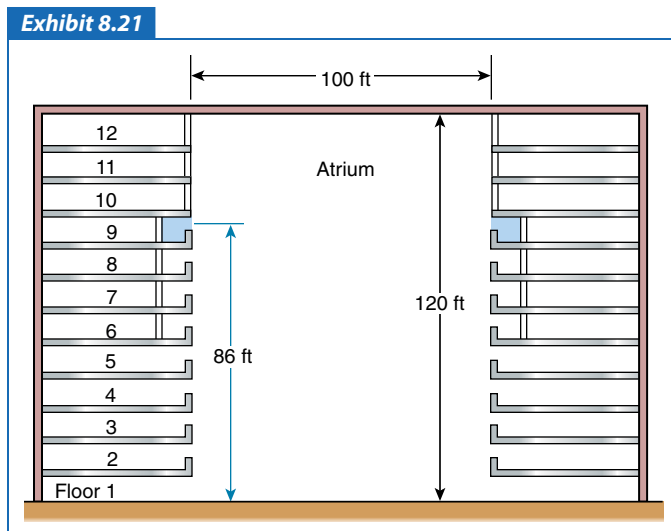

Note that the following example and analysis use the formulae from those portions of NFPA 92 that use the conventional U.S. customary units (e.g., feet, square feet, Btu per second, pounds per cubic foot, cubic feet per minute). Although it is standard practice within this handbook to provide metric or SI units, SI equivalents are not provided in the calculations that follow. Rather, the reader is referred to NFPA 92, where SI unit forms of all 22 equations used in the standard are available.

The proposed atrium building is to be 12 stories in height, with the fifth floor as the highest level open to the atrium and the ninth floor as the highest walking level within the atrium. Further, the atrium ceiling is to be 120 ft above the floor; the atrium opening is to be rectangular with horizontal dimensions of 100 ft  $\times$  200 ft; and the atrium is to be furnished with upholstered furniture and wood and plastic tables characteristic of the fire loading typically associated with a business occupancy.

If the designer prefers to install spot smoke detectors for activation of the smoke control system and initiation of the building fire alarm at the top of the atrium only, the designer would need to determine if smoke will reach the ceiling or stratify at a given distance below the ceiling in the case of the selected design fire. Stratification occurs when the temperature of the rising plume equals the temperature of the surrounding air and the fire has insufficient energy to “push” the smoke layer any higher.

Computational methods, which are beyond the scope of this analysis, are available for determining the potential for stratification below the atrium ceiling. For example, in an atrium that is known to have a discrete ambient temperature change at a given elevation above the floor level (perhaps due to solar loading), the designer can determine the height at which the fire plume centerline temperature equals the ambient temperature. Stratification can be assumed to occur at that height. See Annex E of NFPA 92 for additional discussion on stratification.

To further compound the issue, detection of smoke by spot-type detectors at ceiling heights greater than 30 ft requires its own engineering analysis, which is also beyond the scope of this

Twelve-story atrium for which smoke control is to be provided.

example. For such analyses, consult Schifiliti and Pucci's "Fire Detection Modeling, State of the Art."<sup>40</sup>

Stratification is not a concern after the smoke management system activates, because the natural buoyancy of the smoke (or lack thereof) will be negligible compared to the pressure differences and air movement created by the system. Stratification can, however, have a significant adverse effect on the time to system initiation from the start of the fire. The designer might wish to design the detection system for activation of the smoke management system in a manner that ensures prompt detection, regardless of the ambient conditions in the atrium at the time of the fire. Projected-beam smoke detectors, which are capable of measuring the light obscuration caused by smoke particles, can be arranged to quickly detect either a developing smoke layer or the rising smoke plume. In either case, a series of beam detectors is to be installed at strategic points within the atrium. Projected-beam smoke detectors can be arranged to provide a highly reliable means of detecting a fire within the atrium in its early stages. In all cases, the requirements of NFPA 72, *National Fire Alarm and Signaling Code*, and the detector manufacturer's installation guidelines should be followed.

For the remainder of this example, it is assumed that the atrium is provided with projected-beam smoke detectors arranged to activate the smoke management system and initiate the building fire alarm relatively quickly following the onset of fire, and before the smoke level descends to within 6 ft of the highest level of exit access open to the atrium.

Having equated the furniture arrangement as typical of the combustible loading associated with a business occupancy, the designer feels comfortable assuming a typical heat release rate per unit floor area of 20 Btu/ft<sup>2</sup>-s, which realistically translates to a design fire heat release rate,  $Q$ , from steady fire of 5000 Btu/s. The convective portion of the heat release rate,  $Q_c$ , can be estimated as 70 percent of the heat release rate,  $Q$ .

The designer next calculates the volumetric exhaust rate required to keep smoke 86 ft above the atrium floor (i.e., 6 ft above the highest walking level in the atrium, which, in this case, is the ninth floor balcony, whose floor is at the 80 ft elevation). From the provisions of NFPA 92, the designer locates the design fire in the center of the floor of the atrium so as to keep the fire away from the walls and, thus, create the worst-case condition. With the fire at the center of the atrium floor, an axisymmetric fire plume is expected for which air is entrained from all sides and along the entire height of the plume, until the plume becomes submerged in the smoke layer (see Exhibit 8.22). This leads the designer to the use of equation 5.5.1.1a of NFPA 92 to determine the flame height, as follows:

$$z_l = 0.533Q_c^{2/5}$$

where:

- $z_l$  = limiting elevation (ft)
- $Q_c$  = convective portion of heat release rate (Btu/s), established previously as 70 percent of the heat release rate,  $Q$

Exhibit 8.22

Axisymmetric fire plume and associated smoke interface.

In this case,

$$Q_c = 0.7(5000 \text{ Btu/s}) = 3500 \text{ Btu/s}$$

Substituting gives

$$z_l = 0.533(3500)^{2/5} = 13.9 \text{ ft}$$

With the design interface of the smoke layer at 86 ft above the floor level, the flame height is less than the design smoke layer height. Thus, equation 5.5.1.1b of NFPA 92 can be used to determine the smoke production rate at the height of the smoke layer interface as follows:

$$m = [0.022Q_c^{1/3} z^{5/3}] + 0.0042Q_c \text{ (for } z = z_l)$$

where:

- $m$  = smoke production rate at height of smoke layer interface (lb/s)
- $Q_c$  = convective portion of heat release rate (Btu/s)
- $z$  = height above the fuel (ft)

In this case,

$$Q_c = 3500 \text{ Btu/s, as developed in previous calculations}$$

$$z = 86 \text{ ft (i.e., 6 ft above the 80 ft walking surface)}$$

Substituting gives

$$m = 0.022(3500)^{1/3}(86)^{5/3} + 0.0042(3500) = 574 \text{ lb/s}$$

If the smoke exhaust rate is equal to the smoke production rate, the smoke layer depth will be stabilized at the design height (i.e., the 86 ft elevation) and, thus, all balconies and areas open to the atrium will remain tenable as the fire continues to burn.

Before converting the smoke production rate to a volumetric flow rate, it is necessary to determine the temperature rise above ambient of the smoke at time of venting in order to establish the density of the smoke during the vented stage. As explained by the last note in Table D.1.3 of NFPA 92, the maximum temperature rise will occur if the total heat loss factor is equal to zero. Use the vented stage temperature rise formula from Table D.1.3, simplified by setting the total heat loss factor equal to zero, to determine  $\Delta T$  as follows:

$$\Delta T = \frac{60 Q_c}{(\rho c V)}$$

which, as shown in equation 5.5.5 of NFPA 92, can be reduced to

$$\Delta T = \frac{Q_c}{mc}$$

where:

- $\Delta T$  = temperature rise above ambient of smoke at time of venting (°F)
- $Q_c$  = 3500 Btu/s, as developed in previous calculations
- $m$  = 574 lb/s, as developed in previous calculations
- $c$  = 0.24 Btu/lb-°F, specific heat of smoke, assuming smoke equals air

Substituting gives

$$\begin{aligned} \Delta T &= \frac{300}{574(0.24)} \\ &= 25^\circ\text{F} \end{aligned}$$

Assuming ambient temperature of 68°F, the temperature of smoke is  $T_s = 25 + 68 = 93^\circ\text{F}$ .

Using equation 5.8a of NFPA 92, the density of smoke at 93°F can be calculated as follows:

$$\rho = \frac{144 P_{atm}}{R(T + 460)}$$

where:

- $\rho$  = density of heated smoke (lb/ft<sup>3</sup>)
- $P_{atm}$  = atmospheric pressure (lb/in.<sup>2</sup>) (for this example, use standard atmospheric pressure: 14.7 lb/in.<sup>2</sup>)
- $R$  = gas constant (53.34)
- $T$  = temperature of smoke (°F)

Substituting gives

$$\begin{aligned} \rho &= \frac{[144(14.7)]}{[53.34(93 + 460)]} \\ &= 0.0717 \text{ lb/ft}^3 \end{aligned}$$

The smoke production rate can be converted to a volumetric flow rate using equation 5.7a of NFPA 92 as follows:

$$V = 60 \frac{m}{\rho}$$

where:

- $V$  = volumetric flow rate (ft<sup>3</sup>/min)
- $m$  = smoke production rate, 574 lb/s as previously calculated
- $\rho$  = density of heated smoke, 0.0717 lb/ft<sup>3</sup> as previously calculated

Substituting gives

$$\begin{aligned} V &= 60 \left[ \frac{574}{0.0717} \right] \\ &= 480,335 \text{ ft}^3/\text{min} \end{aligned}$$

The preceding calculations assume that the smoke plume has not widened to contact the walls of the atrium prior to reaching the design interface height of 86 ft above the atrium floor in this example. As a plume rises, it also widens. If the plume were to contact all of the walls of the atrium prior to reaching the ceiling, the smoke interface would be considered as occurring at the height of contact with all of the surrounding walls. No additional smoke generation can be assumed to occur above that height, because additional air entrainment into the plume is considered to be negligible above the point of contact. To check if the widening plume has contacted the walls of the atrium, equation 5.5.4.1 of NFPA 92 can be used to predict the total plume diameter, at the interface height, as follows:

$$\begin{aligned} d &= 0.5z \\ d &= 0.5(86) \\ &= 43 \text{ ft} \end{aligned}$$

where:

- $d$  = plume diameter (ft)
- $z$  = interface height (ft)

Thus, in this 100 ft × 200 ft atrium area, the smoke does not contact the walls prior to reaching the design interface height of 86 ft. Mechanical systems capable of extracting approximately 480,000 ft<sup>3</sup>/min are then designed. The substantiation package is submitted to the authority having jurisdiction for approval.

Acceptance testing of the system then involves verifying the function of the system components in the intended sequence for varying initiation scenarios. In addition, the system should be evaluated by measuring the following:

1. Total volumetric flow rate
2. Airflow velocities
3. Airflow direction
4. Door-opening forces (forces permitted by the *Code* must not be exceeded when the smoke management system is operating)
5. Pressure differences
6. Ambient indoor and outdoor temperatures
7. Wind speed and direction

If the measurements are within the previously agreed upon system design specifications, the system should be deemed as passing. Note again that no reference is made to the use

of subjective test criteria, such as cold smoke bombs. The measurements are obtained objectively and can be performed by professional mechanical, HVAC, or fire protection engineers. NFPA 92, offers detailed provisions on the equipment needed and procedures for conducting acceptance tests on engineered smoke management systems.

6. The provisions of 8.6.7(6) address the activation of smoke control systems that might be designed to meet the performance-based requirements of 8.6.7(5). In some buildings that have large atrium openings but no upper floors open to the atrium, and no exit access on those upper floors through the atrium, and that are used by ambulatory occupants, it might be possible to meet smoke control criteria without any mechanical systems by allowing smoke to accumulate within the large volume atrium space above the heads of occupants. The purpose of the engineering analysis required by 8.6.7(5) is to determine which type of mechanical smoke control, if any, is needed. Alternatively, tenability of the means of egress might be able to be maintained through passive ventilation of the atrium. The required engineering analysis should evaluate several protection scenarios.

As addressed by A.8.6.7(6), automatic activation of the atrium smoke management system, especially upon initiation of the fire alarm system via operation of a manual fire alarm box, could result in the activation of the smoke management system in the incorrect mode. For example, a building occupant walking along the sixth-floor exit access balcony within the atrium might see flames and smoke on the third floor, which is open to the atrium. The occupant might walk to the exit stair enclosure on the sixth floor and operate the manual fire alarm box. The building fire alarm system might incorrectly assume that the fire is on the sixth level. The third floor, which is the actual fire floor, might incorrectly be identified as a non-fire floor. The smoke management system might positively pressurize the third floor and move large volumes of air across the third-floor opening into the atrium in an effort to keep smoke from entering the third-floor communicating space. In reality, the smoke management system would accomplish exactly the opposite of that which it was designed to do; it would spread the smoke and other products of combustion from the third-floor fire into the atrium. The sixth floor would mistakenly be negatively pressurized (exhausted) and would pull in the smoke and gases from the third-floor fire via the atrium. For this reason, NFPA 92 requires smoke management systems to activate only via automatic initiating devices, such as smoke detectors and automatic sprinklers. However, controls for manual operation of the system by the fire department are required by 8.6.7(6)(b). Smoke management systems should not be arranged to activate via manual fire alarm boxes that are accessible to building occupants.

The manual controls required by 8.6.7(6)(b) must be readily accessible to the responding fire department personnel, so that the smoke management system's mode of operation can be overridden and tailored to the specific needs of the emergency

responders. These and other concepts on effective smoke management are covered in NFPA 92.

**8.6.8 Two-Story Openings with Partial Enclosure.** A vertical opening serving as other than an exit enclosure, connecting only two adjacent stories and piercing only one floor, shall be permitted to be open to one of the two stories.

Subsection 8.6.8 recognizes a maximum two-story stair or other vertical opening that is enclosed on one of the two floors, but not both. The separating barrier prevents the smoke, heat, and other toxic products of combustion from a fire on one of the two levels from spreading to the other floor. Because the stair is not an exit, this arrangement does not violate the requirements of 7.1.3.2 pertaining to exit enclosures. Exhibit 8.23 illustrates a non-exit stair that is open on floor 3 but separated on floor 2. As an alternative, the stair could be separated from floor 3 and open to floor 2. A stair meeting 8.6.8 might be permitted to be used for exit access, but it is not permitted to be considered an exit because it is not enclosed on all levels.

Exhibit 8.23

Vertical opening protection by fire barrier at one floor level only.

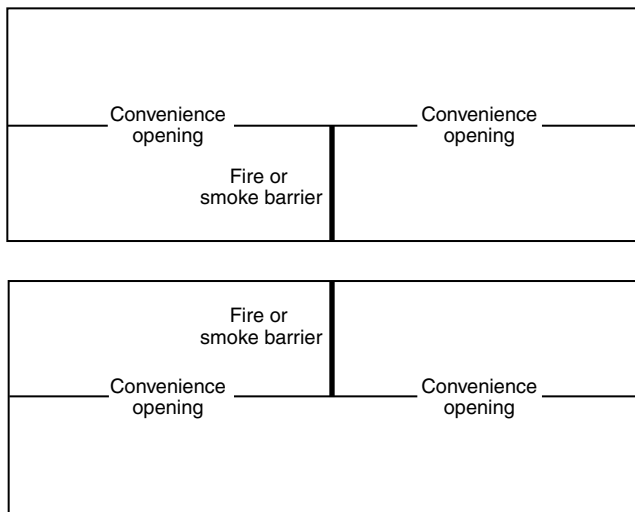

## 8.6.9 Convenience Openings.

8.6.9.1 Where permitted by Chapters 11 through 43, unenclosed vertical openings not concealed within the building construction shall be permitted as follows:

- (1) Such openings shall connect not more than two adjacent stories (one floor pierced only).
- (2) Such openings shall be separated from unprotected vertical openings serving other floors by a barrier complying with 8.6.5.
- (3) Such openings shall be separated from corridors.

- (4)\* In other than approved, existing convenience openings, such openings shall be separated from other fire or smoke compartments on the same floor.
- (5) In new construction, the convenience opening shall be separated from the corridor referenced in 8.6.9.1(3) by a smoke partition, unless Chapters 11 through 43 require the corridor to have a fire resistance rating.
- (6)\* Such openings shall not serve as a required means of egress.

**A.8.6.9.1(4)** The intent of this requirement is to prohibit a communication of two compartments on the same floor via two convenience openings. This is represented in Figure A.8.6.9.1(4).

**Figure A.8.6.9.1(4)** Examples of Convenience Openings That Communicate with Two Compartments on Same Floor in Violation of 8.6.9.1(4).

**A.8.6.9.1(6)** This requirement prohibits means of egress down or up the convenience opening. It does not prohibit means of escape from running down or up the convenience opening within residential dwelling units.

The provisions of 8.6.9.1 address a convenience opening, often taking the form of a convenience stair, which many of the occupancy chapters have recognized for many years. The occupancy chapters can reference the provisions of 8.6.9.1 without the need to repeat the detailed criteria. For example, 38.3.1.1(1), which applies to new business occupancies, permits "unenclosed vertical openings in accordance with 8.6.9.1." This permits, for example, a two-level office or reference library in an office building to have an unenclosed convenience stair.

The application of 38.3.1.1(1) is restricted by 8.6.9.1(1) to two adjacent levels only. The opening must be separated from other vertical openings serving other floors per 8.6.9.1(2); this requirement prevents the linking of individual openings that would otherwise create a means for spreading the effects of fire among more than two floors. The areas connected by the

opening must be separated from corridors per 8.6.9.1(3). Where the applicable occupancy chapter does not require corridor protection, the spaces containing the convenience opening must be separated from corridors by smoke partitions per 8.6.9.1(5). New convenience openings must be arranged so as to not compromise any required smoke or fire compartmentation per 8.6.9.1(4), as illustrated in Figure A.8.6.9.1(4). The convenience opening is not permitted to be part of the means of egress per 8.6.9.1(6). The space would be required to have access to exits on both levels so occupants would not have to rely on an open stair as part of the required means of egress. One possible application of the 8.6.9.1 convenience opening provisions is shown in Exhibit 8.24.

**Exhibit 8.24**

*Unenclosed two-story stair serving as a convenience opening.*

**8.6.9.2** Where permitted by Chapters 11 through 43, unenclosed vertical openings created by convenience stairways shall comply with all of the following:

- (1) The convenience stair openings shall not serve as required means of egress.
- (2) The building shall be protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7.
- (3)\* The convenience stair openings shall be protected in accordance with the method detailed for the protection of vertical openings in NFPA 13, *Standard for the Installation of Sprinkler Systems*.

Prior to the 2012 edition, the Code permitted only escalator openings to be protected by the draftstop and closely spaced sprinkler criteria specified by NFPA 13, *Standard for the Installation of Sprinkler Systems*, as illustrated by Exhibit 8.25. The provisions of 8.6.9.2 permit the expanded application of this vertical opening protection method to any convenience stair, provided

Exhibit 8.25

Sprinklers around an escalator opening.

that the applicable occupancy chapter permits its use, the stair does not serve as a required means of egress, and the building is protected throughout by an approved, supervised automatic sprinkler system meeting [Section 9.7](#). New for the 2015 edition, for new construction, the opening size is limited to not more than twice the area of the stair, and the number of stories connected by the stair is limited to not more than four (or as otherwise permitted by other sections of the *Code*) in accordance with [8.6.9.2\(4\)](#) and (5), respectively. See the commentary following [8.6.9.7](#) for details on the NFPA 13 sprinkler–draft curtain protection method. Occupancies that permit the use of [8.6.9.2](#) include the following:

1. Assembly occupancies [[12.3.1\(4\)](#), [13.3.1\(4\)](#)]
  2. Mercantile occupancies [[36.3.1\(4\)](#), [37.3.1\(4\)](#)]
  3. Business occupancies [[38.3.1.1\(2\)](#), [39.3.1.1\(2\)](#)]
  4. Industrial occupancies [[40.3.1\(5\)](#)]
  5. Storage occupancies [[42.3.1\(1\)](#)]
- (4) In new construction, the area of the floor opening shall not exceed twice the horizontal projected area of the stairway.
- (5) For new construction, such openings shall not connect more than four contiguous stories, unless otherwise permitted by [Chapters 11 through 43](#).

**A.8.6.9.2(3)** Draftstops protecting vertical openings that are defined in the requirements of NFPA 13, *Standard for the*

*Installation of Sprinkler Systems*, are curtain style descending from the ceiling surface or plane.

**8.6.9.3** Convenience stairs shall be permitted to be unenclosed in large open areas such as atriums and shopping malls.

The provision of [8.6.9.3](#) clarifies that convenience stairs located within large, unprotected vertical openings such as malls and atria, do not require any additional protection beyond what is already required for the large-volume space by the applicable provisions (e.g., [8.6.7](#) for atria).

**8.6.9.4** For other than existing hoistways in existing buildings, elevator cars located within a building shall be enclosed as follows:

- (1) Where there are three or fewer elevator cars in the building, they shall be permitted to be located within the same hoistway enclosure.
- (2) Where there are four elevator cars in the building, they shall be divided in such a manner that not less than two separate hoistway enclosures are provided.
- (3) Where there are more than four elevator cars in the building, the number of elevator cars located within a single hoistway enclosure shall not exceed four.

The requirements addressed by [8.6.9.4](#) help to ensure that smoke and fire in an elevator hoistway will not prevent the use of

all elevators in any building that has 4 or more elevators. If a building has 4 elevators, a maximum of 3 elevators is permitted within the same elevator hoistway or shaft. If the building has more than 4 elevators, not more than 4 elevators can be in one shaft. If smoke and fire prevent the use of the elevators within one hoistway, an elevator in another hoistway might be usable. Because of the maximum limit of 4 elevators per hoistway, a building with 9 to 12 elevators must have a minimum of three hoistways.

The requirements of 8.6.9.4 mesh well with the high-rise building requirements of 11.8.5.2, which apply to standby power. The required standby power system must be connected to at least one elevator serving all floors of the building. Additionally, elevator standby power must be transferable to any elevator. If the hoistway containing the elevator initially powered by the standby power system becomes untenable, the switching requirement will allow for an elevator in a different hoistway to be placed back into service.

**8.6.9.5** Service openings for conveyors, elevators, and dumbwaiters, where required to be open on more than one story at the same time for purposes of operation, shall be provided with closing devices in accordance with 7.2.1.8.

**8.6.9.6** Any escalators and moving walks serving as a required exit in existing buildings shall be enclosed in the same manner as exit stairways. (See 7.1.3.2.)

Where used as an exit, an escalator must be completely enclosed with fire-rated construction, including entrance and discharge doors. It is rare to find an escalator enclosed in such a manner. Escalators located within the required means of egress in existing buildings that maintain compliance with the Code usually make use of one of the provisions of 8.6.9.7 to avoid creating an unprotected vertical opening. By doing so, they are classified as exit access. Note that 7.2.7 prohibits escalators from constituting any part of the required means of egress in new buildings. Thus, in new construction, an escalator can be installed but is not recognized as satisfying the requirements for exit access, exit, or exit discharge.

**8.6.9.7** Any escalators and moving walks not constituting an exit shall have their floor openings enclosed or protected as required for other vertical openings, unless otherwise permitted by one of the following:

- (1) The requirement of 8.6.9.7 shall not apply to escalators in large open areas, such as atriums and enclosed shopping malls.
- (2)\* In existing buildings protected throughout by an approved automatic sprinkler system in accordance with Section 9.7, escalator and moving walk openings shall be permitted to be protected in accordance with the method detailed in NFPA 13, *Standard for the Installation of Sprinkler Systems*, or in accordance with a method approved by the authority having jurisdiction.

- (3) In new buildings protected throughout by an approved automatic sprinkler system in accordance with Section 9.7, escalator and moving walk openings shall be permitted to be protected in accordance with the method detailed in NFPA 13, *Standard for the Installation of Sprinkler Systems*, or in accordance with a method approved by the authority having jurisdiction, and the opening shall not connect more than four contiguous stories unless otherwise permitted by Chapters 11 through 43.
- (4) In buildings protected throughout by an approved automatic sprinkler system in accordance with Section 9.7, escalator and moving walk openings shall be permitted to be protected by rolling steel shutters appropriate for the fire resistance rating of the vertical opening and complying with all of the following:
  - (a) The shutters shall close automatically and independently of each other upon smoke detection and sprinkler operation.
  - (b) A manual means of operating and testing the operation of the shutters shall be provided.
  - (c) The shutters shall be operated not less than once a week to ensure that they remain in proper operating condition.
  - (d) The shutters shall operate at a speed not to exceed 30 ft/min (0.15 m/s) and shall be equipped with a sensitive leading edge.
  - (e) The leading edge shall arrest the progress of a moving shutter and cause it to retract a distance of approximately 6 in. (150 mm) upon the application of a force not exceeding 20 lbf (90 N) applied to the surface of the leading edge.
  - (f) The shutter, following the retraction specified in 8.6.9.7(4)(e), shall continue to close.
  - (g) The operating mechanism for the rolling shutter shall be provided with standby power complying with the provisions of NFPA 70, *National Electrical Code*.

**A.8.6.9.7(2)** The intent is to place a limitation on the size of the opening to which the protection applies. The total floor opening should not exceed twice the projected area of the escalator or moving walk at the floor. Also, the arrangement of the opening is not intended to circumvent the requirements of 8.6.7.

As with any opening through a floor, the openings around the outer perimeter of the escalators should be considered as vertical openings.

The provisions of 8.6.9.7 provide that new escalators (which are not permitted to be part of the means of egress) and existing escalators not serving as exits (see 8.6.9.6) need not be enclosed if certain provisions are met.

The sprinkler-draft curtain method is detailed in NFPA 13, *Standard for the Installation of Sprinkler Systems*. It consists of surrounding the escalator opening, in an otherwise fully sprinklered building, with an 18 in. (455 mm) deep draft stop located on the

underside of the floor to which the escalator ascends. This draft stop serves to delay the heat, smoke, and combustion gases developed in the early stages of a fire on that floor from entering into the escalator well. A row of closely spaced automatic sprinklers located outside of the draft stop also surrounds the escalator well. As sprinklers along this surrounding row are individually activated by heat, their water discharge patterns combine to create a water curtain. A typical installation is shown in [Exhibit 8.25](#). In combination with the sprinkler system in the building, this system should delay fire spread effectively and allow time for evacuation.

Prior editions of the *Code* detailed several methods that permitted the use of unenclosed escalators in completely sprinklered buildings where the escalators were not used as exits. In addition to the sprinkler–draft curtain or rolling shutter methods, the authority having jurisdiction might consider one of the following when evaluating existing buildings:

1. Sprinkler-vent method
2. Spray nozzle method
3. Partial enclosure method

These three methods are detailed in the paragraphs that follow.

**Sprinkler-Vent Method.** Under the conditions specified, escalator or moving walk openings are permitted to be protected by the sprinkler-vent method, which consists of a combination of an automatic fire or smoke detection system, an automatic exhaust system, and an automatic water curtain. This combination of fire protection and system design is required to meet the criteria of paragraphs 1 through 8, which follow, and to be approved by the authority having jurisdiction.

1. The exhaust system should be capable of creating a downdraft through the escalator or moving walk floor opening. The downdraft should have an average velocity of not less than 300 ft/min (1.5 m/s) under normal conditions for a period of not less than 30 minutes. This requirement can be met by providing an air intake from the outside of the building above the floor opening. The test of the system under “normal” conditions requires that the velocity of the downdraft be developed when windows or doors on the several stories normally used for ventilation are open. The size of the exhaust fan and exhaust ducts must be sufficient to meet such ventilation conditions. Experience indicates that fan capacity should be based on a rating of not less than 500 ft<sup>3</sup>/min/ft<sup>2</sup> (8.3 m<sup>3</sup>/s/m<sup>2</sup>) of moving stairway opening to obtain the 300 ft/min (1.5 m/s) velocity required. If the building is provided with an air-conditioning system arranged to be automatically shut down in the event of fire, the test condition should be met with the air-conditioning system shut down. The 300 ft/min (1.5 m/s) downdraft through the opening provides for the testing of the exhaust system without requiring the expansion of air that would be present under actual fire conditions.

2. Operation of the exhaust system for any floor opening should be initiated by an approved device on the involved story and should use one of the following means, in addition to a manual means, for operating and testing the system:

- a. Heat detectors (fixed-temperature, rate-of-rise, or a combination of both)
- b. Waterflow in the sprinkler system
- c. Approved supervised smoke detection located so that the presence of smoke is detected before it enters the stairway

3. Electric power supply to all parts of the exhaust system and its control devices should be designed and installed for maximum reliability. The electric power supply provision of NFPA 20, *Standard for the Installation of Stationary Pumps for Fire Protection*,<sup>41</sup> can be used as a guide to design and installation features that help to ensure maximum reliability.

4. Any fan or duct used in connection with an automatic exhaust system should be of the approved type and should be installed in accordance with the applicable standards in [Chapter 2](#) and [Annex C](#).

5. Periodic tests should be made of the automatic exhaust system, at least quarterly, to maintain the system and the control devices in good working condition.

6. The water curtain should be formed by open sprinklers or by spray nozzles located and spaced to form a complete and continuous barrier along all exposed sides of the floor opening and to reach from the ceiling to the floor. Water discharge for the water curtain should be not less than approximately 3 gal/min/lineal ft (0.6 L/s/lineal m) of water curtain, measured horizontally around the opening.

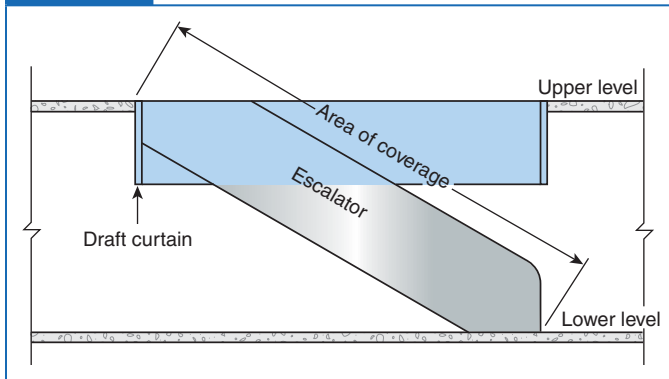

7. The water curtain should operate automatically from thermal-response elements of a fixed-temperature type. These elements should be located with respect to the ceiling/floor opening so that the water curtain actuates upon the advance of heat toward the escalator or moving walk opening.

8. Every automatic exhaust system (including all motors, controls, and automatic water curtain system) should be electrically supervised in an approved manner that is similar to that specified for automatic sprinkler system supervision.

**Spray Nozzle Method.** Under the conditions specified, escalator openings are permitted to be protected by the spray nozzle method, which consists of a combination of an automatic fire or smoke detection system and a system of high-velocity water spray nozzles. This combination of fire protection and system design should meet the criteria of paragraphs 1 through 8, which follow, and be approved by the authority having jurisdiction.

1. Spray nozzles should be of the open type and should have a solid conical spray pattern with discharge angles between 45 degrees and 90 degrees. The number of nozzles, their discharge angles, and their location should be such that the

Exhibit 8.26

Area of coverage for spray nozzle method of protecting escalator openings.

escalator or moving walk opening between the top of the wellway housing and the treadway will be completely filled with dense spray on operation of the system.

2. The number and size of nozzles and water supply should be sufficient to deliver a discharge of 2 gal of water/ft<sup>2</sup>/min (1.4 L of water/m<sup>2</sup>/s) through the wellway, with the area to be figured perpendicularly to the treadway. See Exhibit 8.26.

3. Spray nozzles should be located to take full advantage of the cooling and counterdraft effect. They should be positioned so that the centerline of spray discharge is as closely in line as possible with the slope of the escalator or moving walk, not more than an angle of 30 degrees with the top slope of the wellway housing. Nozzles should also be positioned so that the centerline of discharge is at an angle of not more than 30 degrees from the vertical sides of the wellway housing.

4. Spray nozzles should discharge at a minimum pressure of 25 lb/in.<sup>2</sup> (172 kPa). Water supply piping is permitted to be taken from the sprinkler system, provided that an adequate supply of water is available for the spray nozzles and that the water pressure at the sprinkler farthest from the supply riser is not reduced beyond the required minimum. Water supply taken from the sprinkler system is designed to provide protection from life hazards to the wellway opening during the exit period but is not to be relied on to provide an effective floor cutoff.

5. Control valves should be readily accessible to minimize water damage.

6. A noncombustible or limited-combustible draft curtain should be provided that extends at least 20 in. (510 mm) below and around the opening, and a solid noncombustible wellway housing at least 60 in. (1525 mm) long, measured parallel to the handrail and extending from the top of the handrail enclosure to the soffit of the stairway or ceiling above, should also be provided at each escalator floor opening. Where necessary, spray nozzles should be protected against mechanical damage or tampering that might interfere with proper discharge. See Exhibit 8.27.

Exhibit 8.27

The draft curtain and wellway housing method of protecting vertical openings.

7. The spray nozzle system should operate automatically from thermal-response elements of the fixed-temperature type and be located with respect to the ceiling/floor opening so that the spray nozzle system actuates upon the advance of heat toward the escalator opening. Supervised smoke detection located in or near the escalator opening is permitted to be used to sound an alarm. The spray nozzle system should also be provided with manual means of operation. It is not desirable to have smoke detectors activate the spray nozzles; safeguards against accidental discharge must be provided to prevent both panic and property damage.

8. Control valves for the spray nozzle system and approved smoke detection or thermostatic devices should be electrically supervised in accordance with the applicable provisions of 9.7.2.

**Partial Enclosure Method.** Under the conditions specified, escalator or moving walk openings are permitted to be protected by a partial enclosure, or so-called kiosk, designed to provide an effective barrier to the spread of smoke from floor to floor. This method of fire protection should meet the criteria of paragraphs 1 and 2, which follow, and be approved by the AHJ.

1. Partial enclosure construction should provide fire resistance equivalent to that specified for stairway enclosures in the same building, with openings therein protected by approved, self-closing fire doors. The openings also are permitted to be of approved wired-glass and metal frame construction with wired-glass panel doors.

2. Fire doors are permitted to be equipped with an electric opening mechanism, which opens the door automatically upon the approach of a person. The mechanism should return the door to its closed position upon any interruption of electric current supply, and it should be adjusted so that the pressures generated by a fire will not cause the door to open.

### 8.6.10 Mezzanines.

**8.6.10.1 General.** Multilevel residential housing areas in detention and correctional occupancies in accordance with **Chapters 22** and **23** shall be exempt from the provisions of **8.6.10.2** and **8.6.10.3**.

#### 8.6.10.2 Area Limitations.

**8.6.10.2.1** The aggregate area of mezzanines located within a room, other than those located in special-purpose industrial occupancies, shall not exceed one-third the open area of the room in which the mezzanines are located. Enclosed space shall not be included in a determination of the size of the room in which the mezzanine is located.

**8.6.10.2.2** No limit on the number of mezzanines in a room shall be required.

**8.6.10.2.3** For purposes of determining the allowable mezzanine area, the aggregate area of the mezzanines shall not be included in the area of the room.

**8.6.10.3 Openness.** The openness of mezzanines shall be in accordance with **8.6.10.3.1** or **8.6.10.3.2**.

**8.6.10.3.1** All portions of a mezzanine, other than walls not more than 42 in. (1065 mm) high, columns, and posts, shall be open to and unobstructed from the room in which the mezzanine is located, unless the occupant load of the aggregate area of the enclosed space does not exceed 10.

**8.6.10.3.2** A mezzanine having two or more means of egress shall not be required to open into the room in which it is located if not less than one of the means of egress provides direct access from the enclosed area to an exit at the mezzanine level.

The mezzanine provisions of **8.6.10** were developed for the 1991 edition of the *Code*. They are based on a report prepared by the Board for the Coordination of the Model Codes (BCMC) in an attempt to standardize the treatment of mezzanines among three former U.S. regional building code organizations and NFPA.

The aggregate area of a mezzanine within a room must not exceed one-third the open area (the unenclosed space) of the room in which the mezzanine is located. The area of the mezzanine is not considered to be part of the total open area of the room for the purposes of this calculation. For other purposes, the area of the mezzanine is considered part of the area of the room. Because a mezzanine is limited to such size, it is exempted from being counted as a building story — thus affecting the applicability of *Code* requirements based on the number of building stories or floors.

**Exhibit 8.28** illustrates the use of the one-third area rule for determining whether a level is a mezzanine. A 1000 ft<sup>2</sup> (93 m<sup>2</sup>) partial level is positioned above a 3000 ft<sup>2</sup> (279 m<sup>2</sup>) main room. This is depicted in the plan view at the top of the figure. Because the one-third area rule compares the area of the upper level to the *open* area of the room in which the partial floor level is located, only the unenclosed space of the room is used in the calculation. In **Isometric A** in **Exhibit 8.28**, the space below the

**Exhibit 8.28**

*Determining whether partial upper level meets one-third area rule to qualify as a mezzanine.*

partial floor level is enclosed. The enclosed area beneath the partial upper level is not counted in the area of the main floor. In this case, the area of the upper level is approximately half the area of the open space on the main room below. The size of this area exceeds the one-third allowance, which means that the partial upper level is considered a floor and not a mezzanine. Contrast this arrangement with the arrangement shown in Isometric B in **Exhibit 8.28**. In this case, the space below the partial floor level is open to the main room. The 1000 ft<sup>2</sup> (93 m<sup>2</sup>) area of the partial floor level is compared to the full 3000 ft<sup>2</sup> (279 m<sup>2</sup>) area of the room below. The one-third area rule is met, and the upper level is considered a mezzanine, provided that the other provisions of **8.6.10** are met.

The openness requirements of **8.6.10.3** are intended to provide the mezzanine occupants with a degree of awareness of fire conditions on the floor below that is equivalent to the awareness of the occupants of the fire floor. Because the mezzanine sits above the floor of which it is considered a part, untenable smoke concentrations and the associated loss of visibility due to smoke obscuration might affect the mezzanine level before similarly affecting the floor below. In the same way that openness and awareness are required via the communicating space, or “mini-atrium” provisions of **8.6.6(3)**, the occupants of the mezzanine should be alerted to a fire in any part of the two-level space before the fire becomes a hazard to their safety.

In recognition of such openness, the *Code* treats the mezzanine no differently than an area or room on the level below the mezzanine. If the mezzanine depicted in **Exhibit 8.29** were located in a business occupancy, for example, it would be required to follow the same exit access arrangement rules of any other room on the floor below. Thus, if all occupants could travel across the mezzanine, down the open stair to the room below, and as far across the floor of that room as necessary to reach a point where they had access to two different egress paths, and if that total distance did not exceed the allowable common path of travel [i.e., 75 ft (23 m), or 100 ft (30 m) if sprinklered per **38.2.5.3**, for the new business occupancy in this example], a single exit access from the mezzanine to the floor below would be permitted. If the allowable common path of travel were exceeded, the mezzanine would require a second, remote means of egress.

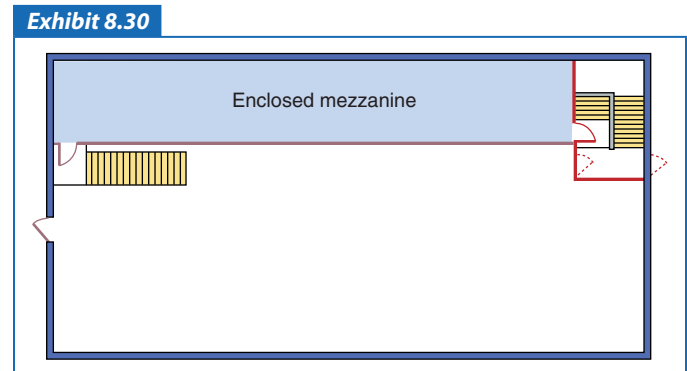

Open mezzanine.

**Paragraph 8.6.10.3.1** recognizes that walls not more than 42 in. (1065 mm) high can serve as guards to prevent falls over the open side of a mezzanine but are low enough to achieve the openness requirement. See **7.2.2.4** for guard requirements.

A limited amount of enclosed space on the mezzanine is also permitted by **8.6.10.3.1** to allow for toilet rooms, limited storage, small offices, and similar areas normally separated from the open area of the mezzanine. In **Exhibit 8.29**, the mezzanine is partially enclosed such that the total occupant load of all enclosed rooms does not exceed 10 persons. This permits a partially enclosed mezzanine to use all the benefits available to a fully open mezzanine.

**Paragraph 8.6.10.3.2** exempts a mezzanine from being open to the room in which it is located if the occupants of the mezzanine are provided with at least two means of egress and if one of those means of egress provides direct access to an exit at the mezzanine level. This provision permits the mezzanine in **Exhibit 8.30** to be enclosed, because one of its two means of egress provides access from the mezzanine directly into an exit stair enclosure that discharges to the outside. Occupants of the mezzanine are then judged as being adequately safe from a fire on the level below because, even if they learn about that fire later than they would have if the mezzanine were open, one of their means of egress does not require them to return through the room below.

Enclosed mezzanine.

## 8.6.11 Concealed Spaces and Draftstops.

**8.6.11.1** Any concealed combustible space in which building materials having a flame spread index greater than Class A are exposed shall be draftstopped as follows:

- (1) Every exterior and interior wall and partition shall be fire-stopped at each floor level, at the top story ceiling level, and at the level of support for roofs.
- (2) Every unoccupied attic space shall be subdivided by draftstops into areas not to exceed 3000 ft<sup>2</sup> (280 m<sup>2</sup>).
- (3) Any concealed space between the ceiling and the floor or roof above shall be draftstopped for the full depth of the space along the line of support for the floor or roof structural members and, if necessary, at other locations to form areas

not to exceed 1000 ft<sup>2</sup> (93 m<sup>2</sup>) for any space between the ceiling and floor, and 3000 ft<sup>2</sup> (280 m<sup>2</sup>) for any space between the ceiling and roof.

**8.6.11.2** The requirements of **8.6.11.1** shall not apply where any of the following conditions are met:

- (1) Where the space is protected throughout by an approved automatic sprinkler system in accordance with **Section 9.7**
- (2)\* Where concealed spaces serve as plenums
- (3) Where the installation is an existing installation

**A.8.6.11.2(2)** See NFPA 90A, *Standard for the Installation of Air-Conditioning and Ventilating Systems*.

**8.6.11.3\*** Draftstopping materials shall be not less than ½ in. (13 mm) thick gypsum board, 1<sup>5</sup>/<sub>32</sub> in. (12 mm) thick wood structural panel, or other approved materials that are adequately supported.

**A.8.6.11.3** A wood structural panel is a panel manufactured from veneers, or wood strands or wafer, or a combination of veneer and wood strands or wafers bonded together with waterproof synthetic resins or other suitable bonding systems, including composite panels, oriented strand board, and plywood.

**8.6.11.4** The integrity of all draftstops shall be maintained.

The vertical spread of fire through shafts, chases, and hollow wall construction and the horizontal spread of fire through plenums and open attics are phenomena common to many serious fires. Where such spaces are protected with automatic sprinklers, the risk of unseen fires is minimized. Certain additional precautions are required where automatic sprinkler protection is not installed in new buildings, and where the materials used have a flame spread index of greater than 25 (i.e., other than Class A interior finish).

Draftstopping of attic spaces is particularly important in shopping centers composed of one story and an attic and in two-story apartment buildings or row houses. Experience has shown that fire starting in one of these occupancy units frequently breaks into the attic space, spreads through the attic, and travels down into adjoining units.

Numerous fires in garden-type apartments have demonstrated two common weaknesses that relate to the lack of adequate firestopping and draftstopping. The following two areas are frequently not firestopped:

1. Between the underside of the roof deck and the top of fire barriers that do not extend through the roofline
2. Inside the pipe chase that contains the plumbing vent stack

The vent stack is of particular concern, because it frequently is located between two mirror-image apartment units and interconnects all the floors of the apartment building. A fire that travels into this concealed space can spread to the attic and soon involve the entire structure.

The term *draft stop* is defined in **3.3.65** as “a continuous membrane used to subdivide a concealed space to resist the passage of smoke and heat.”

**8.6.11.5** In existing buildings, firestopping and draftstopping shall be provided as required by **Chapters 11** through **43**.

An example of an occupancy chapter requirement for firestopping is found in **19.1.6.7**, which requires firestopping between the basement and first floor in existing health care occupancies.

## 8.7 Special Hazard Protection

### 8.7.1 General.

**8.7.1.1\*** Protection from any area having a degree of hazard greater than that normal to the general occupancy of the building or structure shall be provided by one of the following means:

- (1) Enclosing the area with a fire barrier without windows that has a 1-hour fire resistance rating in accordance with **Section 8.3**
- (2) Protecting the area with automatic extinguishing systems in accordance with **Section 9.7**
- (3) Applying both **8.7.1.1(1)** and (2) where the hazard is severe or where otherwise specified by **Chapters 11** through **43**

**A.8.7.1.1** Areas requiring special hazard protection include, but are not limited to, areas such as those used for storage of combustibles or flammables, areas housing heat-producing appliances, or areas used for maintenance purposes.

The effects of fire originating in hazardous areas are minimized by isolating those areas that have a high potential for fire or a high fuel load in accordance with **8.7.1.1**. The occupancy chapters identify the particular hazards against which protection is to be provided and generally address them in the \_\_\_\_3.2 subsection of each occupancy chapter. For example, see **Table 22.3.2.1**, which is applicable to hazardous areas in new detention and correctional occupancies. **Section 8.7** addresses the fundamental fire protection concept of either protecting against known hazards via automatic extinguishment systems or isolating known hazards by means of fire-resistance rated construction. The authority having jurisdiction is responsible for determining the criteria that define a hazardous area.

**8.7.1.2** In new construction, where protection is provided with automatic extinguishing systems without fire-resistive separation, the space protected shall be enclosed with smoke partitions in accordance with **Section 8.4**, unless otherwise permitted by one of the following conditions:

- (1) Where mercantile occupancy general storage areas and stockrooms are protected by automatic sprinklers in accordance with **Section 9.7**

- (2) Where hazardous areas in industrial occupancies are protected by automatic extinguishing systems in accordance with 40.3.2
- (3) Where hazardous areas in detention and correctional occupancies are protected by automatic sprinklers in accordance with 22.3.2

The provisions of 8.7.1.2 require a smoke-resisting enclosure, which includes both surrounding wall barriers and opening protectives such as self-closing doors, where the allowance of 8.7.1.1(2) is used, to protect the hazardous area with automatic sprinklers in lieu of a fire barrier enclosure. The smoke-resisting enclosure, although it lacks a mandated fire resistance rating, will help to contain the smoke generated prior to sprinkler activation and subsequent to fire control. This concept is illustrated in Exhibit 8.31. Paragraph 8.7.1.2(1) permits omission of the additional smoke-resisting enclosure or separation for general storage areas in mercantile occupancies that are protected by automatic sprinklers. For example, in a shoe store, a sprinklered shoe storage area could be left open to the sales area. The clerk might go behind a partial-height partition without going through a door opening to get shoes. Another example is a department store, which usually positions its general storage rooms behind floor-to-ceiling wall barriers at the rear of the store along exterior walls. In this case, double-acting doors (i.e., those that can swing both into and out of the storage room) that might not adequately resist the passage of smoke as required by 8.7.1.2 could be used if the storage area were sprinklered.

The provision of 8.7.1.2(2) exempts hazardous areas in industrial occupancies from the additional smoke-resisting enclosure requirement if those areas are protected by automatic extinguishing systems. The nonhazardous areas might not be sprinklered, but the protected hazardous areas can be left open to the nonhazardous areas.

Sprinkler-protected hazardous contents area.

**8.7.1.3** Doors in barriers required to have a fire resistance rating shall have a minimum ¾-hour fire protection rating and shall be self-closing or automatic-closing in accordance with 7.2.1.8.

**8.7.2\* Explosion Protection.** Where hazardous processes or storage is of such a character as to introduce an explosion potential, an explosion venting system or an explosion suppression system specifically designed for the hazard involved shall be provided.

**A.8.7.2** For details, see NFPA 68, *Standard on Explosion Protection by Deflagration Venting*.

If a potential hazard is of an explosive nature, explosion venting or an explosion suppression system is required. NFPA 68, *Standard on Explosion Protection by Deflagration Venting*,<sup>42</sup> contains details of acceptable venting systems; NFPA 69, *Standard on Explosion Prevention Systems*,<sup>43</sup> covers suppression systems. NFPA 654, *Standard for the Prevention of Fire and Dust Explosions from the Manufacturing, Processing, and Handling of Combustible Particulate Solids*,<sup>44</sup> is useful where explosive dusts are encountered.

### 8.7.3 Flammable Liquids and Gases.

**8.7.3.1** The storage and handling of flammable liquids or gases shall be in accordance with the following applicable standards:

- (1) NFPA 30, *Flammable and Combustible Liquids Code*
- (2) NFPA 54, *National Fuel Gas Code*
- (3) NFPA 58, *Liquefied Petroleum Gas Code*

**8.7.3.2\*** No storage or handling of flammable liquids or gases shall be permitted in any location where such storage would jeopardize egress from the structure, unless otherwise permitted by 8.7.3.1.

**A.8.7.3.2** NFPA 58, *Liquefied Petroleum Gas Code*, permits portable butane-fueled appliances in restaurants and in attended commercial food catering operations where fueled by not in excess of two 10 oz (0.28 kg) LP-Gas capacity, nonrefillable butane containers having a water capacity not in excess of 1.08 lb (0.4 kg) per container. Containers are required to be directly connected to the appliance, and manifolding of containers is not permitted. Storage of cylinders is also limited to 24 containers, with an additional 24 permitted where protected by a 2-hour fire resistance-rated barrier.

**8.7.3.3\* Alcohol-Based Hand-Rub Dispensers.** Where permitted by Chapters 11 through 43, alcohol-based hand-rub dispensers shall be permitted provided they meet all of the following criteria:

- (1) The maximum individual dispenser fluid capacity shall be as follows:
  - (a) 0.32 gal (1.2 L) for dispensers in corridors and areas open to corridors
  - (b) 0.53 gal (2.0 L) for dispensers in rooms or suites of rooms separated from corridors

- (2) Where aerosol containers are used, the maximum capacity of the aerosol dispenser shall be 18 oz. (0.51 kg) and shall be limited to Level 1 aerosols as defined in NFPA 30B, *Code for the Manufacture and Storage of Aerosol Products*.
- (3) Dispensers shall be separated from each other by horizontal spacing of not less than 48 in. (1220 mm).
- (4) Not more than an aggregate 10 gal (37.8 L) of alcohol-based hand-rub solution or 1135 oz (32.2 kg) of Level 1 aerosols, or a combination of liquids and Level 1 aerosols not to exceed, in total, the equivalent of 10 gal (37.8 L) or 1135 oz (32.2 kg,) shall be in use outside of a storage cabinet in a single smoke compartment or fire compartment or story, whichever is less in area. One dispenser complying with 8.7.3.3 (1) per room and located in that room shall not be included in the aggregated quantity.
- (5) Storage of quantities greater than 5 gal (18.9 L) in a single smoke compartment or fire compartment or story, whichever is less in area, shall meet the requirements of NFPA 30, *Flammable and Combustible Liquids Code*.
- (6) Dispensers shall not be installed in the following locations:
  - (a) Above an ignition source for a horizontal distance of 1 in. (25 mm) to each side of the ignition source
  - (b) To the side of an ignition source within a 1 in. (25 mm) horizontal distance from the ignition source
  - (c) Beneath an ignition source within a 1 in. (25 mm) vertical distance from the ignition source
- (7) Dispensers installed directly over carpeted floors shall be permitted only in sprinklered areas of the building.
- (8) The alcohol-based hand-rub solution shall not exceed 95 percent alcohol content by volume.
- (9) Operation of the dispenser shall comply with the following criteria:
  - (a) The dispenser shall not release its contents except when the dispenser is activated, either manually or automatically by touch-free activation.
  - (b) Any activation of the dispenser shall only occur when an object is placed within 4 in. (100 mm) of the sensing device.
  - (c) An object placed within the activation zone and left in place shall not cause more than one activation.
  - (d) The dispenser shall not dispense more solution than the amount required for hand hygiene consistent with label instructions.
  - (e) The dispenser shall be designed, constructed, and operated in a manner that ensures accidental or malicious activation of the dispensing device is minimized.
  - (f) The dispenser shall be tested in accordance with the manufacturer's care and use instructions each time a new refill is installed.

**A.8.7.3.3** The total quantities of flammable liquids in any area should comply with the provisions of other recognized codes, including NFPA 1, *Fire Code*, and NFPA 30, *Flammable and*

*Combustible Liquids Code*. In addition, special consideration should be given to the following:

- (1) Obstructions created by the installation of hand-rub solution dispensers
- (2) Location of dispensers with regard to adjacent combustible materials and potential sources of ignition, especially where dispensers are mounted on walls of combustible construction
- (3) Requirements for other fire protection features, including complete automatic sprinkler protection, to be installed throughout the compartment
- (4) Amount and location of the flammable solutions, both in use and in storage, particularly with respect to potential for leakage or failure of the dispenser

Provisions for alcohol-based hand rub (ABHR) dispensers first appeared in the 2006 edition of the *Code* in **Chapters 18 and 19** (new and existing health care occupancies), and **Chapters 20 and 21** (new and existing ambulatory health care occupancies) — see **Exhibit 8.32** for an example of an ABHR dispenser. The addition of these criteria recognized the needs of the health care industry to provide ABHR dispensers in its facilities to prevent the spread of infectious diseases without compromising life safety from fire. In the last decade, the prevalence of ABHR dispensers in nearly all occupancies has grown substantially. ABHR dispensers can be found in occupancies such as office buildings, grocery stores, shopping malls, schools, hotels, and restaurants, just to name a few. Following the publication of the 2006 edition

**Exhibit 8.32**

*Alcohol-based hand rub (ABHR) dispenser.*

of the *Code*, additional occupancy technical committees, such as the Technical Committee on Educational and Day Care Occupancies, developed ABHR dispenser criteria for the occupancies for which it is responsible. Recognizing the emerging trend of increasing ABHR dispenser use in many different occupancies, it was determined that ABHR dispenser requirements should reside in a core chapter to which the occupancy chapters could reference, rather than each occupancy chapter prescribing its own requirements.

The requirements for ABHR dispensers in 8.7.3.3 are new for the 2015 edition of the *Code*, although they are based on, but not identical to, the criteria that have been contained in Chapters 18 through 21 for health care and ambulatory health care occupancies. They are formatted as a “where permitted” provision, such that 8.7.3.3 applies only where specifically referenced by another section of the *Code*. Occupancies in which the use of ABHR dispensers in accordance with 8.7.3.3 are permitted include the following:

1. Assembly occupancies (12.4.5, 13.4.5)
2. Detention and correctional occupancies (22.4.6, 23.4.6)
3. Lodging or rooming houses (26.3.2)
4. Hotels and dormitories (28.4.2, 29.4.2)
5. Apartment buildings (30.4.2, 31.4.2)
6. Residential board and care occupancies (32.2.4, 32.3.4.2, 33.2.4, 33.3.4.2)
7. Mercantile occupancies (36.4.6, 37.4.6)
8. Business occupancies (38.4.4, 39.4.4)
9. Industrial occupancies (40.4.3)
10. Storage occupancies (42.4.3)

Occupancies in which ABHR dispensers are permitted, but regulated separately by the applicable occupancy chapter and not by 8.7.3.3, include the following:

1. Educational occupancies (14.4.4, 15.4.4)
2. Day care occupancies (16.4.4, 17.4.4)
3. Health care occupancies (18.4.3, 19.4.3)
4. Ambulatory health care occupancies (20.4.3, 21.4.3).

### 8.7.4 Laboratories.

**8.7.4.1** Laboratories that use chemicals shall comply with NFPA 45, *Standard on Fire Protection for Laboratories Using Chemicals*, unless otherwise modified by other provisions of this *Code*.

**8.7.4.2** Laboratories in health care occupancies and medical and dental offices shall comply with NFPA 99, *Health Care Facilities Code*.

**8.7.5\* Hyperbaric Facilities.** All occupancies containing hyperbaric facilities shall comply with NFPA 99, *Health Care Facilities Code*, Chapter 20, unless otherwise modified by other provisions of this *Code*.

**A.8.7.5** While the scope of NFPA 99, *Health Care Facilities Code*, is limited to health care occupancies, it is the intent that

this requirement be applied to hyperbaric facilities used in all occupancies.

Hyperbaric facilities can be found in a variety of occupancies in addition to health care occupancies. For example, hyperbaric chambers have been installed in amusement centers and physical fitness centers and have been promoted as health-enhancing aids. Paragraph 8.7.5 extends the use of the provisions of NFPA 99, *Health Care Facilities Code*,<sup>45</sup> to hyperbaric facilities, regardless of occupancy classification.

## 8.8\* Inspection and Testing of Door Assemblies

Doors, other than those listed in 8.2.2.4 and 8.3.3.13, that are required to be self-closing or automatic closing shall comply with all of the following:

- (1) Door assemblies shall be inspected annually.
- (2) Doors shall be operated to confirm full closure.
- (3) Parts found to be damaged or inoperative shall be replaced.
- (4) Door openings and the surrounding areas shall be kept clear of anything that could obstruct or interfere with the free operation of the door.
- (5) Blocking or wedging of doors in the open position shall be prohibited.
- (6) Self-closing and automatic closing devices shall be kept in working condition at all times.

**A.8.8** Doors covered by this section include smoke barrier doors, doors in smoke partitions, and doors serving hazardous areas. Paragraph 7.2.1.15 addresses inspection and testing of means of egress doors. Paragraph 8.2.2.4 addresses maintenance of doors required to be smoke leakage. Paragraph 8.3.3.13 addresses the the inspection and testing of fire doors.

Section 8.8, which is new for the 2015 edition of the *Code*, prescribes minimum inspection and maintenance requirements for doors that are required to be self-closing or automatic closing — typically doors in smoke partitions, smoke barriers, and fire barriers — to ensure that they will perform as intended and protect the opening in which they are installed under fire conditions. The criteria contained in Section 8.8 are based on requirements for smoke door assemblies found in NFPA 105, *Standard for Smoke Door Assemblies and Other Opening Protectives*. Although not mandated by Section 8.8, it might be prudent to document the required annual inspection, and maintain records as part of a comprehensive inspection program, to allow the documentation to be reviewed by the authority having jurisdiction upon request.

# Building Service and Fire Protection Equipment

As the title indicates, **Chapter 9** divides the types of equipment commonly found in buildings into two categories: building service and fire protection. For the most part, the requirements for building service equipment are handled by direct reference to another code or standard, with little or no modification or additional requirements in the occupancy chapters. The result is that compliance with the referenced document is required in order for the building to achieve overall compliance with the *Life Safety Code*. Fire protection systems, particularly fire alarm and automatic sprinkler systems, are handled quite differently. For these systems, the *Code* presents a menu of general provisions that are used in conjunction with the installation standards. To apply these provisions, a specific requirement from another section of the *Code* must require their use. For example, **9.6.2.1** addresses fire alarm system signal initiation and **12.3.4.2** mandates the use of those provisions for fire alarm systems in new assembly occupancies.

The features that maintain a building safe from fire are varied and work in combination to provide protection for the occupants under a range of potentially adverse conditions. This chapter addresses those systems that help either to maintain a safe environment or to keep the occupants safe from the effects of a fire.

**Section 9.6** identifies types of fire alarm initiating and notification systems. The fire alarm system plays an important role in notifying the building occupants of a fire, as well as in summoning help from outside sources, such as the fire department.

**Section 9.7** applies to automatic sprinkler systems, which provide an active method for controlling the effects of a fire. **Section 9.8** addresses alternative automatic extinguishing systems, such as those that might be used where the application of water from a sprinkler system is undesirable because of the incompatibility of water with the protected contents (such as some combustible metals). Manual fire extinguishing features, such as portable fire extinguishers and standpipe systems, are addressed by **Sections 9.9** and **9.10**, respectively.

**Section 9.12** provides a reference to NFPA 720, *Standard for the Installation of Carbon Monoxide (CO) Detection and Warning Equipment*,<sup>1</sup> for the installation of such equipment where required by other sections of the *Code*. **Section 9.13** addresses special inspections and tests of fire protection systems, such as those required for smoke control systems in **9.3.3**.

Note that the occupancy chapters mandate the type of system required and the conditions under which that system is required.

## 9.1 Utilities

**9.1.1 Gas.** Equipment using gas and related gas piping shall be in accordance with NFPA 54, *National Fuel Gas Code*, or NFPA 58, *Liquefied Petroleum Gas Code*, unless such installations are approved existing installations, which shall be permitted to be continued in service.

Although the referenced documents do not specify whether gas piping is permitted to pass through an exit enclosure, such as an enclosed stair, other provisions of the *Life Safety Code* apply. For example, see the provisions of **7.1.3.2.1**(9) and (10) and the commentary following **7.1.3.2.1**(12). These provisions stress that the only openings permitted in the enclosure walls between an exit and other building spaces are those needed to provide access into the exit from any normally occupied space and those needed to provide access out of the exit at the level of exit discharge. In other words, only those openings used by an occupant to enter and leave the exit enclosure are permitted. Gas piping is not permitted to pass through exit enclosure walls. Conversely, the *Code* does not prohibit the installation of gas piping in elevator shafts, dumbwaiters, or chutes. However, these areas are clearly prohibited from containing gas piping by NFPA 54, *National Fuel Gas Code*.<sup>2</sup> Thus, the *Code* and the reference document are used together to address installation safety and life safety.

**9.1.2 Electrical Systems.** Electrical wiring and equipment shall be in accordance with NFPA 70, *National Electrical Code*, unless such installations are approved existing installations, which shall be permitted to be continued in service.

Because electrical wiring might require a complicated system or array involving many specifications and design details, the *Code* does not repeat them; rather, it references NFPA 70®, *National Electrical Code*®,<sup>3</sup> for design and installation requirements.

The *Life Safety Code* requirements for emergency lighting addressed by **Section 7.9** and, in particular, by **7.9.2.3**, with respect to independence of the emergency lighting source and distribution network, are more stringent than the more general requirements of NFPA 70. See the commentary throughout **Section 7.9**.

**9.1.3 Emergency Generators and Standby Power Systems.** Where required for compliance with this *Code*, emergency generators and standby power systems shall comply with **9.1.3.1** and **9.1.3.2**.

**9.1.3.1** Emergency generators and standby power systems shall be installed, tested, and maintained in accordance with NFPA 110, *Standard for Emergency and Standby Power Systems*.

**9.1.3.2** New generator controllers shall be monitored by the fire alarm system, where provided, or at an attended location, for the following conditions:

- (1) Generator running
- (2) Generator fault
- (3) Generator switch in nonautomatic position

**9.1.4 Stored Electrical Energy Systems.** Stored electrical energy systems shall be installed, tested, and maintained in accordance with NFPA 111, *Standard on Stored Electrical Energy Emergency and Standby Power Systems*.

## 9.2 Heating, Ventilating, and Air-Conditioning

**9.2.1 Air-Conditioning, Heating, Ventilating Ductwork, and Related Equipment.** Air-conditioning, heating, ventilating ductwork, and related equipment shall be in accordance with NFPA 90A, *Standard for the Installation of Air-Conditioning and Ventilating Systems*, or NFPA 90B, *Standard for the Installation of Warm Air Heating and Air-Conditioning Systems*, as applicable, unless such installations are approved existing installations, which shall be permitted to be continued in service.

For the proper installation of HVAC systems, 9.2.1 refers the Code user to NFPA 90A, *Standard for the Installation of Air-Conditioning and Ventilating Systems*.<sup>4</sup> For occupancies with small overall volumes, such as one- and two-family dwellings, the Code refers the user to NFPA 90B, *Standard for the Installation of Warm Air Heating and Air-Conditioning Systems*.<sup>5</sup>

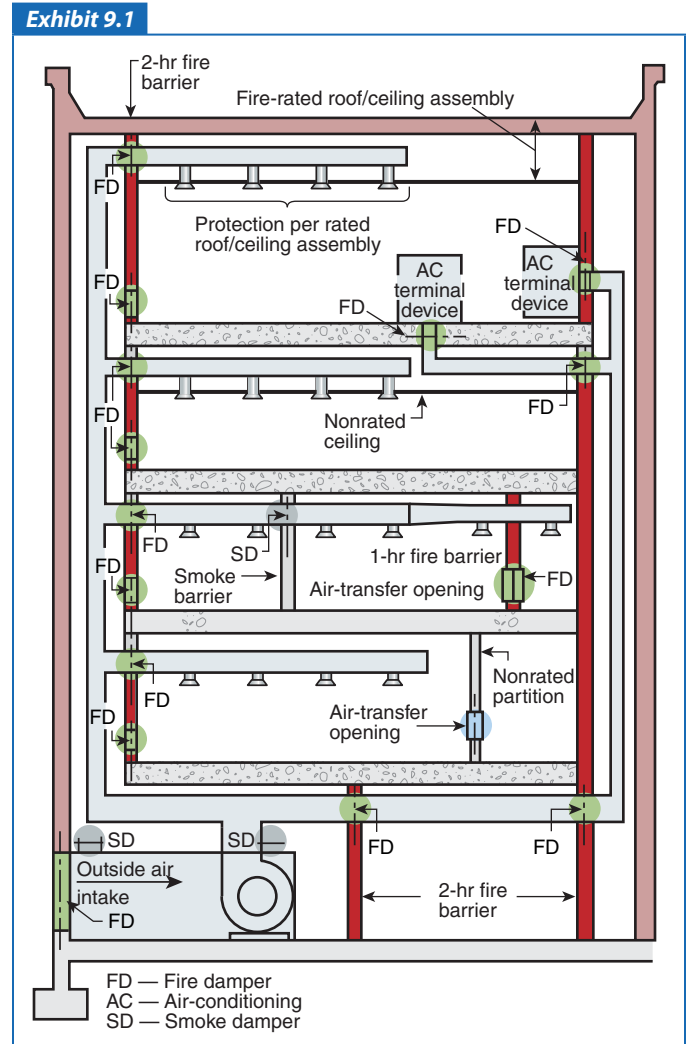

For example, NFPA 90A addresses fire damper requirements for both ductwork and air-transfer grilles that penetrate fire barriers. NFPA 90A also prohibits means of egress corridors in health care, detention and correctional, and residential occupancies from being used as a portion of a supply-, return-, or exhaust-air system serving adjoining areas. Exhibit 9.1 identifies some of the areas where fire dampers and smoke dampers would be required by NFPA 90A.

**9.2.2 Ventilating or Heat-Producing Equipment.** Ventilating or heat-producing equipment shall be in accordance with NFPA 91, *Standard for Exhaust Systems for Air Conveying of Vapors, Gases, Mists, and Noncombustible Particulate Solids*; NFPA 211, *Standard for Chimneys, Fireplaces, Vents, and Solid Fuel-Burning Appliances*; NFPA 31, *Standard for the Installation of Oil-Burning Equipment*; NFPA 54, *National Fuel Gas Code*; or NFPA 70, *National Electrical Code*, as applicable, unless such installations are approved existing installations, which shall be permitted to be continued in service.

**9.2.3 Commercial Cooking Operations.** Where required by another section of this Code, commercial cooking operations shall be protected in accordance with NFPA 96, *Standard for Ventilation Control and Fire Protection of Commercial Cooking Operations*, unless such installations are approved existing installations, which shall be permitted to be continued in service.

The occupancy chapters that address the protection of commercial cooking operations do so in the provisions for the protection of hazards. To understand the intent of the Code, close attention must be paid to the manner in which the protection is addressed.

For example, for health care occupancies, 18.3.2.5.2 states that residential cooking equipment used for food warming or limited cooking is not required to be protected; nor must the space be segregated from the rest of the building. For day-care occupancies, a similar provision appears in 16.3.2.5; however, this provision requires the approval of the authority having jurisdiction (AHJ) to exempt protection and segregation of domestic

Partition and fire barrier penetration protection.

cooking equipment (the term *approved* is defined in 3.2.1 as “acceptable to the authority having jurisdiction”). Paragraphs 12.3.2.2 and 13.3.2.2, which apply to assembly occupancies, and 22.3.2.4 and 23.3.2.4, which apply to detention and correctional occupancies, permit a kitchen to be open to the rest of a building only if the cooking equipment is protected in accordance with 9.2.3.

In occupancy chapters that do not refer to the protection of cooking equipment, NFPA 96, *Standard for Ventilation Control and Fire Protection of Commercial Cooking Operations*,<sup>6</sup> needs to be consulted to determine the criteria that define commercial cooking operations and their appropriate required protection.

**9.2.4 Ventilating Systems in Laboratories Using Chemicals.** Ventilating systems in laboratories using chemicals shall be in accordance with NFPA 45, *Standard on Fire Protection for Laboratories Using Chemicals*.

NFPA 45, *Standard on Fire Protection for Laboratories Using Chemicals*,<sup>7</sup> contains requirements for construction, ventilation, and fire protection in laboratory buildings, as well as for units and work areas in all buildings. Additional requirements for laboratories in health care occupancies were previously found in NFPA 99, *Health Care Facilities Code*.<sup>8</sup> NFPA 99 now mandates compliance with NFPA 45 for laboratories in health care facilities.

## 9.3 Smoke Control

**9.3.1 Installation.** Where required by another section of this *Code*, smoke control systems shall be designed, installed, inspected, tested, and maintained in accordance with NFPA 92, *Standard for Smoke Control Systems*; NFPA 204, *Standard for Smoke and Heat Venting*; or nationally recognized standards, engineering guides, or recommended practices, as approved by the authority having jurisdiction.

The provision of 9.3.1 does not itself require smoke control systems; it mandates that, if such systems are installed for *Code* compliance, they must be designed, installed, inspected, tested, and maintained in accordance with NFPA 92, *Standard for Smoke Control Systems*,<sup>9</sup> or NFPA 204, *Standard for Smoke and Heat Venting*,<sup>10</sup> as applicable.

NFPA 92 addresses smoke control systems that use barriers, airflows, and pressure differences to confine the smoke of a fire to the zone of fire origin and, thus, maintain a tenable environment in other zones. The requirements of NFPA 92 can be used to create a smokeproof enclosure using the stair pressurization method described in 7.2.3.9. The standard also covers smoke control for elevator hoistways by employing the following methods, either singly or in combination:

1. Fire floor exhaust
2. Elevator lobby pressurization

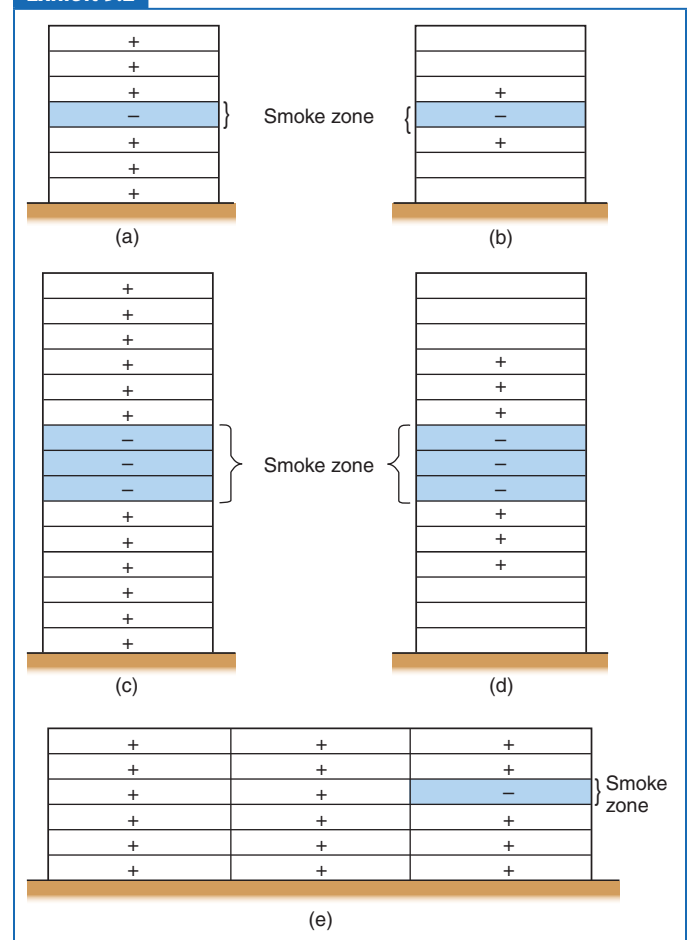

### 3. Smoketight elevator lobby construction

### 4. Elevator hoistway pressurization

NFPA 92 also addresses, in detail, zoned smoke control under which a building can be divided into a number of smoke control zones. Each zone is separated from the others by partitions, floors, and doors that can be closed to inhibit the movement of smoke. A smoke control zone can consist of one or more floors, or a floor can consist of more than one smoke control zone. Some arrangements of smoke control zones are depicted in Exhibit 9.2. The smoke zones are indicated by minus signs — negative pressurization or exhaust — and positively pressurized spaces are indicated by plus signs. All nonsmoke zones might be pressurized, as in Part (a) and Part (c), or only those nonsmoke zones that are adjacent to the smoke zone might be pressurized, as in Part (b) and Part (d). In Part (e), the smoke zone has been limited to a portion of a floor.

The subject of maintaining tenable conditions within large zones of fire origin (such as atria and shopping malls) is also addressed by NFPA 92, which provides technical data relevant to the design, installation, testing, operation, and maintenance of

**Exhibit 9.2**

Smoke control zone arrangement.

smoke management systems in buildings with large-volume spaces. These systems manage smoke within the space where the fire exists or between spaces not separated by smoke barriers. The requirements of NFPA 92 can be used to implement smoke management systems that help to maintain a tenable environment in the means of egress from large-volume building spaces during the time required for evacuation. The standard also addresses the control and reduction of the smoke migration between the fire area and adjacent spaces. The commentary following A.8.6.7(6) on atrium smoke control draws extensively from the theories and protection strategies presented in NFPA 92. In the example cited in the commentary following A.8.6.7(6), a volumetric exhaust rate,  $V$ , was calculated following a detailed analysis of the physics associated with fire growth and smoke generation. This analysis concerns a particular atrium building configuration in which the exhaust rate keeps smoke from descending from the ceiling level to a level lower than the head height of persons on the highest floor of the building open to the atrium. The summation of the exercise is detailed in Exhibit 8.22 and is generalized in Exhibit 9.3.

Exhibit 9.3

Control of smoke layer.

An approved maintenance and testing program must be provided to ensure the operational integrity of smoke control systems. A combination public address system and emergency occupant notification system is used routinely, and any problems with the system will be readily apparent; conversely, a smoke control system dedicated to emergency use only is not subject to daily use. Therefore, maintenance and testing of smoke control systems are necessary.

**9.3.2 System Design.** The engineer of record shall clearly identify the intent of the system, the design method used, the appropriateness of that method, and the required means of inspecting, testing, and maintaining the system.

**9.3.3 Acceptance Testing.** Acceptance testing shall be performed by a special inspector in accordance with Section 9.13.

### 9.3.4 Smoke Control System Operation.

**9.3.4.1** Floor- or zone-dependent smoke control systems shall be automatically activated by sprinkler waterflow or smoke detection systems.

**9.3.4.2** Means for manual operation of smoke control systems shall be provided at an approved location.

## 9.4 Elevators, Escalators, and Conveyors

**9.4.1\* General.** An elevator, other than an elevator in accordance with 7.2.13, shall not be considered a component in a required means of egress but shall be permitted as a component in an accessible means of egress.

**A.9.4.1** Under certain conditions, elevators are recognized as means of egress.

The use of elevators for emergency evacuation purposes, where operated by trained emergency service personnel (e.g., building personnel, fire personnel), should be incorporated into the building evacuation program. Elevators are normally capable of manual, in-car fire fighter operation (Phase II) after elevator recall (Phase I). In addition, there usually are two or more shafts wherever there are more than three elevators, which further enhances the possibilities for elevator use during an emergency evacuation where operated by trained personnel.

In high-rise buildings, in towers, or in deep underground spaces where travel over considerable vertical distance on stairs can cause persons incapable of such physical effort to collapse before they reach the street exit, stairways are permitted to be used for initial escape from the immediate area of danger, and elevators are permitted to be used to complete the travel to the street.

It can be reasonably assumed that, in all buildings of sufficient height to indicate the need for elevators, elevators will be provided for normal use; for this reason, no requirements for mandatory installation of elevators are included in the Code.

For additional information on elevators, see ASME A17.1/CSA B44, *Safety Code for Elevators and Escalators*, and ASME A17.3, *Safety Code for Existing Elevators and Escalators*.

In much earlier Code editions, the egress capacity of elevators was calculated based on the assumption that three average elevators were roughly equivalent to the formerly used single unit of stairway exit width. Because of this assumption, elevators were accepted as required egress components under certain limited conditions. No such credit has been given since 1956 because of some inherent characteristics that might make elevators unsuitable for emergency exit use. These characteristics are accentuated in modern automatic elevators where no operator

is available to exercise judgment in the control of the elevator in case of fire or other emergency. The reasons that elevators are not credited as part of the required means of egress are summarized in paragraphs 1 through 4, which follow.

1. People seeking to escape from a fire by using an elevator might have to wait at the elevator door for some time; during that time, they might be exposed to fire or smoke, or they might panic.

2. Automatic elevators travel to floors by responding to call buttons, both in the elevator car and in elevator lobbies. Because this operation cannot be canceled once a button is pressed, it is possible for an elevator descending from floors above a fire to stop automatically at the floor of the fire. The doors will open automatically, thus exposing occupants to fire and smoke.

A further consideration is that an elevator shaft might act as a “chimney” in a multistory building. Unless positively pressurized with respect to the fire floor, the shaft can carry heat and smoke from a fire and expose passengers to hazardous levels of both — even if the elevator does not stop at the fire floor and continues to function. An elevator moving within its shaft enclosure might act as a piston within a cylinder and push or pull the smoke and fire gases to floors not initially exposed to combustion products.

3. Modern elevators will not operate until the doors are fully closed. In an emergency, a large number of people might try to crowd into an elevator, preventing the doors from closing and preventing the elevator from operating.

4. Power failure might render the elevators inoperative or might cause people to become trapped in elevators stopped between floors. Under fire conditions, sufficient time to rescue the trapped occupants through emergency escape hatches or doors may not be available.

**Exhibit 9.4** is an example of an elevator corridor call station pictograph, as required by 9.4.2.4 for new elevators, used to notify occupants that an elevator is unsuitable for emergency egress use.

Recognizing the viability of elevators to facilitate the movement of people, the *Code* has, in recent editions, added guidelines addressing their use in limited circumstances. The four circumstances under which an elevator can be part of a building’s evacuation plan are described in paragraphs 1 through 4, which follow.

1. An elevator might be used for assisting in a staged evacuation, such as might be desirable in a high-rise building. Though it cannot be used as a component of the means of egress, an elevator can be a useful tool in the evacuation of a tall building, which can involve travel down many flights of stairs by occupants having varying capabilities of using stairs due to age, illness, or other physical limitations. Details on the use of elevators for occupant-controlled evacuation prior to Phase I Emergency Recall Operations are provided in **Section 7.14**. See **Section 7.14**

**Exhibit 9.4**

## In Case Of Fire Elevators Are Out Of Service

*Elevator corridor call station pictograph. (© Payphoto, Dreamstime.com)*

and associated commentary for further details on the use of elevators for occupant evacuation.

2. An elevator can be used as a means of evacuating people from an area of refuge. Elevators are an effective means of transporting people with severe mobility impairments. The criteria for the use of elevators for evacuation from an area of refuge are established in 7.2.12.2.4. Also see the commentary on 7.2.12.

3. In underground assembly occupancies, the *Code* might require an elevator or escalator for the purpose of assisting in an emergency evacuation in an upward direction. An example of the *Code* requiring an elevator to be used under emergency conditions can be found in 12.4.3.3, which requires each level of a new assembly occupancy with a floor level more than 30 ft (9.1 m) below the level of exit discharge to be divided into at least two smoke compartments. Per 12.4.3.3.2, each compartment must be provided with a mechanical means of moving people vertically, such as an elevator or escalator. These

**Exhibit 9.5**

Elevator and escalator use in underground assembly occupancy.

requirements are in addition to those of Section 11.7, which addresses underground and limited access structures. In Exhibit 9.5, an escalator is used in smoke zone A and an elevator is used in smoke zone B to meet the requirements of 12.4.3.3.2.

4. In special types of towers (typically air traffic control towers), the Code recognizes the use of an elevator as a secondary means of egress. See the commentary on 7.2.13.

### 9.4.2 Code Compliance.

For elevator installations, the Code requires compliance with one of the following:

1. ASME A17.1/CSA B44, *Safety Code for Elevators and Escalators*<sup>11</sup>
2. ASME A17.3, *Safety Code for Existing Elevators and Escalators*<sup>12</sup>

The Code additionally requires that a sprinkler system, if installed, meet the requirements of NFPA 13, *Standard for the Installation of Sprinkler Systems*.<sup>13</sup> ASME A17.1/CSA B44 permits sprinklers in elevator hoistways and machine rooms in accordance with NFPA 13, subject to the following provisions:

1. All risers and returns are to be located outside these spaces.
2. Branch lines in the hoistway are to supply only the sprinklers on that level.
3. A means for disconnecting the main line power supply to the affected elevator automatically upon, or prior to, the application of water from sprinklers located in the machine room or hoistway is to be provided as follows:
  - a. The means must be independent of the elevator control and cannot be self-resetting.
  - b. The activation of sprinklers outside the hoistway or machine room is not to disconnect the main line power supply.

- c. Smoke detectors are not to be used to activate sprinklers in these spaces or to disconnect the main line power supply.

ASME A17.1/CSA B44 and ASME A17.3 are also referenced because the Code recognizes the use of elevators and escalators under limited conditions and because fire fighters might need to use elevators during fire suppression operations. Compliance with these documents makes it possible to recall elevators to the ground floor or other designated floor during a fire, thus taking the elevators out of service. The provisions also permit fire fighters to manually override the controls and use the elevators as necessary.

The reference to ASME A17.7/CSA B44.7, *Performance-Based Safety Code for Elevators and Escalators*,<sup>14</sup> provides an alternative method for establishing design and product safety and recognizes that code requirements are not always able to anticipate new technologies and innovation in the elevator industry. Compliance with ASME A17.7/CSA B44.7 is deemed to be equivalent to ASME A17.1/CSA B44 for new elevators and escalators, or ASME A17.3 for existing elevators and escalators.

Where elevators are to be used for occupant evacuation, the Code provides additional requirements — see Section 7.14, Elevators for Occupant-Controlled Evacuation Prior to Phase I Emergency Recall Operations. The requirements of Section 7.14 augment those of ASME A17.1/CSA B44 and Section 9.4 of this Code.

**9.4.2.1** Except as modified herein, new elevators, escalators, dumbwaiters, and moving walks shall be in accordance with the requirements of ASME A17.1/CSA B44, *Safety Code for Elevators and Escalators*.

**9.4.2.2** Except as modified herein, existing elevators, escalators, dumbwaiters, and moving walks shall be in accordance with the requirements of ASME A17.3, *Safety Code for Existing Elevators and Escalators*.

**9.4.2.3** Elevators in accordance with ASME A17.7/CSA B44.7, *Performance-Based Safety Code for Elevators and Escalators*, shall be deemed to comply with ASME A17.1/CSA B44, *Safety Code for Elevators and Escalators*, or ASME A17.3, *Safety Code for Existing Elevators and Escalators*.

**9.4.2.4** For other than elevators used for occupant-controlled evacuation in accordance with Section 7.14 and other than existing elevators, the elevator corridor call station pictograph specified in 2.27.9 of ASME A17.1/CSA B44, *Safety Code for Elevators and Escalators*, shall be provided at each elevator landing.

The elevator corridor call station pictograph depicted in Exhibit 9.4 is mandated for new elevators by 9.4.2.4 unless the elevators are intended to be used for occupant-controlled

evacuation and comply with [Section 7.14](#). In accordance with ASME A17.1/CSA B44, *Safety Code for Elevators and Escalators*, the pictograph must have dimensions of not less than 4.12 in. (100 mm) in width, and 5.62 in. (140 mm) in height, and must state “In Case Of Fire Elevators Are Out Of Service” above the pictograph, and “Use Exit” beneath the pictograph. The standardized pictograph is intended to preclude inconsistency and the resultant potential for confusion.

### 9.4.3 Fire Fighters’ Emergency Operations.

**9.4.3.1** All new elevators shall conform to the fire fighters’ emergency operations requirements of ASME A17.1/CSA B44, *Safety Code for Elevators and Escalators*.

**9.4.3.2** All existing elevators having a travel distance of 25 ft (7620 mm) or more above or below the level that best serves the needs of emergency personnel for fire-fighting or rescue purposes shall conform to the fire fighters’ emergency operations requirements of ASME A17.3, *Safety Code for Existing Elevators and Escalators*.

Because an elevator stopping at a fire floor (intentionally or unintentionally) is an extreme hazard, the *Code* mandates compliance with the fire fighters’ emergency operations requirements of ASME A17.1/CSA B44, *Safety Code for Elevators and Escalators*, and ASME A17.3, *Safety Code for Existing Elevators and Escalators*, for

new and existing elevators, respectively. The fire fighters’ emergency operations requirements establish elevator recall activated by smoke detection in each elevator lobby and in associated elevator machine rooms. A three-position, key-operated switch, normally located in the main lobby at the elevator, controls the recall function — see [Exhibit 9.6](#). The requirements mandate specific functions for the “RESET,” “OFF,” and “ON” positions of this switch. The requirements also provide for *emergency in-car operations*, or what is often referred to as *fire fighters’ service*. Fire fighters’ service requires a three-position, key-operated switch in each elevator car, as shown in [Exhibit 9.7](#). The functions of the “OFF,” “HOLD,” and “ON” positions are specified in the elevator code. For specific details, refer to ASME A17.1/CSA B44. Explanatory material on these rules can be found in the *Handbook on Safety Code for Elevators and Escalators* ASME A17.1/CSA B44.<sup>15</sup>

**9.4.4 Number of Cars.** The number of elevator cars permitted in a hoistway shall be in accordance with [8.6.9.4](#).

**9.4.5\* Elevator Machine Rooms.** Elevator machine rooms that contain solid-state equipment for elevators, other than existing elevators, having a travel distance exceeding 50 ft (15 m) above the level of exit discharge, or exceeding 30 ft (9.1 m) below the level of exit discharge, shall be provided with independent ventilation or air-conditioning systems to maintain temperature during fire fighters’ emergency operations for elevator operation (*see*

**Exhibit 9.6**

Elevator lobby emergency operations key switch.

**Exhibit 9.7**

Elevator car emergency operations key switch.

9.4.3). The operating temperature shall be established by the elevator equipment manufacturer's specifications. When standby power is connected to the elevator, the machine room ventilation or air-conditioning shall be connected to standby power.

**A.9.4.5** Continued operation of solid-state elevator equipment is contingent on maintaining the ambient temperature in the range specified by the elevator manufacturer. If the machine room ventilation/air-conditioning is connected to the general building system, and that system is shut down during a fire, the fire department might lose the use of elevators due to excessive heat in the elevator machine room.

The intent of the requirement for a ventilation or an air-conditioning system to help keep the elevator controls operable is explained in 9.4.5 and A.9.4.5. For many typical installations, this requirement can be met by installing an independent, through-the-wall air-conditioning unit. Regardless of shutdown of the building's HVAC system, the independent unit will continue to run, provided that its power supply is not interrupted.

#### 9.4.6 Elevator Testing.

Because emergency responders might use elevators to move personnel and equipment, and potentially to assist in the evacuation of mobility-impaired occupants, it is important to routinely test elevators to help ensure they can be used when needed under fire and other emergency conditions.

**9.4.6.1** Elevators shall be subject to periodic inspections and tests as specified in ASME A17.1/CSA B44, *Safety Code for Elevators and Escalators*.

**9.4.6.2** All elevators equipped with fire fighters' emergency operations in accordance with 9.4.3 shall be subject to a monthly operation with a written record of the findings made and kept on the premises as required by ASME A17.1/CSA B44, *Safety Code for Elevators and Escalators*.

**9.4.6.3** The elevator inspections and tests required by 9.4.6.1 shall be performed at frequencies complying with one of the following:

- (1) Inspection and test frequencies specified in Appendix N of ASME A17.1/CSA B44, *Safety Code for Elevators and Escalators*
- (2) Inspection and test frequencies specified by the authority having jurisdiction

**9.4.7 Openings to Exit Enclosures.** Conveyors, elevators, dumbwaiters, and pneumatic conveyors serving various stories of a building shall not open to an exit enclosure.

Openings in exit enclosures are strictly limited by the provisions of 7.1.3.2.1(9) to doors that provide access to the exit from normally occupied spaces or corridors and means to leave the exit enclosure. Elevators and other conveyors are not considered

normally occupied areas. Additionally, an elevator, with its associated cables, controls, and mechanical equipment, would introduce combustibles into an exit enclosure, which conflicts with the objective of making the exit enclosure a safe place free of combustibles.

## 9.5 Waste Chutes, Incinerators, and Laundry Chutes

### 9.5.1 Enclosure.

**9.5.1.1** Waste chutes and laundry chutes shall be separately enclosed by walls or partitions in accordance with the provisions of Section 8.3.

**9.5.1.2** Chute intake openings shall be protected in accordance with Section 8.3.

**9.5.1.3** The doors of chutes specified in 9.5.1.2 shall open only to a room that is designed and used exclusively for accessing the chute opening.

**9.5.1.4** Chute service opening rooms shall be separated from other spaces in accordance with Section 8.7.

**9.5.1.5** The requirements of 9.5.1.1 through 9.5.1.4 shall not apply where otherwise permitted by the following:

- (1) Existing installations having properly enclosed service chutes and properly installed and maintained chute intake doors shall be permitted to have chute intake doors open to a corridor or normally occupied space.
- (2) Waste chutes and laundry chutes shall be permitted to open into rooms not exceeding 400 ft<sup>2</sup> (37 m<sup>2</sup>) that are used for storage, provided that the room is protected by automatic sprinklers.

Waste chutes are often associated with a trash collection room, and laundry chutes are often associated with a laundry/storage room. The provision of 9.5.1.5(2) permits chutes to open into such rooms, provided that the area of the room does not exceed 400 ft<sup>2</sup> (37 m<sup>2</sup>). Without this provision, the user might interpret the words "used exclusively" in 9.5.1.3 as limiting the use of that room to serving the chute only.

**9.5.2 Installation and Maintenance.** Waste chutes, laundry chutes, and incinerators shall be installed and maintained in accordance with NFPA 82, *Standard on Incinerators and Waste and Linen Handling Systems and Equipment*, unless such installations are approved existing installations, which shall be permitted to be continued in service.

Shafts containing waste and linen chutes, as shown in Exhibit 9.8, must be enclosed according to the requirements

Exhibit 9.8

Linen chute opening.

for the protection of vertical openings found in Section 8.6. The installation of the chute itself must meet the requirements of NFPA 82, *Standard on Incinerators and Waste and Linen Handling Systems and Equipment*.<sup>16</sup>

Additional concerns regarding chutes opening to other parts of the building need to be addressed. For convenience, service openings for loading are usually located to be accessible from corridors on the upper floors of the building. However, these corridors also serve as exit access, and a fire in the chute with an open loading door could result in the obstruction of the corridor by smoke and other products of combustion. To address this hazard, the Code and NFPA 82 require the construction of service opening rooms to form a buffer between the chute and the building space. The special hazard protection provisions in Section 8.7 for the separation of the service opening are referenced in 9.5.1.4. The result is a room that is separated from the rest of the building by construction with a 1-hour fire resistance rating or protected with an automatic extinguishing system. The door to this room is required to have a ¾-hour fire protection rating. Exhibit 9.9 illustrates the protection arrangement required for waste and linen chutes by NFPA 82.

Additionally, NFPA 82 requires the service opening room to be sized to maintain a minimum 6 in. (150 mm) clearance between the closed chute loading door and the closed room door. Exhibit 9.10 illustrates the measurement of this clearance.

## 9.6 Fire Detection, Alarm, and Communications Systems

### 9.6.1\* General.

Exhibit 9.9

Protection of waste and linen chutes.

Exhibit 9.10

Clearance in service opening room.

**A.9.6.1** The provisions of Section 9.6 cover the basic functions of a complete fire alarm system, including fire detection, alarm, and communications. These systems are primarily intended to provide the indication and warning of abnormal conditions, the

summoning of appropriate aid, and the control of occupancy facilities to enhance protection of life.

Some of the provisions of [Section 9.6](#) originated with *NFPA 72, National Fire Alarm and Signaling Code*. For purposes of this *Code*, some provisions of [Section 9.6](#) are more stringent than those of *NFPA 72*, which should be consulted for additional details.

The provision for early warning of fire accompanied by notification of emergency responders is a key element of a fire protection program. Where people are involved, protective signaling carries even greater importance. The intent of [A.9.6.1](#) is to provide guidance on establishing objectives for the performance of the fire alarm system and to allow individual system designs to address occupancy-specific variables.

Certain occupancies might not be required to have a fire alarm system at all. In industrial and storage occupancies, for example, the number of occupants in the facility or the hazard classification of the building's contents determines whether an alarm system is required. In small mercantile and business occupancies, there are usually enough people present (at least during a part of the day) to discover an incipient fire. For these occupancies, the *Code* imposes less rigid requirements for fire alarm systems than it does for certain other occupancies. Conversely, for health care occupancies, the provisions for fire alarm systems are quite detailed with respect to notification and emergency functions, such as the automatic closure of smoke barrier doors.

**9.6.1.1** The provisions of [Section 9.6](#) shall apply only where specifically required by another section of this *Code*.

[Section 9.6](#) applies only where specifically referenced by another section of the *Code*. Primarily, such references appear in the occupancy chapters. Careful attention to the provisions in the occupancy chapters is necessary, as they might contain references to specific paragraphs in [Section 9.6](#). For example, [12.3.4.1.1](#) for new assembly occupancies contains a general reference to all the requirements of [9.6.1](#); however, [12.3.4.3.5](#) contains a provision that permits the omission of visible signals in assembly seating areas where the occupant load exceeds 1000 and an alternative visible means of occupant notification acceptable to the AHJ, such as an electronic message board, is provided as indicated in [9.6.3.5.7](#).

**9.6.1.2** Fire detection, alarm, and communications systems installed to make use of an alternative permitted by this *Code* shall be considered required systems and shall meet the provisions of this *Code* applicable to required systems.

The provisions of [9.6.1.2](#) remind the user that a fire detection, an alarm, or an associated communications system that is installed to take advantage of a *Code* alternative becomes a required system and is subject to the same requirements as any other required system, including maintenance. An example of this provision is a new business occupancy that is not required to have a

fire alarm system on the basis of the thresholds established in [38.3.4.1](#). If, for security reasons, delayed-egress locks were to be installed, they would have to meet the provisions of [7.2.1.6.1. Paragraph 7.2.1.6.1.1\(1\)](#) requires that the locks automatically release upon the activation of an approved, supervised automatic sprinkler system in accordance with [Section 9.7](#); activation of any heat detector; or activation of not more than two smoke detectors of an approved, supervised automatic fire detection system installed in accordance with [Section 9.6](#). If a fire alarm system is utilized to automatically release a delayed-egress lock, it becomes a required system and must be installed and maintained in accordance with [Section 9.6](#).

**9.6.1.3** Fire alarm systems required by this *Code* shall be installed, tested, and maintained in accordance with the applicable requirements of *NFPA 70, National Electrical Code*, and *NFPA 72, National Fire Alarm and Signaling Code*, unless it is an approved existing installation, which shall be permitted to be continued in use.

**9.6.1.4\*** To ensure operational integrity, the fire alarm system shall have an approved maintenance and testing program complying with the applicable requirements of *NFPA 70, National Electrical Code*, and *NFPA 72, National Fire Alarm and Signaling Code*.

**A.9.6.1.4** Records of conducted maintenance and testing and a copy of the certificate of compliance should be maintained.

The operational integrity of a fire alarm system cannot be ensured without proper maintenance and testing. Thus, the *Code* requires that an approved — that is, acceptable to the authority having jurisdiction — maintenance and testing program be operational on an ongoing basis. An important part of the program is retention of system acceptance records and subsequent operational test records, so that comparisons can be made to initial system specifications.

**9.6.1.5\*** Fire alarm system impairment procedures shall comply with *NFPA 72, National Fire Alarm and Signaling Code*.

**A.9.6.1.5** A fire watch should at least involve some special action beyond normal staffing, such as assigning an additional security guard(s) to walk the areas affected. Such individuals should be specially trained in fire prevention and in occupant and fire department notification techniques, and they should understand the particular fire safety situation for public education purposes. (Also see *NFPA 601, Standard for Security Services in Fire Loss Prevention*.)

The term *out of service* in [9.6.1.5](#) is intended to imply that a significant portion of the fire alarm system is not in operation, such as an entire initiating device, signaling line, or notification appliance circuit. It is not the intent of the *Code* to require notification of the authority having jurisdiction, or evacuation of the portion of the building affected, for a single nonoperating device or appliance.

A fire alarm system might be shut down, or otherwise impaired, for any number of reasons during the life of a building. Some impairments are preplanned, controlled, and of short duration, such as during periodic testing and maintenance. Others might be preplanned and of longer duration, such as during times of building or system rehabilitation. Emergency shutdown of the system can be the result of power failure, fire, or other physical damage and might result in a short or lengthy shutdown to repair the system. Advance planning should help ensure that the system, or most of the system, can be restored to service despite the scope of the renovation or the extent of an unexpected impairment. If the alarm system is required by the *Code*, or if it was installed to make use of one of the alternatives offered by the *Code*, it must be in operable condition for the building to be considered *Code* compliant.

Instead of designating a building with an inoperative alarm system as noncompliant and prohibiting occupancy under all conditions in accordance with the provisions of 4.6.10.1, 9.6.1.5 mandates compliance with the fire alarm system impairment procedures specified by *NFPA 72*<sup>®</sup>, *National Fire Alarm and Signaling Code*<sup>17</sup>. In addition to notifying the building owner any time an alarm system or portion thereof is impaired, the service provider is required to notify the authority having jurisdiction when an alarm system is out of service for more than 8 hours. The 8-hour criterion specified by *NFPA 72* is intended to correspond with a typical work shift, such that if the alarm system remains impaired at the end of the work day, the authority having jurisdiction will be notified. If the AHJ determines the alarm system will be impaired for an extended period of time, means to mitigate the associated life safety risk can be implemented. Such means might include the establishment of a fire watch.

It is the intent of the *Code* that a fire watch result in a heightened awareness of the building's operations and environment. Individuals assigned to the fire watch should be able to recognize fire hazards and understand the procedures for occupant and fire department notification and occupant evacuation in an emergency.

When developing a plan to address system impairment, it is important to consider the nature of the impairment, the location, the increased hazards that are involved, and the actions necessary to mitigate the hazards. The authority having jurisdiction should be involved in the development of such a plan.

A parallel requirement in 9.11.2 addresses automatic sprinkler system impairments.

## 9.6.2 Signal Initiation.

**9.6.2.1** Where required by other sections of this *Code*, actuation of the fire alarm system shall occur by any or all of the following means of initiation but shall not be limited to such means:

- (1) Manual fire alarm initiation
- (2) Automatic detection
- (3) Extinguishing system operation

The capability for manual fire alarm initiation is a requirement common to all occupancies that require the installation of a fire alarm system. Initiation by automatic detection or extinguishing system operation is permitted to serve in lieu of manual initiation for some occupancies. In some cases, an occupancy chapter might require initiation by automatic detection or extinguishing system operation. For example, new educational occupancies are not generally required to have an automatic sprinkler system; however, if such a system is installed, 14.3.4.2.2 requires automatic alarm system initiation by operation of the sprinkler system in addition to the manual means. In new health care occupancies, automatic sprinklers are required, and 18.3.4.2.1 states that initiation of the alarm system is to be by manual means and by sprinkler system waterflow alarms. In new Class A mercantile occupancies, a fire alarm system and an automatic sprinkler system are required. However, 36.3.4.2(1) only requires alarm initiation by manual means. Alarm initiation by means of sprinkler system activation is permitted by 36.3.4.2(3) to serve in lieu of manual initiation, but it is not required.

Where both manual and automatic means for alarm system initiation are used, they should be complementary. If one system becomes inoperative — for example, failure of the manual initiation circuit — the second should continue to function properly and initiate the alarm upon automatic detection of fire or smoke.

**9.6.2.2** Manual fire alarm boxes shall be used only for fire-protective signaling purposes. Combination fire alarm and guard's tour stations shall be permitted.

**9.6.2.3** A manual fire alarm box shall be provided as follows, unless modified by another section of this *Code*:

- (1) For new alarm system installations, the manual fire alarm box shall be located within 60 in. (1525 mm) of exit doorways.
- (2) For existing alarm system installations, the manual fire alarm box either shall be provided in the natural exit access path near each required exit or within 60 in. (1525 mm) of exit doorways.

**9.6.2.4** Manual fire alarm boxes shall be mounted on both sides of grouped openings over 40 ft (12.2 m) in width, and within 60 in. (1525 mm) of each side of the opening.

The provisions of 9.6.2.3 and 9.6.2.4 are intended to correlate with the requirements of *NFPA 72*, *National Fire Alarm and Signaling Code*, for the placement of manual fire alarm boxes. Prior to the 2009 edition of the *Code*, manual fire alarm boxes were only required to be located near each required exit in the natural exit access path; such arrangement is still permitted by 9.6.2.3(2) for existing installations. For new installations, manual fire alarm boxes must be located within 60 in. (1525 mm) of exit doors, which include doors directly to the outside and doors to exit stair enclosures and exit passageways. See Exhibit 9.11 for an example of the application of 9.6.2.4 to manual fire alarm boxes at grouped openings.

Exhibit 9.11

Locations of manual fire alarm boxes at grouped openings.

**9.6.2.5\*** Additional manual fire alarm boxes shall be located so that, on any given floor in any part of the building, no horizontal distance on that floor exceeding 200 ft (61 m) shall need to be traversed to reach a manual fire alarm box.

**A.9.6.2.5** It is not the intent of 9.6.2.5 to require manual fire alarm boxes to be attached to movable partitions or to equipment, nor is it the intent to require the installation of permanent structures for mounting purposes only.

In a large open area, such as an exhibit hall, it would be impractical to require the installation of manual fire alarm boxes on mounting posts in the middle of the floor. However, it would be reasonable to apply the maximum spacing requirements to boxes located on the perimeter wall of the space.

**9.6.2.6\*** For fire alarm systems using automatic fire detection or waterflow detection devices to initiate the fire alarm system in accordance with Chapters 11 through 43, not less than one manual fire alarm box, located as required by the authority having jurisdiction, shall be provided to initiate a fire alarm signal.

**A.9.6.2.6** The manual fire alarm box required by 9.6.2.6 is intended to provide a means to manually activate the fire alarm system when the automatic fire detection system or waterflow devices are out of service due to maintenance or testing, or where human discovery of the fire precedes automatic sprinkler system or automatic detection system activation. Where the fire alarm system is connected to a monitoring facility, the manual fire alarm box required by 9.6.2.6 should be connected to a separate circuit that is not placed “on test” when the detection or sprinkler system is placed on test. The manual fire alarm box should be located in an area that is accessible to occupants of the building and should not be locked.

**9.6.2.7\*** Manual fire alarm boxes shall be accessible, unobstructed, and visible.

**A.9.6.2.7** Manual fire alarm boxes can include those with key-operated locks for detention areas or psychiatric hospitals,

manual fire alarm boxes in areas where explosive vapors or dusts might be a hazard, or manual fire alarm boxes in areas with corrosive atmospheres. The appearance of manual fire alarm boxes for special uses often differs from those used in areas of normal occupancy. Manual fire alarm boxes, such as those with locks, that are located in areas where the general public has limited access might need to have signage advising persons to seek assistance from staff in the event a fire is noted.

Paragraphs 9.6.2.3 through 9.6.2.7 establish the criteria for the placement of manual fire alarm boxes. The intent is to provide maximum visibility and easy access to increase the probability that building occupants will initiate an alarm as they exit the building. If alarm boxes are not located conveniently or are obstructed from view, it is unlikely that an occupant will look for one. A typical manual fire alarm box is shown in Exhibit 9.12.

The requirement of 9.6.2.6 is also found in *NFPA 72, National Fire Alarm and Signaling Code*, and is restated in the *Life Safety Code* for additional emphasis. This requirement affects initiation arrangement for occupancies that permit alarm initiation by automatic detection or extinguishing system operation in lieu of manual initiation. For example, a business occupancy using either 38.3.4.2(2) or (3) for alarm initiation would still be required to have one manual fire alarm box in the building at a location approved by the authority having jurisdiction. The single required fire alarm box is intended to be utilized to initiate the required fire alarm to provide occupant notification in the event the automatic initiation circuit is out of service for testing, maintenance, or repair. It is not necessarily intended to be accessible to the general public, although it might be if so required by the authority having jurisdiction.

**9.6.2.8** Where a sprinkler system provides automatic detection and alarm system initiation, it shall be provided with an approved alarm initiation device that operates when the flow of water is equal to or greater than that from a single automatic sprinkler.

Exhibit 9.12

Typical manual fire alarm box.

**9.6.2.9** Where a total (complete) coverage smoke detection system is required by another section of this *Code*, automatic detection of smoke in accordance with *NFPA 72, National Fire Alarm and Signaling Code*, shall be provided in all occupiable areas in environments that are suitable for proper smoke detector operation.

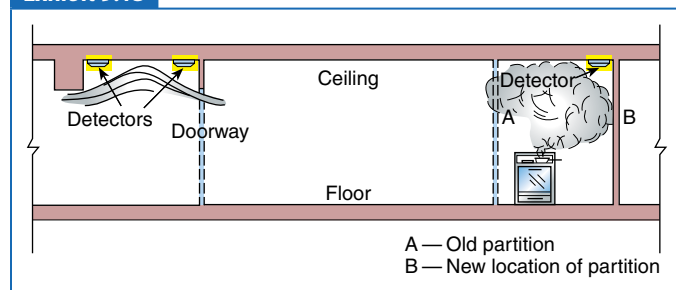

**Paragraph 9.6.2.9** specifies the locations for smoke detectors where a total (complete) coverage smoke detection system is required to be installed throughout an occupancy by another section of the *Code*. Smoke detection systems are not required by the *Code* in every occupancy where a fire alarm system is required. Many occupancies require neither a smoke detection system nor smoke alarms. For example, in business occupancies that are large enough to mandate the fire alarm requirement, the occupants are assumed to be awake and alert when the building is occupied, so the *Code* relies on the occupants to initiate the alarm via manual fire alarm boxes (see 38.3.4.2 and 39.3.4.2).

Other occupancies require smoke detection systems to be installed in selected areas. For example, in new nursing homes, smoke detection systems are generally required in the corridors (see 18.3.4.5.3). Where such limited coverage systems are required by the occupancy chapters, it is not necessary to meet the complete (total) coverage requirements of 9.6.2.9.

### 9.6.2.10 Smoke Alarms.

Smoke alarms need to be positioned correctly. If they are too close to a wall/ceiling intersection, particularly over a door, air currents might cause heat and smoke to bypass the unit completely. Likewise, their location with respect to a dropped beam or other construction can have a similar nullifying effect. Problems can arise where partitions are moved without regard to the location of existing detectors. These problems are illustrated in Exhibit 9.13. *NFPA 72, National Fire Alarm and Signaling Code*, provides extensive guidance in this area.

Exhibit 9.13

Detector location problems to be avoided.

The terms *smoke alarm* and *smoke detector* are frequently, and incorrectly, used interchangeably. A smoke alarm is a device that, upon the presence of smoke, sounds an integral alarm. Smoke alarms are typically powered by the building electrical system and might be provided with battery backup; in some cases, such as in existing one- and two-family dwellings, they are permitted to be powered solely by batteries. Smoke alarms are typically found within dwelling units and within sleeping rooms of lodging or rooming houses and hotels and dormitories, among others.

Smoke alarms can be either the single-station type or the multiple-station type. The term *single station* means that, when a smoke alarm senses smoke, only that device sounds its integral sounding alarm. The term *multiple-station* refers to smoke alarms that are interconnected such that, when one alarm senses smoke, all the interconnected devices sound their integral alarms. Multiple-station smoke alarms are typically interconnected within individual dwelling units to alert sleeping occupants located in different rooms to a fire in the dwelling.

A smoke detector is a component of a fire alarm system. In the presence of smoke, a smoke detector sends an electronic signal to the fire alarm control unit, which, in turn, initiates a predetermined action (such as activating the building evacuation alarm). Smoke detectors usually receive their power from the fire alarm system and contain no integral sounding devices.

In an occupancy such as a hotel, it might be desirable to protect the guest rooms with system smoke detectors rather than single-station smoke alarms. The *Code*, however, prohibits the guest room smoke detectors from sounding the general

building evacuation alarm (see 9.6.2.10.9). Provided that the system smoke detectors are arranged to function like single- or multiple-station smoke alarms by sounding an alarm only within the protected guest room or suite, and perhaps annunciate a supervisory signal at the front desk, 9.6.2.10.6 permits system smoke detectors to be used in the guest rooms in lieu of single- or multiple-station smoke alarms. The use of such system smoke detectors might provide an enhanced level of reliability, since the wiring connecting the detectors to the fire alarm control unit will be supervised for integrity in accordance with *NFPA 72, National Fire Alarm and Signaling Code*.

**9.6.2.10.1** Where required by another section of this *Code*, single-station and multiple-station smoke alarms shall be in accordance with *NFPA 72, National Fire Alarm and Signaling Code*, unless otherwise provided in 9.6.2.10.3, 9.6.2.10.4, 9.6.2.10.5, or 9.6.2.10.6.

**9.6.2.10.2** Where automatic smoke detection is required by Chapters 11 through 43, smoke alarms shall not be used as a substitute.

**9.6.2.10.3\*** The interconnection of smoke alarms shall apply only to new construction as provided in 9.6.2.10.8.

**A.9.6.2.10.3** *NFPA 72, National Fire Alarm and Signaling Code*, mandates smoke alarms in all sleeping rooms, and interconnection of smoke alarms is required for both new and existing installations. Per, 9.6.2.10.1, the residential occupancy chapters determine whether smoke alarms are needed within sleeping rooms. Paragraph 9.6.2.10.3 limits the requirement for interconnection of smoke alarms to those in new construction. This *Code* does not intend to require compliant, existing smoke alarm installations to be interconnected. This *Code* is periodically revised to add retrospective requirements only where the need is clearly substantiated.

**9.6.2.10.4\*** Smoke alarms and smoke detectors shall not be installed within an area of exclusion determined by a 10 ft (3.0 m) radial distance along a horizontal flow path from a stationary or fixed cooking appliance, unless listed for installation in close proximity to cooking appliances. Smoke alarms and smoke detectors installed between 10 ft (3.0 m) and 20 ft (6.1 m) along a horizontal flow path from a stationary or fixed cooking appliance shall be equipped with an alarm-silencing means or use photoelectric detection.

*Exception: Smoke alarms or smoke detectors that use photoelectric detection shall be permitted for installation at a radial distance greater than 6 ft (1.8 m) from any stationary or fixed cooking appliance when the following conditions are met:*

- (1) The kitchen or cooking area and adjacent spaces have no clear interior partitions or headers
- (2) The 10 ft (3.0 m) area of exclusion would prohibit the placement of a smoke alarm or smoke detector required by other sections of this *NFPA 72*. [72:29.8.3.4(4)]

**A.9.6.2.10.4** As per annex material located in A.29.5.1 of *NFPA 72*, it is not normally recommended that smoke alarms or smoke detectors be placed in kitchen spaces. This section of the code provides guidelines for safe installation if a need exists to install a smoke alarm or smoke detector in a residential kitchen space or cooking area.

Within this *Code* section, a fixed cooking appliance is any appliance that is intended to be permanently connected electrically to the wiring system or the fuel source. A stationary cooking appliance is any appliance that is intended to be fastened in place or located in a dedicated space and is connected to the supply circuit or fuel source.

Smoke alarms and smoke detectors that are currently available to consumers are susceptible to particles released into the air during normal cooking procedures. If smoke alarms and smoke detectors are placed too close to the area where the cooking source originates, a high level of nuisance alarms can occur. Frequent nuisance alarms can result in an occupant disabling the smoke alarm or smoke detector.

Nuisance alarm studies show that commercially available residential smoke alarms and smoke detectors are susceptible to nuisance alarms when installed too close to cooking appliances. As the horizontal distance between the smoke alarm or smoke detectors and the cooking appliance increases, the frequency of nuisance alarms decreases. Smoke alarms or smoke detectors that use ionization smoke detection have been shown to be more susceptible to cooking nuisance alarms than those that use photoelectric smoke detection when the alarms or detectors are installed within 10 ft (3.0 m) along a horizontal smoke travel path from a cooking appliance. Smoke alarms or smoke detectors that use photoelectric smoke detection produce nuisance alarms when installed less than 10 ft (3.0 m) from a cooking appliance, though to a lesser degree.

The occurrence of the higher frequency of nuisance alarms observed in smoke alarms or smoke detectors that use ionization detection have been documented in the fire research data. Due to the differences in technology between ionization detection and photoelectric detection, the sensitivity typically used for ionization detection is much higher than that used for photoelectric detection. This sensitivity difference is a result of each type of the detection being required to satisfy UL 217, *Single and Multiple Station Smoke Alarms*, performance tests. Removing detection technology from consideration, the frequency of nuisance alarms is solely due to the sensitivity of the detection method used. Thus, both ionization and photoelectric detector technologies will produce nuisance alarms due to cooking, but currently available smoke alarms and smoke detectors that use ionization detection typically produce more cooking related nuisance alarms.

The higher sensitivities of currently available smoke alarms and smoke detectors that use ionization detection do provide a benefit at the expense of a potentially higher rate of cooking-related nuisance alarms. Research has demonstrated that ionization detection will typically respond faster than photoelectric

detection to flaming fires, providing earlier warning to occupants that might allow for quicker intervention or faster egress. In general, the installation of smoke alarms or smoke detectors that use ionization detection will result in increased fire safety at the risk of a higher frequency of nuisance alarms. The installation of smoke alarms or smoke detectors that use photoelectric detection will result in reduced fire safety for flaming fires and a reduced risk of nuisance alarms. Based on the trade-off between faster response to fires and the frequency of nuisance alarms, detectors that utilize both technologies (i.e., ionization, photoelectric, and a combination) are allowed to be installed between 10 ft (3.0 m) and 20 ft (6.1 m) along a horizontal flow path from a standard or fixed cooking appliance if the specific detector is equipped with an alarm silencing means or is of the photoelectric type. Nuisance alarm studies provide data on cooking nuisances

that emanate from both fixed cooking appliances and stationary cooking appliances (e.g., stove, oven) as well as portable cooking appliances (e.g., toaster). Based on these studies, which demonstrate the potential of all cooking appliances to generate nuisance sources, a zone of exclusion has been specified surrounding each stationary or fixed cooking appliance. The purpose of this zone is to limit the installation of smoke alarms and detectors in areas where stationary, fixed, or portable cooking appliances will be located within the residential kitchen space such that potential nuisance alarms are minimized. The size of the zone of exclusion is specified to attempt to take into account the unknown and transitory locations of portable cooking appliances. This zone of exclusion is determined by measuring a 10 ft (3.0 m) radial distance from the closest edge of a stationary or fixed cooking appliance. The zone of exclusion is not intended to pass through walls or doorways. **Figure A.9.6.2.10.4(a)** provides an example of the zone of exclusion in a generalized residential kitchen. If other areas of this *Code* require that a smoke alarm or smoke detector be placed within a horizontal flow path distance between 10 ft (3.0 m) and 20 ft (6.1 m) from a stationary or fixed cooking appliance, the following method should be used to determine the distance, and only photoelectric detection or smoke alarms/detectors with alarm silencing means can be installed in this area.

To install a smoke alarm or detector between 10 ft (3.0 m) and 20 ft (6.1 m) from the cooking appliance, an installer must first determine the 10 ft (3.0 m) area of exclusion. Once the area of exclusion is determined, an installer must then determine the horizontal flow distance. This is the horizontal distance along the ceiling from the closest edge of the cooking appliance to the smoke alarm or detector. The horizontal distance can consist of line segments due to impediments, such as interior partitions. Once an impediment is met, the measurement of the distance will then continue along the new horizontal path segment until the distance requirement is met or another impediment is encountered. **Figure A.9.6.2.10.4(b)** provides an example for placement

**Figure A.9.6.2.10.4(a)** Example of Zone of Exclusion (gray area) Within Typical Residential Kitchen. [72: Figure A.29.8.3.4(4)(a)]

**Figure A.9.6.2.10.4(b)** Example of Smoke Alarm or Smoke Detector Placement Between 10 ft (3.0 m) and 20 ft (6.1 m) Away in Hallway from Center of Stationary or Fixed Cooking Appliance. [72: Figure A.29.8.3.4(4)(b)]

**Figure A.9.6.2.10.4(c)** Example of Smoke Alarm or Smoke Detector Placement Between 10 ft (3.0 m) and 20 ft (6.1 m) Away in Hallway from Center of Stationary or Fixed Cooking Appliance. [72: Figure A.29.8.3.4(4)(c)]

**Figure A.9.6.2.10.4(d)** Example of Exception Placement of Photoelectric Smoke Alarm or Smoke Detector at 72 in. (1.83 m) from Stationary or Fixed Cooking Appliance. [72: Figure A.29.8.3.4(4)(d)]

outside a kitchen in a nearby hallway. **Figure A.9.6.2.10.4(c)** provides another example of appropriate placement outside of a kitchen in an adjacent room. At a horizontal flow path distance of greater than 20 ft (6.1 m), any type of smoke alarm or smoke detector can be installed. In rare cases, a residential dwelling can be of such size and configuration that an area of exclusion of 10 ft (3.0 m) from a stationary or fixed cooking appliance excludes the placement of a smoke alarm or smoke detector required by other areas of this *Code*. In these cases, a smoke alarm or smoke detector using photoelectric detection can be installed at least 72 in. (1.83 m) from the fixed or stationary cooking appliance. **Figure A.9.6.2.10.4(d)** provides an example

of this situation in practice where a smoke alarm or smoke detector is required outside of the sleeping area but the space is in close proximity to the kitchen space. [72: A.29.8.3.4(4)]

**9.6.2.10.5\*** Smoke alarms and smoke detectors shall not be installed within a 36 in. (910 mm) horizontal path from a door to a bathroom containing a shower or tub unless listed for installation in close proximity to such locations. [72:29.8.3.4 (6)]

**A.9.6.2.10.5** Studies indicate that smoke alarms and smoke detectors that use ionization detection, photoelectric detection, or a combination of ionization and photoelectric detection are susceptible to nuisance alarms caused by steam. Little research

has been done on the comparative response of these types of detection to steam. Steam particles, in general, are visible, reflect light easily, and are typically produced in a size range that would be more likely to activate a photoelectric sensor. Thus, it is required that smoke alarms and smoke detectors be installed greater than 36 in. (910 mm) from the bathroom door where possible. Increasing the distance between the smoke alarm or smoke detector and the bathroom door can reduce the frequency of nuisance alarms from bathroom steam. Frequent nuisance alarms can result in the occupant disabling the smoke alarm. Each incremental increase in separation, up to 10 ft (3.0 m), between the bathroom door and the smoke alarm or smoke detector is expected to reduce the frequency of nuisance alarms. [72: A.29.8.3.4(5)]

The requirements of 9.6.2.10.4 and 9.6.2.10.5 are extracted from *NFPA 72, National Fire Alarm and Signaling Code*, and are new to the 2015 edition of the *Code*. The minimization of nuisance alarms is essential to help reduce the number of disabled smoke alarms. The technical committee responsible for smoke alarm requirements in *NFPA 72* reviewed the available information on the occurrence of nuisance alarms and concluded that the primary source of nuisance alarms was cooking activities. Steam from bathroom activities was also a source but to a much more limited extent. Nuisance alarms caused by cooking activities occur far more frequently with ionization smoke alarms than with photoelectric smoke alarms. However, nuisance alarms from either type of smoke alarm are likely if the smoke alarm is placed too close to a cooking appliance. For that reason, 9.6.2.10.4 excludes the installation of any smoke alarm within 10 ft (3.0 m) of a stationary or fixed cooking appliance. The exclusion area can be reduced to 6 ft (1.8 m) under the circumstance specified in the exception. A further exclusion area between 10 ft (3.0 m) and 20 ft (6.1 m) is specified similar to that in previous editions of *NFPA 72*. No exclusion is specified beyond 20 ft (6.1 m). Exhibit 9.14 shows an example of a photoelectric smoke

Exhibit 9.14

Photoelectric smoke detector located between 10 ft (3.0 m) and 20 ft (6.1 m) from cooking appliance. (Source: R. P. Schiffliti Associates, Inc., Reading, MA)

detector located between 10 ft (3.0 m) and 20 ft (6.1 m) from a cooking appliance.

Nuisance alarms caused by steam from bathroom activities occurred in both types of smoke alarms. Refer to A.9.6.2.10.5 for additional guidance on the location of smoke alarms near bathrooms.

**9.6.2.10.6** System smoke detectors in accordance with *NFPA 72, National Fire Alarm and Signaling Code*, and arranged to function in the same manner as single-station or multiple-station smoke alarms shall be permitted in lieu of smoke alarms.

**9.6.2.10.7** Smoke alarms, other than battery-operated smoke alarms as permitted by other sections of this *Code*, shall be powered in accordance with the requirements of *NFPA 72, National Fire Alarm and Signaling Code*.

Single-station and multiple-station smoke alarms, unless exempted by 9.6.2.10.7, must be powered as required by *NFPA 72, National Fire Alarm and Signaling Code*. In general, they must be powered by the building electrical system; they must not rely solely on battery power. This provision is based on the experience that battery-operated smoke alarms do not provide the reliability with respect to uninterrupted power supply that building electrical system power provides. Batteries are often removed to avoid nuisance alarms caused by cooking or steam from showers, or for use in other devices, such as radios and electronic toys; dead batteries are often not replaced. However, 9.6.2.10.7 allows the occupancy chapters to permit battery-operated, single-station smoke alarms. The use of battery-operated smoke alarms is permitted in existing one- and two-family dwellings; in existing lodging or rooming houses; and, under certain conditions, in existing residential board and care facilities.

It is not the intent of 9.6.2.10.7 to prohibit low-power wireless technology, in which a battery-operated alarm reports by radio transmission to a fire alarm control unit, if such a device complies with *NFPA 72*. In turn, *NFPA 72* requires such systems to indicate a missing battery or low battery power condition at the remotely located alarm system panel. Compliance with the provisions of *NFPA 72* applicable to low-power wireless systems increases the power source reliability to a level comparable to that provided by connection to the building electrical service.

**9.6.2.10.8\*** In new construction, where two or more smoke alarms are required within a dwelling unit, suite of rooms, or similar area, they shall be arranged so that operation of any smoke alarm shall cause the alarm in all smoke alarms within the dwelling unit, suite of rooms, or similar area to sound, unless otherwise permitted by one of the following:

- (1) The requirement of 9.6.2.10.8 shall not apply where permitted by another section of this *Code*.
- (2) The requirement of 9.6.2.10.8 shall not apply to configurations that provide equivalent distribution of the alarm signal.

**A.9.6.2.10.8** A dwelling unit is that structure, area, room, or combination of rooms, including hotel rooms/suites, in which a family or individual lives. A dwelling unit includes living areas only and not common usage areas in multifamily buildings, such as corridors, lobbies, and basements.

Audibility over background noises, such as running water, home appliances, and audio systems, with intervening doors closed between the occupants and the smoke alarm sounding device, is of key importance. In multistory or large-area living units, multiple smoke alarms should be interconnected, so that the sensing of smoke by one sounds the alarms of all devices within that living unit.

*NFPA 72, National Fire Alarm and Signaling Code*, specifies the audibility requirements for alarm signals in sleeping areas. Audible appliances must have a sound level that is at least 15 dB above the average ambient sound level, 5 dB above the maximum sound level having a duration of at least 60 seconds, or a sound level of at least 75 dBA, whichever is greater. The sound level is measured at the pillow level in the sleeping room, with any doors between the sleeping room and the audible appliance in the closed position.

**9.6.2.10.9** The alarms described in **9.6.2.10.8** shall sound only within an individual dwelling unit, suite of rooms, or similar area and shall not actuate the building fire alarm system, unless otherwise permitted by the authority having jurisdiction.

**9.6.2.10.10** Smoke alarms shall be permitted to be connected to the building fire alarm system for the purpose of annunciation in accordance with *NFPA 72*.

The intent behind requiring smoke alarms within individual living units without requiring connection to the building fire alarm system is to provide notification of a smoke condition within a guest room, guest suite, or dwelling unit to its occupants. Once the occupants escape from their unit to the building's common areas, they can use the manual fire alarm boxes to sound the building alarm to notify the remaining building occupants of the emergency.

Interconnection of dwelling unit smoke detectors to the building fire alarm system can result in numerous nuisance alarms due to the detection of cooking vapors or steam from showers. Nuisance alarms can lead to complacency, or worse, the deliberate disablement of the system and the resulting lack of early warning. Thus, where a complete fire detection (versus smoke detection) system is required, it usually includes system smoke detection within building common areas and system heat detection within individual dwelling units. Single- or multiple-station smoke alarms are then still necessary within each dwelling unit to afford the occupants of each unit early warning of smoke conditions within their unit.

### 9.6.3 Occupant Notification.

**9.6.3.1** Occupant notification shall be provided to alert occupants of a fire or other emergency where required by other sections of this *Code*.

**9.6.3.2** Occupant notification shall be in accordance with **9.6.3.3** through **9.6.3.10.2**, unless otherwise provided in **9.6.3.2.1** through **9.6.3.2.4**.

Note that **9.6.3.5** requires occupant notification to be provided by audible and visible signals. Thus, where an occupancy chapter requires an alarm system that provides occupant notification in accordance with **Section 9.6**, visible signals, as well as the traditional audible signals, must be provided. Several exemptions to the requirement for visible signals are provided in **9.6.3.5.1** through **9.6.3.5.8**. For example, existing alarm systems are exempt from the requirement for visible signals per **9.6.3.5.3**.

**9.6.3.2.1\*** Elevator lobby, hoistway, and associated machine room smoke detectors used solely for elevator recall, and heat detectors used solely for elevator power shutdown, shall not be required to activate the building evacuation alarm if the power supply and installation wiring to such detectors are monitored by the building fire alarm system, and if the activation of such detectors initiates a supervisory signal at a constantly attended location.

**A.9.6.3.2.1** Elevator lobbies have been considered areas subject to unwanted alarms due to factors such as low ceilings and smoking. In the past several years, new features have become available to reduce this problem. These features are, however, not necessarily included in any specific installation.

**9.6.3.2.2\*** Smoke detectors used solely for closing dampers or heating, ventilating, and air-conditioning system shutdown shall not be required to activate the building evacuation alarm, provided that the power supply and installation wiring to the detectors are monitored by the building fire alarm system, and the activation of the detectors initiates a supervisory signal at a constantly attended location.

**A.9.6.3.2.2** The concept addressed is that detectors used for releasing service, such as door or damper closing and fan shutdown, are not required to sound the building alarm.

**9.6.3.2.3\*** Smoke detectors located at doors for the exclusive operation of automatic door release shall not be required to activate the building evacuation alarm, provided that the power supply and installation wiring to the detectors are monitored by the building fire alarm system, and the activation of the detectors initiates a supervisory signal at a constantly attended location.

**A.9.6.3.2.3** The concept addressed is that detectors used for releasing service, such as door or damper closing and fan shutdown, are not required to sound the building alarm.

**9.6.3.2.4** Detectors in accordance with **22.3.4.3.1(2)** and **23.3.4.3.1(2)** shall not be required to activate the building evacuation alarm.

The provisions of **9.6.3.2.1** through **9.6.3.2.4** reaffirm that not all detectors are required to sound the building alarm simply because they are installed on the premises. Detectors used for

releasing service, such as for the release of an automatic door hold-open device that allows a door to be self-closing in the presence of smoke, need only perform their intended function as long as the detector wiring is monitored and a supervisory signal is annunciated at a constantly attended location when the detectors activate. In areas where smoke detection — complete with occupant notification via the building alarm system — is needed to provide the intended level of life safety, the *Code* specifically requires either a complete or partial smoke detection system. Interconnection with the building alarm should not be mandated in the hope of receiving additional detection coverage; such a detector might have been installed for another purpose, such as releasing service.

New health care occupancies, via 18.3.4.3.1, are prohibited from using 9.6.3.2.3. Thus, if a smoke detector is installed as part of an automatic door release system (see 7.2.1.8.2), the activation of the detector must result in occupant notification through the building fire alarm system.

**9.6.3.3** Where permitted by Chapters 11 through 43, a presignal system shall be permitted where the initial fire alarm signal is automatically transmitted without delay to a municipal fire department, to a fire brigade (if provided), and to an on-site staff person trained to respond to a fire emergency.

Instead of immediately and automatically sounding a general alarm throughout the building, a presignal system delays the general alarm by sounding an alarm only at an approved and constantly attended area. This area could be, for example, a fire brigade station, guard station, or similar location with staff trained to investigate the signal's origin and subsequently activate a general alarm if necessary.

A delay in sounding the general alarm is inherent in a presignal system, but the delay might do more harm than good in those occupancies with populations that are difficult to evacuate or protect. Therefore, the *Code* requires an occupancy chapter to specifically recognize a presignal system to permit its use. No new occupancy chapter permits presignal systems, but they are permitted in some existing occupancies. For example, 40.3.4.3.3 permits an existing presignal system in an industrial occupancy.

A presignal system used in accordance with the provisions of 9.6.3.3 is permitted to delay only the general occupant notification and must, at time of initiation, achieve immediate and automatic notification of emergency forces.

**9.6.3.4** Where permitted by Chapters 11 through 43, a positive alarm sequence shall be permitted, provided that it is in accordance with *NFPA 72, National Fire Alarm and Signaling Code*.

Given that smoke detector sensitivity should result in alarm system initiation sooner than that achieved by either heat detection or manual discovery and use of a pull station, 9.6.3.4 addresses positive alarm sequence, which has detailed requirements in *NFPA 72, National Fire Alarm and Signaling Code*. Positive alarm sequence offers relief from nuisance alarms in buildings

equipped with detection technology by permitting a delay in occupant notification. The detector senses smoke, automatically and without delay, sending an alarm signal to a constantly attended location, so that trained staff can investigate the origin of the signal. Positive alarm sequence includes all of the following features:

1. The signal received at the attended location must be acknowledged within 15 seconds, or immediate activation of notification signals in accordance with the building evacuation or relocation plan and remote signals must occur.
2. Trained personnel have up to 180 seconds during the alarm investigation phase to evaluate the fire condition and reset the system; if the system is not reset within 180 seconds, immediate activation of notification signals in accordance with the building evacuation or relocation plan and remote signals must occur.
3. If a second automatic fire detector is actuated during the investigation phase, immediate activation of notification signals in accordance with the building evacuation or relocation plan and remote signals must occur.
4. If any other initiating device, such as a manual fire alarm box, is actuated during the investigation phase, immediate activation of notification signals in accordance with the building evacuation or relocation plan and remote signals must occur.
5. The system must provide a means to bypass the positive alarm sequence.

Positive alarm sequence is permitted only if an occupancy chapter specifically allows it by direct reference to 9.6.3.4. The only occupancies that do not permit occupant notification by positive alarm sequence are new and existing residential board and care occupancies.

**9.6.3.5** Unless otherwise provided in 9.6.3.5.1 through 9.6.3.5.8, notification signals for occupants to evacuate shall be by audible and visible signals in accordance with *NFPA 72, National Fire Alarm and Signaling Code*, and *ICC/ANSI A117.1, American National Standard for Accessible and Usable Buildings and Facilities*, or other means of notification acceptable to the authority having jurisdiction.

**9.6.3.5.1** Areas not subject to occupancy by persons who are hearing impaired shall not be required to comply with the provisions for visible signals.

Visible alarm devices, in addition to audible alarms, are needed in buildings occupied by persons who are hearing impaired. The provision of 9.6.3.5.1 recognizes that not all buildings are subject to occupancy by those who are hearing impaired. For example, in a high hazard industrial occupancy where, due to employee safety concerns, an adequate hearing level has been judged to be a legitimate condition of employment, there should be no life safety need for visible signals in addition to the audible signals. As the provisions of the Americans with Disabilities Act and

Architectural Barriers Act Accessibility Guidelines for Buildings and Facilities,<sup>18</sup> discussed in the commentary associated with 7.2.12, receive wider implementation or are expanded in scope, few locations will exist where it is certain that persons with hearing impairments will not be present.

**9.6.3.5.2** Visible-only signals shall be provided where specifically permitted in health care occupancies in accordance with Chapters 18 and 19.

**9.6.3.5.3** Existing alarm systems shall not be required to comply with the provision for visible signals.

**9.6.3.5.4** Visible signals shall not be required in lodging or rooming houses in accordance with Chapter 26.

**9.6.3.5.5** Visible signals shall not be required in exit stair enclosures.

**9.6.3.5.6** Visible signals shall not be required in elevator cars.

Visible occupant notification appliances are not required to be installed in exit stairs or elevator cars as noted in 9.6.3.5.5 and 9.6.3.5.6, respectively. These provisions recognize that, upon entering an exit stair, occupants have reached a safe location and are in the process of egressing the building. Notification appliances in exit stair enclosures can create confusion and slow down the evacuation process. Likewise, if an occupant is in an elevator and the building alarm activates, occupants will become aware of the alarm condition when the doors open and proceed to egress the building. See also 9.6.3.6.4 and 9.6.3.6.5 for parallel provisions addressing audible notification appliances.

**9.6.3.5.7\*** Public mode visual notification appliances in accordance with *NFPA 72, National Fire Alarm and Signaling Code*, shall not be required in designated areas as permitted by Chapters 11 through 43, provided that they are replaced with approved alternative visible means.

**A.9.6.3.5.7** Visual notification appliances installed in large-volume spaces, such as arenas, stadiums, malls, and atriums, can be alternative devices that are not listed as visible notification appliances for fire alarm systems, provided that the notification objective of the visual signal is reasonably achieved. Examples of alternative devices include, but are not limited to, scoreboards, message boards, and other electronic devices that meet the performance objectives of visible fire alarm appliances in large-volume spaces.

It is the intent to permit the omission of visible notification appliances as identified in 9.6.3.5.7, provided that the adjacent areas that have not been specifically designated as exempt are provided with visible notification as required by 9.6.3.5.

**9.6.3.5.8\*** Where visible signals are not required, as permitted by 9.6.3.5.7, documentation of such omission shall be maintained in accordance with 9.13.3.

**A.9.6.3.5.8** Documentation should be maintained with the as-built drawings so that inspection and testing personnel understand

that the visible appliances have been exempted from certain areas and, therefore, can note the deviation on the acceptance test documentation and ongoing inspection reports. This will provide inspection and testing personnel with necessary details regarding the omission of visible notification appliances.

In large-volume spaces, such as stadiums, standard visual alarm notification appliances (strobes) might not prove to be effective for hearing-impaired occupants. The provisions of 9.6.3.5.7 and 9.6.3.5.8 permit alternative means of visual notification, provided that permission is granted by the applicable occupancy chapter (only new assembly occupancies with an occupant load of more than 1000 are currently permitted to utilize the provision of 9.6.3.5.7 via 12.3.4.3.5). Such alternative means of visual notification might be provided by electronic signage or video displays strategically located throughout the space or by the electronic scoreboards provided within a stadium or arena. It is anticipated that, in such occupancies, hearing-impaired occupants will not only see the messages, but they will also take cues from other occupants responding to the audible alarm notification.

**9.6.3.6** The general evacuation alarm signal shall operate in accordance with one of the methods prescribed by 9.6.3.6.1 through 9.6.3.6.3.

**9.6.3.6.1** The general evacuation alarm signal shall operate throughout the entire building other than the locations described in 9.6.3.6.4 and 9.6.3.6.5.

**9.6.3.6.2\*** Where total evacuation of occupants is impractical due to building configuration, only the occupants in the affected zones shall be initially notified, and provisions shall be made to selectively notify occupants in other zones to afford orderly evacuation of the entire building, provided that such arrangement is approved by the authority having jurisdiction.

**A.9.6.3.6.2** To approve an evacuation plan to selectively notify building occupants, the authority having jurisdiction should consider several building parameters, including building compartmentation, detection and suppression system zones, occupant loads, and the number and arrangement of the means of egress.

In high-rise buildings, it is typical to evacuate the fire floor, the floor(s) above, and the floor immediately below. Other areas are then evacuated as the fire develops.

The provision of 9.6.3.6.2 typically applies to high-rise buildings. It provides for zoned, staged evacuation. This provision anticipates that the portions of the building that do not receive the initial alarm are separated from the areas of immediate emergency by adequate fire resistance-rated construction, such as the 2-hour fire separation that is usually provided between floors of high-rise buildings.

The use of staged evacuation requires occupants to be regularly trained and to have a basic understanding of the building's life safety systems and features. After witnessing the collapse of the World Trade Center on September 11, 2001, many building

occupants might not be comfortable remaining in a high-rise building under any fire condition. By conducting routine training, their comfort level can be increased by raising their awareness of how buildings are designed to limit the spread of fire from the area of origin through compartmentation and the installation of automatic sprinkler systems. This training becomes very important, since the exit stairs in most existing high-rise buildings are not designed to accommodate the simultaneous evacuation of the entire building population. See 7.2.2.2.1.2 for increased stair width requirements where serving 2000 occupants or more that have been in the Code since the 2006 edition.

**9.6.3.6.3** Where occupants are incapable of evacuating themselves because of age, physical or mental disabilities, or physical restraint, all of the following shall apply:

- (1) The private operating mode, as described in *NFPA 72, National Fire Alarm and Signaling Code*, shall be permitted to be used.
- (2) Only the attendants and other personnel required to evacuate occupants from a zone, area, floor, or building shall be required to be notified.
- (3) Notification of personnel as specified in 9.6.3.6.3(2) shall include means to readily identify the zone, area, floor, or building in need of evacuation.

The provisions of 9.6.3.6.3, which address the private operating mode for occupant notification, frequently apply to health care occupancies and detention and correctional occupancies. It is common in these occupancies to use coded messages or a similar method to announce the occurrence and location of a fire emergency throughout the facility. This allows all members of the emergency response team, regardless of current location within a potentially sprawling facility, to respond to their assigned emergency duties. For example, despite the fact that the facility engineer might be in a building remote from that having the emergency when the coded alarm sounds throughout the facility, the engineer will receive the proper notification to carry out the previously assigned task of checking the fire pump to ensure that it is ready to operate, if needed.

*NFPA 72, National Fire Alarm and Signaling Code*, modifies the requirements for the placement of visible notification appliances where the private operating mode is utilized. For example, it might not be necessary to locate visible notification appliances in the patient rooms of a hospital or nursing home, since notification is intended to be provided via a coded message to staff, who will initiate the emergency plan. In such a case, visible signals might be limited to those areas subject to occupancy by the general public (such as lobbies, corridors, cafeterias, public restrooms, and other similar spaces). The authority having jurisdiction ultimately determines where visible notification appliances must be located.

**9.6.3.6.4** The general evacuation signal shall not be required in exit stair enclosures.

**9.6.3.6.5** The general evacuation signal shall not be required in elevator cars.

**9.6.3.7** Audible alarm notification appliances shall be of such character and so distributed as to be effectively heard above the average ambient sound level that exists under normal conditions of occupancy.

The authority having jurisdiction should review carefully the types and locations of fire alarm notification appliances. Given that audibility above ambient sound level is of primary importance and that each additional sounding device adds cost to a system, a balance should be maintained so that excessive costs are not incurred, while the installation of sufficient devices for adequate audibility is ensured. The provision of sufficient devices is extremely important in hotels and apartment buildings. Sounding devices located in corridors might not be audible within living units or guest rooms, especially in newer construction, due to the increased use of acoustical insulation for sound isolation.

In newer hotels, it has become common to install alarm notification appliances within each guest room to meet the audibility requirements of *NFPA 72, National Fire Alarm and Signaling Code*. With water running in the bathroom, the television operating on high volume, and the air-conditioning system in use, the horn or speaker within the room achieves the required occupant notification, whereas a similar device located in the corridor alone might not. Additionally, the alarm device often used is a speaker that can produce an alarm tone or deliver a specific voice message. A speaker device is particularly useful in a high-rise building; although it is important to get an initial message to all rooms, there may also be a need to send different messages to different parts of the building as part of a zoned or staged evacuation plan. See the commentary following A.9.6.3.6.2 for additional information on staged evacuation.

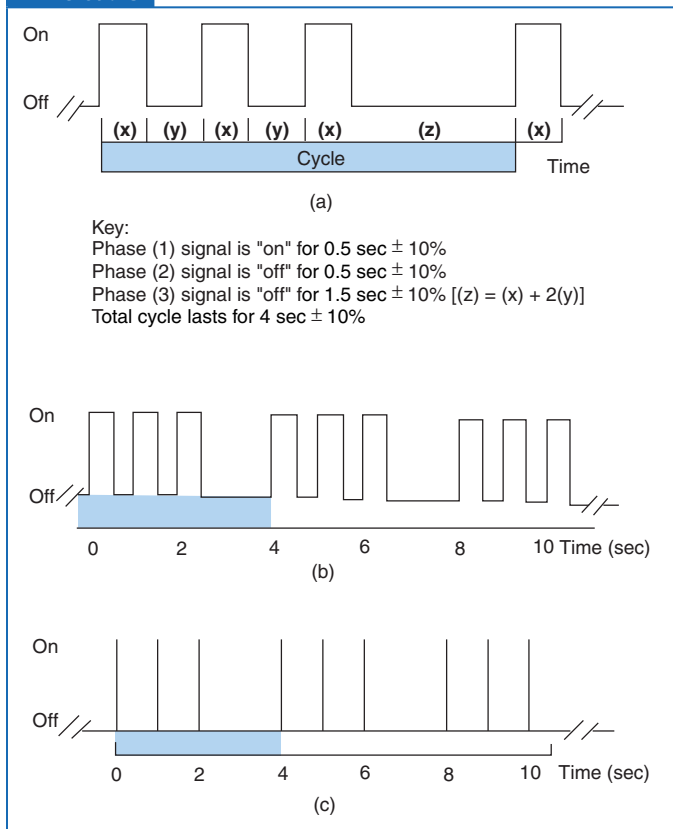

**9.6.3.8** Audible alarm notification appliances shall produce signals that are distinctive from audible signals used for other purposes in a given building.

Where the provisions of Chapters 11 through 43 require an evacuation alarm signal, the standard fire alarm evacuation signal described in *NFPA 72, National Fire Alarm and Signaling Code*, should be used. The standard fire alarm evacuation signal is a three-pulse temporal pattern using any appropriate sound. This signal is illustrated in Exhibit 9.15. The pattern consists of an "on" phase (1) lasting 0.5 second followed by an "off" phase (2) lasting 0.5 second, for three successive "on" periods; these are followed by an "off" phase (3) lasting 1.5 seconds. The signal should be repeated for a period appropriate for the purposes of evacuation of the building, but for not less than 180 seconds. A single-stroke bell or chime sounded at "on" intervals lasting 1 second, with a 2-second "off" interval after each third "on" stroke, is permitted.

The manner of sounding alarms should be standardized to obtain uniformity throughout as large a geographic area as practicable, so that people moving from one location to

Exhibit 9.15

Standard fire alarm evacuation signal.

another will not be misled or confused by differences in the manner of sounding alarms.

Two multiple-fatality fires in hotel occupancies that occurred in late 1978 and 1979 illustrate the need for standardized fire alarm signals with adequate audibility. In both incidents, which occurred in the middle of the night, many survivors reported not hearing any alarm device or mistaking the alarm for telephones or alarm clocks. An additional multiple-fatality fire in a hotel in 1978 illustrated the special problems with alarm notification where occupants are hearing impaired. In this fire, several elderly occupants removed hearing aids before going to bed, thus challenging the adequacy of the alarm's audibility.

**9.6.3.9** Automatically transmitted or live voice evacuation or relocation instructions shall be permitted to be used to notify occupants and shall comply with either 9.6.3.9.1 or 9.6.3.9.2.

Where occupant notification is provided by voice announcements, the notification means must comply with either: (1) *NFPA 72, National Fire Alarm and Signaling Code*, as referenced in 9.6.3.9.1; or (2) the alternative criteria specified in 9.6.3.9.2 where permitted by Chapters 11 through 43.

**9.6.3.9.1** Automatically transmitted or live voice evacuation or relocation instructions shall be in accordance with *NFPA 72, National Fire Alarm and Signaling Code*.

**9.6.3.9.2\*** Where permitted by Chapters 11 through 43, automatically transmitted or live voice announcements shall be permitted to be made via a voice communication or public address system that complies with all of the following:

- (1) Occupant notification, either live or recorded, shall be initiated at a constantly attended receiving station by personnel trained to respond to an emergency.
- (2) An approved secondary power supply shall be provided for other than existing, previously approved systems.
- (3) The system shall be audible above the expected ambient noise level.
- (4) Emergency announcements shall take precedence over any other use.

**A.9.6.3.9.2** The provisions of 9.6.3.9.2 offer an alternative to the emergency voice alarm and communications system provisions (live voice or recorded voice announcements) of *NFPA 72, National Fire Alarm and Signaling Code*. Occupancies such as large-venue assembly occupancies and mercantile mall buildings are occupancies in which the physical configuration (e.g., large-volume spaces), function, and human behavior (including elevated levels of occupant-generated noise) present challenges with respect to effective occupant notification by standard means in accordance with *NFPA 72*. Because the routine operation of these occupancies demands highly reliant, acoustically capable, and sufficiently audible public address systems, properly trained staff can be relied on to use these public address systems to effect occupant evacuation, relocation, or both.

As 9.6.3.9.2 specifically permits an alternative means of notification to that prescribed by *NFPA 72*, it does not mandate that the secondary power supply and the intelligibility and audibility facets of the public address system comply with *NFPA 72* or suggest that equivalency with the related provisions of *NFPA 72* is required. However, it is anticipated that, when approving the secondary power and audibility capabilities of public address systems, authorities having jurisdiction will ensure that these systems are conceptually comparable to the emergency voice alarm and communications system provisions of *NFPA 72*, such that a reliable and effective occupant notification system is provided.

The voice announcement occupant notification criteria in 9.6.3.9.2 provides an alternative arrangement to that specified by *NFPA 72, National Fire Alarm and Signaling Code*, where specifically permitted by Chapters 11 through 43. These criteria permit the use of a public address system that is not part of an approved fire alarm system, provided that it has a secondary power supply and its audibility characteristics are such that announcements will be heard over the anticipated ambient noise in the occupancy. In addition, provisions must be made such that any emergency announcements will override the system's "normal" applications (for example, music or paging announcements). These criteria are based on criteria found in the assembly, mercantile, and business occupancy chapters prior to the 2009

edition. The provisions of 9.6.3.9.2 consolidated the criteria and made them available to be referenced by any occupancy chapter for subsequent *Code* editions.

It is the *Code's* intent that these alternative voice announcement occupant notification criteria are to be used in occupancies where the public address system is used routinely in the venue and, as a result, has an inherent high degree of reliability. An example of such a venue might be a sports arena in which the public address system is used to make announcements pertinent to the contest, and which has been designed to be heard over the expected crowd noise. The occupancies that permit the occupant notification arrangement described in 9.6.3.9.2 are the following:

1. Assembly occupancies (12.3.4.3.6, 13.3.4.3.6)
2. Mall buildings (36.4.4.7.3.1, 37.4.4.7.3.1)
3. Existing mercantile occupancies (37.3.4.3.1)
4. Existing bulk merchandising retail buildings (37.4.5.4.3)
5. Existing business occupancies (39.3.4.3)

**9.6.3.10** Unless otherwise permitted by another section of this *Code*, audible and visible fire alarm notification appliances shall comply with either 9.6.3.10.1 or 9.6.3.10.2.

An example of a use permitted by another section of the *Code*, as specified in 9.6.3.10, appears in 14.3.4.3.1.4 and 15.3.4.3.1.4 for educational occupancies; the fire alarm system is permitted to be used to designate class change, provided that the fire alarm signal is distinctively different from the class change signal and overrides all other use and provided that such arrangement is acceptable to the authority having jurisdiction.

**9.6.3.10.1** Audible and visible fire alarm notification appliances shall be used only for fire alarm system or other emergency purposes.

**9.6.3.10.2** Emergency voice/alarm communication systems shall be permitted to be used for other purposes in accordance with *NFPA 72, National Fire Alarm and Signaling Code*.

The provision of 9.6.3.10.2 permits a voice communication system to be used for some other purpose in accordance with *NFPA 72, National Fire Alarm and Signaling Code*. The system designer or building operator and the authority having jurisdiction should determine how susceptible the system is to deliberate tampering. For example, in a business occupancy where a combination emergency voice communication and daily background music system is installed with a speaker located in the ceiling directly over an employee's desk, it should be predicted that the constant background music might irritate the employee to the point that the speaker will be muffled or otherwise disabled. Therefore, the requirement that the fire alarm system take precedence over all other signals becomes futile; a disabled speaker cannot deliver the required emergency message.

## 9.6.4 Emergency Forces Notification.

**9.6.4.1** Where required by another section of this *Code*, emergency forces notification shall be provided to alert the municipal fire department and fire brigade (if provided) of fire or other emergency.

**9.6.4.2** Where emergency forces notification is required by another section of this *Code*, the fire alarm system shall be arranged to transmit the alarm automatically via any of the following means acceptable to the authority having jurisdiction and shall be in accordance with *NFPA 72, National Fire Alarm and Signaling Code*:

- (1) Auxiliary fire alarm system
- (2) Central station fire alarm system
- (3) Proprietary supervising station fire alarm system
- (4) Remote supervising station fire alarm system

Paragraphs 1 through 4, which follow, help differentiate among the four alarm transmission methods for fire department notification in 9.6.4.2.

**1. Auxiliary fire alarm system.** An auxiliary fire alarm system is a system connected to a municipal fire alarm system for transmitting a fire alarm to the public fire service communication center. Fire alarms from an auxiliary alarm system are received at the public fire service communication center on the same equipment and by the same methods as alarms transmitted manually from municipal fire alarm boxes located on streets.

**2. Central station fire alarm system.** A central station fire alarm system is a system or group of systems in which the operations of circuits and devices are signaled automatically to, recorded in, maintained by, and supervised from a listed central station staffed by competent and experienced servers and operators. Upon receipt of a signal, the staff takes such action as is required. Such service is controlled and operated by a person or firm whose business is the furnishing, maintaining, and monitoring of supervised fire alarm systems.

**3. Proprietary supervising station fire alarm system.** A proprietary supervising station fire alarm system is an installation of fire alarm systems that serves contiguous or noncontiguous properties under one ownership from a proprietary supervising station located at the protected property, where trained, competent personnel are in constant attendance. This system includes the proprietary supervising station; power supplies; signal initiating devices; initiating device circuits; signal notification appliances; equipment for the automatic, permanent, visual recording of signals; and equipment for initiating the operation of emergency building control services.

**4. Remote supervising station fire alarm system.** A remote supervising station fire alarm system is a system installed to transmit alarm, supervisory, and trouble signals from one or more protected premises to a remote supervising station location at which appropriate action is taken.

**9.6.4.3** For existing installations where none of the means of notification specified in 9.6.4.2(1) through (4) are available, an approved plan for notification of the municipal fire department shall be permitted.

The extensive availability of reliable communications systems has limited the necessity for the provision of 9.6.4.3 (formerly permitted for all occupancies) to existing installations only.

**9.6.4.4** For other than existing installations, where fire alarm systems are required to provide emergency forces notification, supervisory signals and trouble signals shall sound and be visibly displayed either at an approved, remotely located receiving facility or at a location within the protected building that is constantly attended by qualified personnel.

### 9.6.5 Fire Safety Functions.

**9.6.5.1** Fire safety functions shall be installed in accordance with the requirements of *NFPA 72, National Fire Alarm and Signaling Code*.

**9.6.5.2** Where required by another section of this *Code*, the following functions shall be actuated:

- (1) Release of hold-open devices for doors or other opening protectives

Doors are permitted by 7.2.1.8.2 to be automatic-closing if (among other requirements) the detection of smoke automatically releases the device holding the door open, thus allowing the door to become self-closing. The provisions of 7.2.1.8.2 do not require the building alarm system to release the doors. Chapters 18 and 19 for health care occupancies are more stringent on the subject and require that the automatic closing of doors must also occur upon initiation of the building's required fire alarm system (see 18.2.2.2.8 and 19.2.2.2.8). This is an example of an occupancy chapter mandating the application of 9.6.5.2(1) as a requirement that is needed in addition to the provisions of 7.2.1.8.2.

- (2) Stairwell or elevator shaft pressurization
- (3) Smoke management or smoke control systems

Manual fire alarm boxes generally should not be used to activate smoke control systems, other than stair tower pressurization systems, due to the likelihood of a person signaling an alarm from a location outside the smoke zone of fire origin. Such alarm initiation could put the smoke management system in an undesirable mode of operation and cause it to spread smoke from one zone to another, rather than restrict it. The installation of smoke control systems is addressed by *NFPA 92, Standard for Smoke Control Systems*.

- (4) Unlocking of doors

For an example of a *Code* requirement for the activation of the alarm system to unlock a door, see the provisions for delayed-egress door locking addressed by 7.2.1.6.1.

- (5) Elevator recall and shutdown

*ASME A17.1/CSA B44, Safety Code for Elevators and Escalators*, and *ASME A17.3, Safety Code for Existing Elevators and Escalators* (which are referenced mandatorily by Section 9.4), prohibit the recall of elevators by detectors, other than those installed in elevator lobbies, hoistways, and associated elevator machine rooms. Recall by other detectors can lead to numerous nuisance recalls under conditions where it would be safe to operate elevators. To avoid taking elevators out of service every time any building smoke detector activates, the recall feature is sometimes deliberately disabled. *ASME A17.1/CSA B44* and *ASME A17.3* impose the recall restriction to ensure the elevator recall feature remains operational. The elevator lobby, hoistway, and machine room detectors are permitted to be part of the building fire alarm system, provided that only the activation of those detectors initiates elevator recall.

- (6) HVAC shutdown

Requirements for automatic shutdown of heating, ventilating, and air-conditioning (HVAC) equipment upon detection of smoke are contained in *NFPA 90A, Standard for the Installation of Air-Conditioning and Ventilating Systems*. Where required, automatic HVAC shutdown can be accomplished by duct smoke detectors that are not part of a building fire alarm system. Alternatively, HVAC systems can be arranged to automatically shut down upon detection of smoke by open area smoke detectors that are connected to the building fire alarm system in accordance with *NFPA 72, National Fire Alarm and Signaling Code*. See *NFPA 72* and *NFPA 90A* for additional details.

In addition to the items listed in 9.6.5.2(1) through (6), fire alarm systems can be used to perform other fire safety control functions. For example, new special amusement buildings are addressed in 12.4.8. Those that operate in reduced lighting levels (e.g., a haunted house amusement) must, upon actuation of the required automatic smoke detection system or the required automatic sprinkler system, increase illumination in the means of egress to at least the minimum level required by Section 7.8. The requirements applicable to special amusement buildings augment the concept of using the alarm system to initiate an emergency control function by mandating that conflicting or confusing sounds and visual effects stop upon actuation of the required automatic smoke detection system or the required automatic sprinkler system. Thus, in a haunted house amusement, all audible and visual special effects would cease to operate upon alarm, so as not to confuse the patrons. A fire alarm horn or strobe might not be recognized if forced to compete with the background special effects common to such an occupancy.

**9.6.6 Location of Controls.** Operator controls, alarm indicators, and manual communications capability shall be installed at a convenient location acceptable to the authority having jurisdiction.

At times it is not practical, either physically or from a security standpoint, to locate fire alarm system controls adjacent to an entrance. For example, controls for proprietary fire alarm systems designed in accordance with *NFPA 72, National Fire Alarm and Signaling Code*, for reasons of security, often need to be located away from public areas. Thus, the *Code* does not require that controls be located adjacent to an entrance. However, because the controls are intended to be used by the fire department, they need to be located as approved by the authority having jurisdiction. Where the fire department does not serve as the AHJ, it should be consulted to determine an acceptable location.

## 9.6.7 Annunciation.

**Subsection 9.6.7** establishes provisions for fire alarm annunciation, which are then referenced by other sections of the *Code* as part of the overall life safety package needed for specific occupancies. Alarm annunciation allows trained individuals — such as building engineers, security and safety officers, and responding fire service personnel — to read the indicator lamps or alphanumeric displays of an annunciator panel to identify circuits, associated building locations, and conditions that warrant attention or investigation.

**9.6.7.1** Where alarm annunciation is required by another section of this *Code*, it shall comply with **9.6.7.2** through **9.6.7.8**.

**9.6.7.2** Alarm annunciation at the control center shall be by means of audible and visible indicators.

Alarm annunciation at the control center, as specified in **9.6.7.2**, must be by means of audible as well as visible indicators to capture the attention of the trained attendant, who might have numerous job functions within or near the control center that might distract attention from the annunciator panel. Where a control center is not required or otherwise provided, the annunciator panel should be located in or near a public space, such as an entrance lobby, so that trouble and supervisory signals will get the attention of a passerby, who can then notify the building's maintenance staff.

**9.6.7.3** For the purposes of alarm annunciation, each floor of the building, other than floors of existing buildings, shall be considered as not less than one zone, unless otherwise permitted by **9.6.7.4.4**, **9.6.7.4.5**, **9.6.7.4.6**, or another section of this *Code*.

**9.6.7.4** Where a floor area exceeds 22,500 ft<sup>2</sup> (2090 m<sup>2</sup>), additional fire alarm zoning shall be provided, and the length of any single fire alarm zone shall not exceed 300 ft (91 m) in any direction, except as provided in **9.6.7.4.1** through **9.6.7.4.6**, or as otherwise modified by another section of this *Code*.

**9.6.7.4.1** Where permitted by another section of this *Code*, fire alarm zones shall be permitted to exceed 22,500 ft<sup>2</sup> (2090 m<sup>2</sup>), and the length of a zone shall be permitted to exceed 300 ft (91 m) in any direction.

**9.6.7.4.2** Where the building is protected by an automatic sprinkler system in accordance with **9.7.1.1(1)**, the area of the fire alarm zone shall be permitted to coincide with the allowable area of the sprinkler system.

**9.6.7.4.3** Where the building is protected by a water mist system in accordance with **9.8.1** and **Table 9.8.1**, the area of the fire alarm zone shall be permitted to coincide with the allowable area of the water mist system.

**9.6.7.4.4** Unless otherwise prohibited by another section of this *Code*, where a building not exceeding four stories in height is protected by an automatic water mist system in accordance with **9.8.1**, the water mist system shall be permitted to be annunciated on the fire alarm system as a single zone.

**9.6.7.4.5** Unless otherwise prohibited by another section of this *Code*, where a building not exceeding four stories in height is protected by an automatic sprinkler system in accordance with **9.7.1.1(1)**, the sprinkler system shall be permitted to be annunciated on the fire alarm system as a single zone.

The provision of **9.6.7.4.5** permits the waterflow from a sprinkler system that meets NFPA 13, *Standard for the Installation of Sprinkler Systems*, to be annunciated as a single zone in buildings up to four stories in height, unless the applicable occupancy chapters prohibit such arrangement. Lacking this provision, sprinkler systems would have to be arranged so that every floor would be provided with a waterflow switch to permit each floor to be annunciated as separate zones. Such a requirement would limit the sprinkler system design flexibility and would prohibit the use of the so-called “birdcage” design in which multiple vertical risers act as loops for hydraulic efficiency. The only occupancy chapter that prohibits the use of **9.6.7.4.5** is **Chapter 18, New Health Care Occupancies** (see **18.3.4.3.3.3**).

**9.6.7.4.6** Where the building is protected by an automatic sprinkler system in accordance with **9.7.1.1(2)** or **9.7.1.1(3)**, the sprinkler system shall be permitted to be annunciated on the fire alarm system as a single zone.

**Paragraphs 9.6.7.4.1** through **9.6.7.4.6** provide a choice of zone locations and zone sizes for meaningful annunciation. In a new, multiple-story building required to have alarm annunciation by another section of the *Code*, **9.6.7.3** would not permit two or more floors to be considered as a single zone, unless the building were a residential occupancy sprinklered in accordance with NFPA 13R, *Standard for the Installation of Sprinkler Systems in Low-Rise Residential Occupancies*,<sup>19</sup> NFPA 13D, *Standard for the Installation of Sprinkler Systems in One- and Two-Family Dwellings and Manufactured Homes*,<sup>20</sup> or as otherwise permitted by **9.6.7.4.5**, in which case the sprinkler system would be permitted to be annunciated as a single zone. In buildings other than those sprinklered in accordance with NFPA 13, *Standard for the Installation of Sprinkler Systems* (up to four stories, other than new health care), NFPA 13R, or NFPA 13D, floors must be annunciated

separately; otherwise an alarm condition would be annunciated as originating in a zone that includes multiple floors and, thus, would not identify the specific location of the fire. Such a situation might delay the investigation and associated emergency response effort. Existing alarm annunciation systems are exempted from the requirement of 9.6.7.3, so as not to unfairly render existing Code-complying installations abruptly noncompliant, thereby avoiding the need for major alterations or a complete replacement of the alarm system.

Residential sprinkler systems in accordance with NFPA 13R and NFPA 13D commonly utilize a so-called “birdcage” piping configuration in which the sprinkler branch lines are run vertically through the building, rather than horizontally, providing an economical design alternative. (The resulting piping network resembles a birdcage, thus the name.) With such a configuration, however, it is not practical to provide waterflow devices for every floor, since each branch line typically serves multiple floors. Therefore, a single waterflow device is provided on the supply piping ahead of the branch lines, resulting in the sprinkler system being annunciated as a single zone. Although such an arrangement might increase the time required for emergency responders to locate the fire, it is considered a reasonable alternative for residential occupancies not exceeding four stories in height utilizing sprinkler systems compliant with NFPA 13R or NFPA 13D.

It is further specified in 9.6.7.4 that no one zone, for alarm annunciation purposes, even if located entirely on one floor of the building, is permitted to be so large that it delays identification of the location from which the alarm was initiated. The permitted zone size, 22,500 ft<sup>2</sup> (2090 m<sup>2</sup>), is intended to coordinate with the maximum permitted smoke compartment size in health care and detention and correctional occupancies. The maximum zone area and zone dimensional criteria are modified by 9.6.7.4.2 for fully sprinklered buildings, allowing the alarm system zoning to coincide with the area of the sprinkler system zone. Depending on the sprinkler system’s design, this might result in a zone as large as 52,000 ft<sup>2</sup> (4831 m<sup>2</sup>). This requirement helps to achieve consistency in reporting alarms from signaling system devices and from sprinkler system waterflow to the alarm annunciator. Although a sprinkler system might be designed and installed by parties other than those who design and install fire alarm systems, the coordination of these two systems is needed during the design phase to ensure that they complement each other.

**9.6.7.5** A system trouble signal shall be annunciated by means of audible and visible indicators in accordance with NFPA 72, *National Fire Alarm and Signaling Code*.

**9.6.7.6** A system supervisory signal shall be annunciated by means of audible and visible indicators in accordance with NFPA 72, *National Fire Alarm and Signaling Code*.

Alarm system trouble signals and supervisory signals must be annunciated by both audible and visible indicators in accordance

with 9.6.7.5 and 9.6.7.6 to help ensure that personnel will respond to the indication. Trouble signals indicate such conditions as a circuit break or ground occurring in the fire alarm system wiring. Supervisory signals indicate conditions that would adversely affect the operation of a fire suppression system, such as a closed control valve on an automatic sprinkler system. Supervisory signals can also be associated with the supervision of other extinguishing systems and equipment.

**9.6.7.7** Where the system serves more than one building, each building shall be annunciated separately.

**9.6.7.8** Where permitted by another section of this Code, the alarm zone shall be permitted to coincide with the permitted area for smoke compartments.

## 9.7 Automatic Sprinklers

### 9.7.1 General.

**9.7.1.1\*** Each automatic sprinkler system required by another section of this Code shall be in accordance with one of the following:

- (1) NFPA 13, *Standard for the Installation of Sprinkler Systems*
- (2) NFPA 13D, *Standard for the Installation of Sprinkler Systems in One- and Two-Family Dwellings and Manufactured Homes*
- (3) NFPA 13R, *Standard for the Installation of Sprinkler Systems in Low-Rise Residential Occupancies*

**A.9.7.1.1** For a discussion of the effectiveness of automatic sprinklers, as well as a general discussion of automatic sprinklers, see the NFPA *Fire Protection Handbook*. Where partial sprinkler protection is permitted by another section of this Code, the limited area systems provisions of NFPA 13, *Standard for the Installation of Sprinkler Systems*, should apply.

The Code requirements for automatic sprinklers are based on the sprinkler experience record, which shows that, where installed properly, an automatic sprinkler system is the most effective tool for protecting and safeguarding against loss of life and property. Occupants of a building who are aware of the presence of sprinkler protection can feel secure that any fire will be detected and extinguished or controlled at its origin.

Numerous myths exist regarding the operation of automatic sprinklers. Some are reinforced by misrepresentations in the news media or the entertainment industry. The following facts should serve to debunk these myths:

1. Sprinkler systems do not typically operate when smoke or other fire detectors operate (the relatively rare exception being deluge-type systems for the protection of special hazards).

2. All sprinklers in the building do not operate simultaneously, unless specifically designed to do so (e.g., deluge systems).
3. Sprinklers do not spray water that has been superheated by the fire, resulting in the scalding of building occupants.
4. Sprinkler system operation does not cause drowning or electrocution of building occupants.
5. Sprinkler system operation does not increase the amount of smoke generated by the fire; rather, it significantly reduces the generation of smoke and other hazardous products of combustion.

Automatic sprinkler systems remain the single most effective means of controlling fire spread for the widest range of buildings and areas. It is for this reason that the *Code* permits the relaxation of many of its requirements where automatic sprinklers are present.

NFPA 13, *Standard for the Installation of Sprinkler Systems*, covers installation details for automatic sprinkler systems. In the interest of both life safety from fire and the protection of property, it is generally beneficial to provide a complete automatic sprinkler system to protect the entire building. Automatic sprinklers can be beneficial even in situations where the *Code* requires them only in limited areas for the protection of hazardous contents.

NFPA 13 is the authoritative source for automatic sprinkler systems with respect to design, installation, and character and adequacy of water supply. Even though there are usually some areas in a building where fires are more likely to start than others, it is impossible to predict with absolute certainty where a fire might start and protect only those areas. Thus, where sprinklers are installed, they should be installed throughout a building. The basic requirements of NFPA 13 for spacing, locating, and positioning sprinklers are based on principles that include sprinkler installation throughout the building — including combustibles concealed spaces. The *Life Safety Code*, however, in an effort to promote the use of sprinkler systems by reducing the costs, permits sprinklers to be omitted from small closets and bathrooms in various residential occupancies but considers those occupancies to be fully sprinklered. For an example, see 29.3.5.5, which applies to existing hotels and dormitories.

NFPA 13D, *Standard for the Installation of Sprinkler Systems in One- and Two-Family Dwellings and Manufactured Homes*, was developed following extensive research that included full-scale fire tests. NFPA 13D introduced the concept of a quick-response residential sprinkler. Unlike its standard spray sprinkler counterpart, a quick-response residential sprinkler operates relatively quickly once its rated temperature is reached, whereas a standard response sprinkler takes longer to activate because of its greater thermal mass. It begins controlling a fire early in its growth. In addition to being quick to respond, residential sprinklers have a specifically designed spray pattern that delivers water to nearly the full height of the walls of small rooms that are characteristic of residential occupancies.

NFPA 13R, *Standard for the Installation of Sprinkler Systems in Low-Rise Residential Occupancies*, was first published in 1989. NFPA 13R extends the technological and economic benefits of an NFPA 13D-type system to larger residential buildings, while mandating additional requirements that are commensurate with increased building size. The requirements help to ensure improved protection against injury and life loss to building occupants, including those within the room of fire origin.

NFPA 25, *Standard for the Inspection, Testing, and Maintenance of Water-Based Fire Protection Systems*,<sup>21</sup> provides information on required maintenance procedures for automatic sprinkler systems.

**9.7.1.2** Sprinkler piping serving not more than six sprinklers for any hazardous area shall be permitted to be connected directly to a domestic water supply system having a capacity sufficient to provide 0.15 gpm/ft<sup>2</sup> (6.1 mm/min) throughout the entire enclosed area.

**9.7.1.3** Sprinkler piping serving hazardous areas as described in 9.7.1.2 shall be provided with an indicating shutoff valve, supervised in accordance with 9.7.2 or NFPA 13, *Standard for the Installation of Sprinkler Systems*, and installed in an accessible, visible location between the sprinklers and the connection to the domestic water supply.

The general provisions of Section 8.7 for special hazard protection — in combination with the specific requirements of the \_\_\_3.2 subsection of each occupancy chapter — make extensive use of sprinklering hazardous contents rooms in otherwise nonsprinklered buildings. Such sprinklers are permitted by 9.7.1.2 to be supplied by the domestic water supply and its associated distribution piping. The domestic water supply must provide a sufficient volume of water at the appropriate pressure to deliver a sprinkler discharge density of 0.15 gpm/ft<sup>2</sup> (6.1 mm/min) within the hazardous contents room. For a 100 ft<sup>2</sup> (9.3 m<sup>2</sup>) room, the water supply would have to provide at least 15 gpm (57 L/min) at the pressure appropriate to such a discharge from a specific size and model of sprinkler. Additionally, the provisions of 9.7.1.2 can be used (in lieu of a devoted sprinkler system piping network and water supply) only if any given room requires six or fewer sprinklers for adequate protection, based on the spacing and location rules of the applicable installation standards referenced in 9.7.1.1. Another hazardous contents room on the same floor, or in some other part of the building, can obtain its protection by repeating a similar maximum six-sprinkler installation in accordance with 9.7.1.2 and 9.7.1.3.

**9.7.1.4\*** In areas protected by automatic sprinklers, automatic heat-detection devices required by other sections of this *Code* shall not be required.

**A.9.7.1.4** Properly designed automatic sprinkler systems provide the dual function of both automatic alarms and automatic extinguishment. Dual function is not provided in those cases where

early detection of incipient fire and early notification of occupants are needed to initiate actions in behalf of life safety earlier than can be expected from heat-sensitive fire detectors.

Because the operation of an automatic sprinkler system is initiated by a heat-sensing element and works on the same principle as an automatic heat detection and alarm system, a sprinkler system is judged to be capable of serving the same purpose. Even though some sprinkler systems do not sound an alarm on activation, many do. Furthermore, although a particular sprinkler system might not sound an alarm, it does immediately initiate extinguishment; this is a feature that is at least as valuable, if not more so, than a system that sounds an alarm only.

Detection of smoke, on the other hand, can be accomplished at the incipient stages of a fire and can give rise to an earlier warning than that provided by heat detection, so smoke detection is considered in a somewhat different light. One school of thought is that a system that starts suppression of a fire immediately upon detection is better than one that simply detects the fire and sounds an alarm, even though the latter can be quicker to initiate an alarm signal. Others believe, however, that an early alarm is more advantageous. The first group is concerned with the immediate suppression or containment of fire; it might take considerable time for fire fighters to arrive. The second group stresses immediate notification of occupants. The *Code* recognizes the value of both strategies, and strives for a balanced approach to occupant protection by requiring, in some occupancies, both early warning and automatic suppression systems, depending on the characteristics of the occupants. The extent of protection provided should be commensurate with the ability of the occupants to evacuate or relocate to a safe location within the building before the egress routes are compromised by the effects of a fire.

**9.7.1.5** Automatic sprinkler systems installed to make use of an alternative permitted by this *Code* shall be considered required systems and shall meet the provisions of this *Code* that apply to required systems.

The provisions of **9.7.1.5** specify that an automatic sprinkler system voluntarily installed as a *Code* alternative is considered a required system; therefore, it is subject to the same requirements (including maintenance) that apply to a sprinkler system specifically mandated by the *Code*. For example, if an occupancy that does not require a sprinkler system permits the use of the delayed-egress door locking system addressed by **7.2.1.6.1**, and if the designer or building operator meets one of the unlocking provisions of **7.2.1.6.1** via the installation of an approved, supervised automatic sprinkler system, the sprinkler system is considered a required system. Therefore, the system must meet all requirements that apply to a similar system installed to comply with the *Code* in addition to those of the alternative system, such as delayed-egress door locking.

## 9.7.2 Supervision.

Automatic sprinkler system supervision is not required by **9.7.2**. Rather, the requirements of **9.7.2** apply where a supervised automatic sprinkler system is mandated by another section of the *Code*. Most of the occupancy chapters that require an automatic sprinkler system for life safety purposes also require the system to be electrically supervised in accordance with **9.7.2**.

### 9.7.2.1\* Supervisory Signals.

**A.9.7.2.1** *NFPA 72, National Fire Alarm and Signaling Code*, provides details of standard practice in sprinkler supervision. Subject to the approval of the authority having jurisdiction, sprinkler supervision is also permitted to be provided by direct connection to municipal fire departments or, in the case of very large establishments, to a private headquarters providing similar functions. *NFPA 72* covers such matters. System components and parameters that are required to be monitored should include, but should not be limited to, control valves, water tank levels and temperatures, tank pressure, and air pressure on dry-pipe valves.

Where municipal fire alarm systems are involved, reference should also be made to *NFPA 1221, Standard for the Installation, Maintenance, and Use of Emergency Services Communications Systems*.

**9.7.2.1.1** Where supervised automatic sprinkler systems are required by another section of this *Code*, supervisory attachments shall be installed and monitored for integrity in accordance with *NFPA 72, National Fire Alarm and Signaling Code*, and a distinctive supervisory signal shall be provided to indicate a condition that would impair the satisfactory operation of the sprinkler system.

**9.7.2.1.2** Supervisory signals shall sound and shall be displayed either at a location within the protected building that is constantly attended by qualified personnel or at an approved, remotely located receiving facility.

One reason why the automatic sprinkler system has attained a high level of satisfactory performance and response to fire conditions is that, through supervision, it can be kept in operative condition. Of course, keeping the system operative depends on routine maintenance and the owner's willingness to repair the system when there are indications of impairment. Features of the system, such as the following, can be automatically monitored:

1. Opening and closing of water control valves
2. Power supplies for required fire pumps
3. Water tank level

If an undesirable situation develops, a signal is annunciated in the protected building or relayed to a monitoring facility.

A supervisory system will also indicate or activate a water-flow alarm. In addition to being transmitted to an alarm-

monitoring agency, the waterflow alarm can be transmitted directly to the fire department. The signals for electrical and mechanical problems need not burden the fire department unnecessarily, yet those indicating a fire can be received directly.

### 9.7.2.2 Alarm Signal Transmission.

**9.7.2.2.1** Where supervision of automatic sprinkler systems is required by another section of this *Code*, waterflow alarms shall be transmitted to an approved, proprietary alarm-receiving facility, a remote station, a central station, or the fire department.

**9.7.2.2.2** The connection described in **9.7.2.2.1** shall be in accordance with **9.6.1.3**.

## 9.8 Other Automatic Extinguishing Equipment

**9.8.1\* Alternative Systems.** In any occupancy where the character of the fuel for fire is such that extinguishment or control of fire is accomplished by a type of automatic extinguishing system in lieu of an automatic sprinkler system, such extinguishing system shall be installed in accordance with the applicable standard referenced in **Table 9.8.1**.

**A.9.8.1** There are typically two different ways that extinguishing systems other than fire sprinkler systems are used. The first is when the entire building is protected with one of these alternate systems. When this is the case, the exceptions, reductions, and alternative code provisions that are offered as options when fire sprinkler systems are installed should not be granted to the other extinguishing system unless the other system has demonstrated the same temperature control during a fire and reliability of

operation as a fire sprinkler system. Reliability of operation needs to extend to the long-term use of the other system and an analysis of the reliability of the component parts. Some component of other extinguishing systems can show reliability data from their use in systems outside of fire protection where they get exercised on a regular basis, but acceptance on this basis is cautioned because many mechanical parts that sit for a long time without being exercised, as fire protection systems need to do, might not have the same reliability. A reliability analysis should also take into account inspection, testing, and maintenance criteria and the likelihood of a building owner knowing and understanding what needs to be performed to keep the other system operational.

The second manner in which other systems are used as alternatives to fire sprinkler systems are in individual rooms or spaces of otherwise sprinklered occupancies. Here the authority having jurisdiction needs to use some judgment in the application of exceptions, reductions, and alternative code provisions that are offered for sprinklered occupancies. The permission to utilize such exceptions, reductions, and alternative code provisions far from the space with the other fire protection system should be granted. Closer to the space with the alternate system, exceptions, reductions, and alternate code provisions for sprinklers could be granted if the system was analyzed as discussed above and found to be equivalent to a fire sprinkler system.

*Use of special types of extinguishing systems is a matter of engineering judgment on the part of the designer, working in collaboration with the owner and the authority having jurisdiction. For example, it might be undesirable to install automatic sprinklers in a portion of a facility used for storage of water-reactive materials, such as magnesium. The application of water to such materials can significantly exacerbate a fire problem.*

**Table 9.8.1 Fire Suppression System Installation Standards**

Fire Suppression System	Installation Standard
Low-, medium-, and high-expansion foam systems	NFPA 11, <i>Standard for Low-, Medium-, and High-Expansion Foam</i>
Carbon dioxide systems	NFPA 12, <i>Standard on Carbon Dioxide Extinguishing Systems</i>
Halon 1301 systems	NFPA 12A, <i>Standard on Halon 1301 Fire Extinguishing Systems</i>
Water spray fixed systems	NFPA 15, <i>Standard for Water Spray Fixed Systems for Fire Protection</i>
Deluge foam-water sprinkler systems	NFPA 16, <i>Standard for the Installation of Foam-Water Sprinkler and Foam-Water Spray Systems</i>
Dry chemical systems	NFPA 17, <i>Standard for Dry Chemical Extinguishing Systems</i>
Wet chemical systems	NFPA 17A, <i>Standard for Wet Chemical Extinguishing Systems</i>
Water mist systems	NFPA 750, <i>Standard on Water Mist Fire Protection Systems</i>
Clean agent extinguishing systems	NFPA 2001, <i>Standard on Clean Agent Fire Extinguishing Systems</i>

It is not the intent of 9.8.1 to permit a required sprinkler system to be replaced by a gaseous suppression system in a portion of a building where the application of water might be harmful to the building contents or equipment (e.g., computer or telecommunications equipment). To be effective, such systems typically depend on a limited quantity of extinguishing agent, and the protected room must be essentially airtight to allow the extinguishing agent concentration to remain sufficiently high for the time necessary to extinguish the fire. If the room enclosure is penetrated and not properly sealed, or if a door is propped open, the extinguishing system might not function as intended, and once the system discharges its extinguishing agent, there is typically no backup agent. Where a sprinkler system is required and there is concern about the application of water to the contents or equipment for reasons other than the ability of water to control or extinguish a fire involving such contents, an area could be protected by both a gaseous extinguishing system and an automatic sprinkler system; the special system will serve as a first line of defense in the event of a fire, and, if it fails to extinguish the fire for whatever reason, the sprinkler system will activate. If there is concern about accidental activation of a sprinkler system, a preaction system can be installed whereby the sprinkler piping is not filled with water until an automatic detection system senses smoke or fire in the room. Even then, water will not be discharged from the system unless a sprinkler reaches its design activation temperature.

The NFPA standards listed in Table 9.8.1 provide mandatory requirements for the installation and maintenance of such special types of extinguishing systems.

## 9.8.2 Alarm Activation.

**9.8.2.1** If the extinguishing system is installed in lieu of a required, supervised automatic sprinkler system, the activation of the extinguishing system shall activate the building fire alarm system, where provided.

**9.8.2.2** The actuation of an extinguishing system that is not installed in lieu of a required, supervised automatic sprinkler system shall be indicated at the building fire alarm system, where provided.

**9.8.2.3** In areas protected by an automatic water mist system, automatic heat-detection devices required by other sections of this Code shall not be required.

The activation of a special extinguishing system — installed in lieu of a required supervised automatic sprinkler system — must activate the building fire alarm system where provided per 9.8.2.1. This system provides early warning to building occupants so that necessary action, probably evacuation, can occur. If the special extinguishing system is not serving as a substitute for the required supervised automatic sprinkler system, its activation need only be indicated at the fire alarm control unit or remote annunciator in accordance with 9.8.2.2.

A kitchen exhaust hood and duct extinguishing system is an example of a special extinguishing system not serving as a substitute for a required supervised automatic sprinkler system. The operation of a kitchen exhaust hood and duct extinguishing system would have to be indicated at the fire alarm panel, but would not have to result in the activation of audible and visible occupant notification signals unless specifically required by the applicable occupancy chapter.

---

## 9.9\* Portable Fire Extinguishers

Where required by another section of this Code, portable fire extinguishers shall be selected, installed, inspected, and maintained in accordance with NFPA 10, *Standard for Portable Fire Extinguishers*.

**A.9.9** For a description of standard types of extinguishers and their installation, maintenance, and use, see NFPA 10, *Standard for Portable Fire Extinguishers*. The labels of recognized testing laboratories on extinguishers provide evidence of tests indicating the reliability and suitability of the extinguisher for its intended use. Many unlabeled extinguishers are offered for sale that are substandard by reason of insufficient extinguishing capacity, questionable reliability, or ineffective extinguishing agents for fires in ordinary combustible materials or because they pose a personal hazard to the user.

Portable fire extinguishers are required throughout health care, ambulatory health care, detention and correctional, new large board and care, mercantile, and business occupancies, but only in the hazardous areas of nonsprinklered hotels and dormitories, nonsprinklered apartment buildings, and existing large board and care occupancies. Where the Code requires portable fire extinguishers, the number, types, and locations required can be found in NFPA 10, *Standard for Portable Fire Extinguishers*.<sup>22</sup>

---

## 9.10 Standpipe Systems

**9.10.1** Where required by another section of this Code, standpipe and hose systems shall be provided in accordance with NFPA 14, *Standard for the Installation of Standpipe and Hose Systems*.

**9.10.2** Where standpipe and hose systems are installed in combination with automatic sprinkler systems, installation shall be in accordance with the appropriate provisions established by NFPA 13, *Standard for the Installation of Sprinkler Systems*, and NFPA 14, *Standard for the Installation of Standpipe and Hose Systems*.

The Code requires standpipe systems only in certain occupancy chapters. For example, standpipes are required on stages of

assembly occupancies and in detention and correctional occupancies. Standpipe provisions also appear as part of the Section 11.8 provisions applicable to high-rise buildings (see 11.8.3.2).

---

## 9.11 Fire Protection System Operating Features

**9.11.1 Maintenance and Testing.** All automatic sprinkler and standpipe systems required by this *Code* shall be inspected, tested, and maintained in accordance with NFPA 25, *Standard for the Inspection, Testing, and Maintenance of Water-Based Fire Protection Systems*.

**9.11.2 Sprinkler System Impairments.** Sprinkler impairment procedures shall comply with NFPA 25, *Standard for the Inspection, Testing, and Maintenance of Water-Based Fire Protection Systems*.

A sprinkler system might be shut down for any number of reasons during the life of a building. Some shutdowns are preplanned, controlled, and of short duration, such as those during periodic testing and maintenance. Others might be preplanned and of longer duration, such as shutdowns during times of building or system renovation. Emergency shutdown of the system can be the result of fire or other physical damage and might result in a short or lengthy shutdown to repair the system. Advance planning should help ensure that the system, or most of the system, can be restored to service, despite the scope of the renovation or the extent of an unexpected impairment. If the sprinkler system is required by the *Code*, or if it was installed to make use of one of the alternatives offered by the *Code*, it must be in operable condition for the building to be considered *Code* compliant.

Prior to the 2012 edition, the *Code* mandated notification of the AHJ, and evacuation of the building or provision of an approved fire watch any time a required automatic sprinkler system was out of service for more than 4 hours in a 24-hour period. In the 2012 and current editions, rather than providing prescriptive requirements, the *Code* references the automatic sprinkler system impairment procedures of NFPA 25, *Standard for the Inspection, Testing, and Maintenance of Water-Based Fire Protection Systems*.

NFPA 25 requires the building owner or designated representative to assign an impairment coordinator who is responsible for compliance with the impairment requirements. Designation of an individual as responsible for any system impairments increases the probability that the system will be returned to service in a timely manner. NFPA 25 further specifies that, where a required water-based fire protection system is out of service for more than 10 hours (rather than 4 hours as specified in previous

editions of the *Code*) during a 24-hour period, the impairment coordinator must arrange for one of the following:

1. Evacuation of the building or portion of the building affected by the system out of service
2. Establishment of an approved fire watch
3. Establishment of a temporary water supply
4. Establishment and implementation of an approved program to eliminate potential ignition sources and limit the amount of fuel available to the fire

In addition, the impairment coordinator is responsible for ensuring the fire department is notified of any system impairment, regardless of the duration. Likewise, the fire department must be notified when the system is returned to service. Fire department notification of automatic sprinkler system impairments is crucial, because fire-fighting tactics will vary, depending on the presence of an operational system or lack thereof.

Where a fire watch is provided to meet the impairment requirements of NFPA 25, it is the intent of the *Code* that the fire watch result in a heightened awareness of the building's operations and environment. Individuals assigned to the fire watch should be able to recognize fire hazards and understand the procedures for occupant and fire department notification and occupant evacuation in an emergency.

When developing a plan to address system shutdown, it is important to consider the nature of the shutdown, the location, the increased hazards that are involved, and the actions necessary to mitigate the hazards. The authority having jurisdiction should be involved in the development of these plans.

A parallel requirement in 9.6.1.5 addresses fire alarm system impairments.

### 9.11.3 Documentation.

**9.11.3.1** All required documentation regarding the design of the fire protection system and the procedures for maintenance, inspection, and testing of the fire protection system shall be maintained at an approved, secured location for the life of the fire protection system.

**9.11.3.2** Testing and maintenance records required by NFPA 25, *Standard for the Inspection, Testing, and Maintenance of Water-Based Fire Protection Systems*, shall be maintained at an approved, secured location.

---

## 9.12 Carbon Monoxide (CO) Detection and Warning Equipment

Where required by another section of this *Code*, carbon monoxide (CO) detection and warning equipment shall be provided in accordance with NFPA 720, *Standard for the Installation of Carbon Monoxide (CO) Detection and Warning Equipment*.

Section 9.12 provides a reference to NFPA 720, *Standard for the Installation of Carbon Monoxide (CO) Detection and Warning Equipment*, where such equipment is mandated by another section of the *Code*. It is noted that not all occupancies are required to be provided with CO detection and warning equipment. Such equipment is not currently required by the *Code* to be installed in any existing occupancy; its use is generally limited to new occupancies (other than certain existing health care occupancies) in which occupants might be asleep or otherwise have decreased capability of self-preservation and where vehicles, combustion equipment, or appliances are present. The occupancies requiring CO detection and warning equipment are as follows:

1. New educational occupancies (14.3.4.4)
2. New day-care homes (16.6.3.4.5)
3. New and existing health care occupancies containing fireplaces (18.5.2.3 and 19.5.2.3)
4. New one- and two-family dwellings (24.3.4.2)
5. New lodging or rooming houses (26.3.4.6)
6. New hotels and dormitories (28.3.4.6)
7. New apartment buildings (30.3.4.6)

Exhibit 9.16 is an example of a CO alarm. It is important to note that all CO detectors and alarms have a limited service life — typically about 5 to 10 years. CO detection equipment must be replaced at the end of its service life; the recommended replacement date is required by NFPA 720 to be marked on the device.

The requirements for CO detection and warning equipment are not based on safety to life from fire considerations. Rather,

they are intended to mitigate the risk to building occupants posed by exposure to CO gas, which is a natural product of incomplete combustion of hydrocarbon fuels. Where combustion gases from equipment in a building (such as a fuel-fired furnace) are not properly vented, or where CO gas infiltrates a building from a space such as an attached garage, occupants are at risk of CO poisoning. CO gas is sometimes referred to as the “silent killer” because it is colorless and odorless. Without CO detection and warning equipment, its presence is virtually impossible to detect.

According to the Centers for Disease Control and Prevention (CDC)<sup>23</sup>, approximately 15,200 people were treated annually from 2001 to 2003 in emergency departments for unintentional, non-fire-related CO exposure. During 2001 to 2002, an estimated 480 people died annually as a result of such exposure. In 2005, municipal fire departments responded to an estimated 61,100 non-fire CO incidents where CO was present.<sup>24</sup> The cold weather months of January and December are the peak months for non-fire CO incidents, and 89 percent of non-fire CO incidents took place in the home.

NFPA 720 is formatted much like NFPA 72, *National Fire Alarm and Signaling Code*, and contains requirements for CO detection systems (analogous to fire alarm systems), as well as single- and multiple-station CO alarms (analogous to smoke alarms). It was first published in 1998 under the title *Recommended Practice for the Installation of Household Carbon Monoxide (CO) Warning Equipment*. In 2005, it was revised as a standard; however, its scope was still limited to dwelling units. For the 2009 edition, the scope of NFPA 720 was significantly expanded to include occupancies other than residential dwelling units. The expanded requirements were based on the Fire Protection Research Foundation report *Development of a Technical Basis for Carbon Monoxide Detector Siting Research Project*.<sup>25</sup> Where NFPA 720 is applied via adoption of the *Life Safety Code*, and where the occupancy chapter requirements of this *Code* differ from the requirements of NFPA 720, the requirements of this *Code* should apply. Where both this *Code* and NFPA 720 are separately adopted and enforced, the more stringent requirements should be followed so as to meet the minimum requirements of both documents.

Exhibit 9.16

Carbon monoxide alarm. (© Danny Hooks, Dreamstime.com)

## 9.13 Special Inspections and Tests

**9.13.1 System Verification.** Where required by another section of this *Code*, special inspections and tests shall be performed to verify the operation of the fire protection system in its final condition for acceptance by the authority having jurisdiction.

**9.13.2 Experience.** The special inspector’s relevant experience in the design, installation, and testing of the fire protection systems shall be documented.

**9.13.3 Documentation.** The design documents shall provide the procedures and methods to be used and items subject to special inspections and tests.

**9.13.4 Report.** The special inspector shall submit an inspection and test report to the authority having jurisdiction and registered design professional (RDP) in responsible charge.

**Section 9.13** recognizes the complex nature of certain life safety systems in buildings. Where required by another section of the *Code*, special inspections must be performed, and design and test documentation must be provided to the authority having jurisdiction to ensure the system will perform as intended during a fire. Currently, only engineered smoke management systems must be submitted to special inspections and tests, as required by **9.3.3**, to ensure all relevant parties (building owner's representative, design professional, and AHJ) understand the goals and objectives of the system (e.g., to maintain the means of egress tenable for a given time period to facilitate evacuation) and the required performance criteria needed to achieve the stated goals (e.g., the pressure differences needed between smoke zones and other performance criteria). See NFPA 92, *Standard for Smoke Control Systems*, for additional details on smoke control system design.

# Interior Finish, Contents, and Furnishings

Historically, many fire fatalities have been attributed to the quick spread of fire. Often the fire spread occurs along the expanses of exposed wall and ceiling coverings and via the contents of the building. Such was the case with The Station nightclub fire in West Warwick, Rhode Island, in February 2003. In that fire, pyrotechnics ignited acoustical foam wall and ceiling surfaces, resulting in a rapidly developing fire and the deaths of 100 people.

**Chapter 10** establishes basic requirements for interior wall, ceiling, and floor finish and for furnishings and contents. This chapter specifies a menu of protection options, which are mandated to varying degrees by the occupancy chapters. However, some of the requirements of this chapter apply to all occupancies.

**Section 10.2** provides requirements for interior finish, which includes wall, ceiling, and floor finishes. The concept behind the requirements is to slow the flame spread across these finish surfaces to allow additional time for occupants to relocate within, or evacuate from, a building. The fire characteristics of interior finish can play a dramatic role in life safety when a fire occurs.

**Section 10.3** addresses the contents and furnishings in a building. Where provisions of this section are formatted so as to apply to any occupancy unless specifically exempted, many occupancy chapters provide such exemptions. The occupancies for which the regulation of furnishings and contents is part of the overall life safety scheme involve occupants who are nonambulatory, who are otherwise restrained or detained, or who are asleep. Contrast this application with the provisions for interior finish that are mandated by all of the occupancy chapters.

## 10.1 General

Interior finish has been a significant factor in rapid flame spread in many of the deadliest U.S. fires of recent decades. The paragraphs that follow describe a few examples of such fires.

In June 1989, five people died on the floor of origin of an “intense, rapidly developing fire on the sixth floor of an office building” in Atlanta, Georgia.<sup>1</sup> In this fire, “. . . the fire spread was so fast that the blaze in the corridor had burned itself out by the time fire fighters entered the sixth floor about seven minutes after the initial alarm . . . This is not the first time that multiple layers of wall coverings have been identified as a contributing factor in a fire . . . It is evident that this condition existed in the Atlanta building, that the materials in those layers contributed to the total load in the corridor, and that it is likely they contributed to the rate of fire spread.”

**Exhibit 10.1**

*Dupont Plaza Hotel Fire, in which rapid fire growth was, in part, due to wall finish in room of origin.*

Regarding the 1986 Dupont Plaza Hotel fire (see **Exhibit 10.1**) in which 96 people died: “Under the NFPA *Life Safety Code*, interior finish in all ballrooms, including the room of origin, should have been Class A or Class B. The wall finish of the room of origin contributed to the rapid fire growth.”<sup>2</sup>

In the 1981 Las Vegas Hilton Hotel fire, combustible carpeting on the walls and ceilings of elevator lobbies contributed to horizontal fire spread on the floor of origin and vertical spread involving 22 floors. Eight people died.<sup>3</sup>

In a 1978 Holiday Inn fire that killed 10 people, “lightweight plywood paneling in stairway did not meet *Life Safety Code*, was involved early in fire, and produced rapid growth and spread.” In a 1979 Holiday Inn fire that also killed 10 people, “carpeting and some wall covering in corridors had excessively high flame-spread properties.”<sup>4</sup>

In a 1972 Springfield, Illinois, convalescent nursing home fire that killed 10 of the 41 patients, “the wood-panel finish accelerated fire spread . . . Combustible interior finish — especially interior finish such as the wood paneling in this facility — should not be allowed where infirm people are housed . . . The paneling on the stairway had completely burned away, permitting fire spread into the first floor through holes in the plaster.”<sup>5</sup>

Regarding the 1970 Pioneer International Hotel fire where 28 died:

Corridors and stairs were carpeted (100 percent acrylic), with two layers of padding under carpet in corridors and carpeting extending 22 inches up the walls. Above

the carpeted areas of the wall were sections of wood, wallpaper, and plastic-laminated plywood. Interior finish contributed to fire.<sup>6</sup>

**10.1.1 Application.** The interior finish, contents, and furnishings provisions set forth in this chapter shall apply to new construction and existing buildings.

Highly combustible interior wall and ceiling finishes and easily ignited contents and furnishings are repeatedly reported as factors in fire spread in various occupancies. The frequent contribution of these factors to fire spread demonstrates the need to apply Chapter 10 requirements to both new and existing occupancies.

**10.1.2 Automatic Sprinkler Systems.** Where another provision of this chapter requires an automatic sprinkler system, the automatic sprinkler system shall be installed in accordance with the subparts of 9.7.1.1 as permitted by the applicable occupancy chapter.

The protection provided by automatic sprinklers, especially with respect to preventing flashover (see 3.3.114), is recognized via certain exemptions in Chapter 10. For example, in locations protected by automatic sprinklers, 10.2.8.1 permits the use of Class C interior wall and ceiling finish materials where Class B would otherwise be required. It is important that the sprinkler system be designed and installed in accordance with the proper standard. Subsection 10.1.2 relegates the appropriate sprinkler system installation standard to the applicable occupancy chapter. For example, sprinkler systems required for new health care occupancies must be installed per NFPA 13, *Standard for the Installation of Sprinkler Systems*,<sup>7</sup> because 18.3.5.4 references 9.7.1.1(1); yet, for hotels and dormitories, 28.3.5.3 recognizes sprinkler systems installed per NFPA 13R, *Standard for the Installation of Sprinkler Systems in Low-Rise Residential Occupancies*,<sup>8</sup> if the hotel or dormitory is not more than four stories in height; otherwise the sprinkler system must meet the requirements of NFPA 13.

### 10.1.3 Definitions.

**10.1.3.1 General.** For definitions see Chapter 3 Definitions.

**10.1.3.2 Special Definitions.** A list of special terms used in this chapter follows:

(1) **Contents and Furnishings.** See 3.3.49.

The term *contents and furnishings* is defined in 3.3.49 as “any movable objects in a building that normally are secured or otherwise put in place for functional reasons, excluding (1) parts of the internal structure of the building, and (2) any items meeting the definition of interior finish.” Application of the definition of *interior finish* in 3.3.92.2 and the provisions of 10.2.1.5 will result in some items commonly considered by building occupants as contents or furnishings being classified and treated under the stricter provisions applicable to interior finish.

(2) **Flashover.** See 3.3.114.

The term *flashover* is defined in 3.3.114 as “a stage in the development of a contained fire in which all exposed surfaces reach ignition temperature more or less simultaneously and fire spreads rapidly throughout the space.” The space in which flashover occurs is not tenable for human occupancy, and tenability is not ensured in adjacent spaces not adequately separated from the fire compartment. The provisions of Section 10.2, and the associated interior finish limitations imposed by the occupancy chapters, are directed at preventing a fire involving the interior finish materials alone from resulting in flashover.

(3) **Interior Finish.** See 3.3.92.2.

The term *interior finish* is defined in 3.3.92.2 as “the exposed surfaces of walls, ceilings, and floors within buildings.”

The faster a fire develops, the greater the threat it represents to the occupants of a building, and the more difficult it will be to control. Wall and ceiling surfaces of a building can have a major influence on how fast a fire develops. In establishing restrictions for the use of interior finish materials, the Code’s intent is to limit the rate at which fire spreads across the interior surfaces of a building.

Any large fire within a building represents a threat to occupants. A successful fire protection strategy attempts to limit the size of a fire. Any interior finish that acts as a “fuse” to spread flame and involve objects remote from the point of origin, or that contributes fuel to the early growth of a fire and causes a large fire, is undesirable. The restrictions found in the Code for wall and ceiling finishes vary, depending on the occupancy classification. Where occupants are immobile or where security measures restrict freedom of movement (as in health care facilities or detention and correctional facilities), conservative interior finish limits are set. In contrast, more relaxed limits are permitted in industrial or storage occupancies where occupants are assumed to be alert and mobile.

Interior finishes are the interior surfaces of a building that are generally secured in place. Thus, wall, ceiling, and column coverings are considered interior wall and ceiling finishes. The surfaces of movable walls or folding partitions are also to be treated as interior finishes (see 10.2.1.5). However, the Code permits the authority having jurisdiction (AHJ) to exercise judgment in determining the criteria that constitute interior finish. For example, a loosely hanging tapestry placed against a wall would not normally be considered interior finish. However, a large tapestry that is secured to and covers a major portion of a wall could promote the rapid growth of fire and might be judged as constituting interior finish.

Furnishings (including high-backed, plastic-upholstered restaurant booths) are not normally considered as interior finish, even in cases where the furnishings are fixed in place. However, some furnishings are considered interior finish, as detailed in 10.2.1.5. See the definition of *contents and furnishings* in 3.3.49 and in the commentary following 10.1.3.2(1).

**(4) Interior Ceiling Finish.** See 3.3.92.1.

The term *interior ceiling finish* is defined in 3.3.92.1 as “the interior finish of ceilings.” Flame spread typically occurs from burning furnishings located at floor level, moving upward vertically along wall surfaces to the ceiling, and spreading across the ceiling surface. Where ceiling materials are not controlled as interior finish, the spread of fire across the ceiling surface might outpace that of the building occupants moving toward exits.

**(5) Interior Floor Finish.** See 3.3.92.3.

The term *interior floor finish* is defined in 3.3.92.3 as “the interior finish of floors, ramps, stair treads and risers, and other walking surfaces.” Interior floor finish includes both exposed surfaces of structural floor systems and decorative floor treatments, such as wood flooring, carpet, or other resilient flooring materials. Coverings on stair risers and treads are regulated as interior floor finish, even though stair risers are oriented vertically. This definition recognizes that the fire performance of floor coverings on stair risers and treads is similar to that of other floor surfaces.

**(6) Interior Wall Finish.** See 3.3.92.4.

The term *interior wall finish* is defined in 3.3.92.4 as “the interior finish of columns, fixed or movable walls, and fixed or movable partitions.” Wall surfaces can serve as a medium for spreading flame from burning furnishings, located at floor level, upward vertically to the ceiling. The likelihood of flashover can be reduced if flames can be stopped from reaching the ceiling.

Many of the provisions of Section 10.2 are focused at slowing the rate of flame spread across wall surfaces.

---

## 10.2\* Interior Finish

**A.10.2** The requirements pertaining to interior finish are intended to restrict the spread of fire over the continuous surface forming the interior portions of a building.

Table A.10.2 shows the fire test methods and classification criteria that apply to different interior finish materials.

**Table A.10.2 Fire Testing of Interior Finish Materials**

Material	Test Method	Acceptance Criterion	Application Requirement	Section
Interior wall and ceiling finish materials, except as shown in this table	ASTM E 84 or ANSI/UL 723	Class A, in accordance with 10.2.3.4(1)	As required by relevant sections	10.2.3
	ASTM E 84 or ANSI/UL 723	Class B, in accordance with 10.2.3.4(2)	As required by relevant sections	10.2.3
	ASTM E 84 or ANSI/UL 723	Class C, in accordance with 10.2.3.4(3)	As required by relevant sections	10.2.3
	NFPA 286	In accordance with 10.2.3.7.2	Permitted where Class A, B, or C is required by relevant sections	10.2.3.2
Materials having thicknesses < 1/8 in. (<0.90 mm) applied directly to a noncombustible or limited-combustible surface of walls or ceilings	No testing required			10.2.1.2
Exposed portions of structural members complying with requirements for buildings of Type IV (2HH) construction in accordance with NFPA 220	No testing required			10.2.3.1

(continues)

Table A.10.2 Continued

Material	Test Method	Acceptance Criterion	Application Requirement	Section
Cellular or foamed plastics (exposed foamed plastics and foamed plastics used in conjunction with textile or vinyl facing or cover)	NFPA 286	In accordance with 10.2.3.7.2	Permitted where Class A, B, or C is required by relevant sections	10.2.4.3.1.1(1)
	ANSI/UL 1715	Pass	Permitted where Class A, B, or C is required by relevant sections	10.2.4.3.1.1(2)
	ANSI/UL 1040	Pass	Permitted where Class A, B, or C is required by relevant sections	10.2.4.3.1.1(3)
	FM 4880	Pass	Permitted where Class A, B, or C is required by relevant sections	10.2.4.3.1.1(4)
	Suitable large-scale fire test that substantiates combustibility characteristics for use intended under actual fire conditions	Pass	Permitted where Class A, B, or C is required by relevant sections	10.2.4.3.1
Textile wall coverings	NFPA 286	In accordance with 10.2.3.7.2	Permitted where Class A, B, or C is required by relevant sections	10.2.4.1(6)
	NFPA 265, Method B	In accordance with 10.2.3.7.1	Permitted on walls and partitions	10.2.4.1(5)
	ASTM E 84 or ANSI/UL 723	Class A, in accordance with 10.2.3.4(1)	Permitted on walls, but also requires sprinklers per Section 9.7	10.2.4.1(1)
	ASTM E 84 or ANSI/UL 723	Class A, in accordance with 10.2.3.4(1)	Permitted on partitions not exceeding three-quarters of the floor-to-ceiling height or not exceeding 8 ft (2440 mm) in height, whichever is less	10.2.4.1(2)
	ASTM E 84 or ANSI/UL 723	Class A, in accordance with 10.2.3.4(1)	Permitted to extend not more than 48 in. (1220 mm) above finished floor on ceiling-height walls and ceiling-height partitions	10.2.4.1(3)
	ASTM E 84 or ANSI/UL 723	Class A, in accordance with 10.2.3.4(1)	Previously approved existing installations of textile material meeting the requirements of Class A permitted to be continued to be used	10.2.4.1(4)
Expanded vinyl wall coverings	NFPA 286	In accordance with 10.2.3.7.2	Permitted where Class A, B, or C is required by relevant sections	10.2.4.2(6)
	NFPA 265, Method B	In accordance with 10.2.3.7.1	Permitted on walls and partitions	10.2.4.2(5)
	ASTM E 84 or ANSI/UL 723	Class A, in accordance with 10.2.3.4(1)	Permitted on walls, but also requires sprinklers per Section 9.7	10.2.4.2(1)

Table A.10.2 Continued

Material	Test Method	Acceptance Criterion	Application Requirement	Section
	ASTM E 84 or ANSI/UL 723	Class A, in accordance with 10.2.3.4(1)	Permitted on partitions not exceeding three-quarters of the floor-to-ceiling height or not exceeding 8 ft (2440 mm) in height, whichever is less	10.2.4.2(2)
	ASTM E 84 or ANSI/UL 723	Class A, in accordance with 10.2.3.4 (1)	Permitted to extend not more than 48 in. (1220 mm) above finished floor on ceiling-height walls and ceiling-height partitions	10.2.4.2(3)
	ASTM E 84 or ANSI/UL 723	Class A, B, or C, in accordance with 10.2.3.4	Existing installations of materials with appropriate wall finish classification for occupancy involved, and with classification in accordance with the provisions of 10.2.3.4	10.2.4.2(4)
Textile ceiling coverings	NFPA 286	In accordance with 10.2.3.7.2	Permitted where Class A, B, or C is required by relevant sections	10.2.4.1(6)
	ASTM E 84 or ANSI/UL 723	Class A, in accordance with 10.2.3.4(1)	Permitted on walls, but also requires sprinklers per Section 9.7	10.2.4.1(1)
	ASTM E 84 or ANSI/UL 723	Class A, in accordance with 10.2.3.4(1)	Previously approved existing installations of textile material meeting the requirements of Class A permitted to be continued to be used	10.2.4.1(4)
Expanded vinyl ceiling coverings	NFPA 286	In accordance with 10.2.3.7.2	Permitted where Class A, B, or C is required by relevant sections	10.2.4.2(6)
	ASTM E 84 or ANSI/UL 723	Class A, in accordance with 10.2.3.4(1)	Permitted on walls, but also requires sprinklers per Section 9.7	10.2.4.2(1)
	ASTM E 84 or ANSI/UL 723	Class A, B, or C, in accordance with 10.2.3.4	Existing installations of materials with appropriate wall finish classification for occupancy involved, and with classification in accordance with the provisions of 10.2.3.4	10.2.4.2(4)

Material	Test Method	Acceptance Criterion	Application Requirement	Section
Floor coverings, other than carpet, judged to represent an unusual hazard (excluding traditional finish floors and floor coverings, such as wood flooring and resilient floor coverings)	NFPA 253	Critical radiant flux $\geq 0.1 \text{ W/cm}^2$	All areas	10.2.7.2
Interior floor finish, other than carpet and carpetlike materials	NFPA 253	Class I: Critical radiant flux $\geq 0.45 \text{ W/cm}^2$ , in accordance with 10.2.7.4	As required by relevant sections	10.2.7.3
	NFPA 253	Class II: Critical radiant flux $\geq 0.22 \text{ W/cm}^2$ , in accordance with 10.2.7.4	As required by relevant sections	10.2.7.3
Wall base [interior floor trim material used at junction of wall and floor to provide a functional or decorative border, and not exceeding 6 in. (150 mm) in height]	NFPA 253	Class II: Critical radiant flux $\geq 0.22 \text{ W/cm}^2$ , in accordance with 10.2.7.4	All areas	10.2.5.2
	NFPA 253	Class I: Critical radiant flux $\geq 0.45 \text{ W/cm}^2$ , in accordance with 10.2.7.4	If interior floor finish is required to meet Class I critical radiant flux	10.2.5.2
Floor finish of traditional type, such as wood flooring and resilient floor coverings	No testing required			10.2.2.2

### 10.2.1\* General.

**A.10.2.1** The requirements pertaining to interior finish are intended to restrict the spread of fire over the continuous surface forming the interior portions of a building. The presence of multiple paint layers has the potential for paint delamination and bubbling or blistering of paint. Testing (NFPA *Fire Technology*, August 1974, “Fire Tests of Building Interior Covering Systems,” David Waksman and John Ferguson, Institute for Applied Technology, National Bureau of Standards) has shown that adding up to two layers of paint with a dry film thickness of about 0.007 in. (0.18 mm) will not change the fire properties of surface-covering systems. Testing has shown that the fire properties of the surface-covering systems are highly substrate dependent and that thin coatings generally take on the characteristics of the substrate. When exposed to fire, the delamination, bubbling, and blistering of paint can result in an accelerated rate of flame spread.

**10.2.1.1** Classification of interior finish materials shall be in accordance with tests made under conditions simulating actual

installations, provided that the authority having jurisdiction is permitted to establish the classification of any material for which classification by a standard test is not available, unless otherwise provided in 10.2.1.2 or 10.2.1.4.

Paragraph 10.2.1.1 presents two concepts.

First, for interior finish materials to be classified properly based on performance under a standardized test, such test needs to be indicative of the conditions under which the material will actually be installed. For example, thin wood paneling applied directly to wall framing studs can be expected to spread flame differently than thin wood paneling applied to gypsum wallboard. This concept is explained, in part, in A.10.2.1. See also the commentary following A.10.2.3.4.

Second, the authority having jurisdiction is responsible for classifying interior finish materials for which standardized test data is not available. The AHJ is free to use whatever tools are available (such as experience, intuition, comparative field testing) and will generally take the conservative approach of banning the use of suspect materials for which there is no supporting

data. The regulation of interior finish materials is an important part of the total package of life safety offered by compliance with the *Code*.

**10.2.1.2** The provisions of **10.2.1.1** shall not apply to materials having a total thickness of less than  $\frac{1}{8}$  in. (0.9 mm) that are applied directly to the surface of walls and ceilings where both of the following conditions are met:

- (1) The wall or ceiling surface is a noncombustible or limited-combustible material.
- (2) The materials applied meet the requirements of Class A interior wall or ceiling finish when tested in accordance with **10.2.3**, using fiber cement board as the substrate material.

**Paragraph 10.2.1.2** addresses the issue of thin coverings, which was covered in earlier editions of the *Code* by a simply worded, performance-based criterion that was difficult to use and enforce. The *Code* recognized that thin coverings [those less than  $\frac{1}{8}$  in. (0.9 mm) in thickness] with surface-burning characteristics not greater than that of paper would not significantly affect the fire performance of the basic wall or ceiling material. If assurance were provided that such a thin covering had surface-burning characteristics not greater than those of paper, the thin material would not be subject to regulation as an interior finish. Therefore, the material's flame spread rating wasn't needed, which, in turn, meant that no fire testing was required. The problem was that, without running fire tests, it was impossible to determine whether a thin material had surface-burning characteristics that were greater than those of paper.

The wording of **10.2.1.2** does not exempt newly installed thin materials from testing, but it does exempt thin materials from testing with the actual substrate or backing material that will be used in the final installed state, provided that the material is installed on a noncombustible or limited-combustible surface (e.g., gypsum wallboard). If there were no exemption, thin materials, such as paint (whose liquid suspension state dries to become a thin layer of material) and wallpaper, would be required to be fire tested in combination with numerous backing materials. A complete set of test results, representative of the many forms of substrates in common use, would be prohibitively expensive to collect. **Paragraph 10.2.1.2** permits the material to be tested only with fiber cement board as the substrate material. If the material, when tested in that configuration, meets the requirements for Class A interior finish (see **10.2.3.4.1**), no further regulation by **Section 10.2** is required.

Thermally thin coverings, such as paint and wallpaper coverings, when secured to a noncombustible substrate such as fiber cement board, will not significantly alter the performance of the substrate during a fire. However, thicker coverings, such as multiple layers of wallpaper, can and have contributed to rapid fire growth. For example, multiple layers of wall coverings contributed to rapid fire growth in the multiple-death fire in the Holiday Inn in Cambridge, Ohio, which occurred on July 31, 1979.<sup>9</sup>

The provision of **10.2.1.2** has the effect of requiring any wall or ceiling covering (or multiple layers of such covering) of more than  $\frac{1}{8}$  in. (0.9 mm) in thickness to undergo the full test series required of other interior finish materials so as to be representative of actual installations. Painted surfaces might be evaluated using the steps that follow:

1. Determine the classification of the interior finish material (e.g., wood wainscoting) in its unpainted configuration, and verify that it complies with the applicable limits (e.g., **38.3.3**, if the occupancy is new business, and **7.1.4** for exit enclosures).
2. Obtain a paint product for which the manufacturer has documented that it achieves a Class A rating when applied to a substrate of cement fiber board and tested in accordance with ASTM E 84, *Standard Test Method for Surface Burning Characteristics of Building Materials*,<sup>10</sup> or ANSI/UL 723, *Standard for Test for Surface Burning Characteristics of Building Materials*.<sup>11</sup>
3. Apply the paint to the substrate described in step 1 above such that the thickness is less than  $\frac{1}{8}$  in. (0.9 mm).
4. Where the above steps 1 through 3 are followed, the paint is exempt from being tested on the substrate on which it is actually installed.

Where the thickness of an interior finish material is  $\frac{1}{8}$  in. (0.9 mm) or greater, it must be tested as it will actually be installed. For example, the performance of thermally thin coverings is altered by the nature of the substrate over which they are installed.<sup>12</sup> Adhesives might also be an important factor in performance. In the case of composites (such as textile wall coverings over gypsum board), the adhesive should be sufficient to maintain a bond between the "finish" and the substrate. However, excess adhesive might contribute to a fire. Tests of textile wall coverings have shown that changing adhesives, or simply changing the application rate for the same adhesive, might significantly alter product performance.<sup>13</sup> Tests to qualify assemblies should use adhesives and application rates similar to actual installations.

Similarly, a product that undergoes testing in intimate contact with a mineral board should be installed in contact with a mineral board or similar substrate. Also, where products are tested in intimate contact with a substrate, results might be altered if the product is installed with air space behind the covering.

**10.2.1.3** If a material having a total thickness of less than  $\frac{1}{8}$  in. (0.9 mm) is applied to a surface that is not noncombustible or not limited-combustible, the provisions of **10.2.1.1** shall apply.

**10.2.1.4** Approved existing installations of materials applied directly to the surface of walls and ceilings in a total thickness of less than  $\frac{1}{8}$  in. (0.9 mm) shall be permitted to remain in use, and the provisions of **10.2.2** through **10.2.3.7.2** shall not apply.

The provision of 10.2.1.4 exempts existing interior wall and ceiling finish materials having a thickness of less than  $\frac{1}{28}$  in. (0.9 mm) from the testing requirements of 10.2.2, provided that they are acceptable to the authority having jurisdiction. See the definition of *approved existing* in 3.3.81.1. The intent of the exemption is to permit existing finishes, such as a single layer of paint or wallpaper, to remain in place without documentation of its flame spread characteristics, since determination of its classification might be impractical. It is expected that such finish materials have a finite service life, and, upon replacement, tested products can be applied or installed. Where the AHJ determines that the finish material is of such character that regulation is necessary, use of the exemption provided by 10.2.1.4 can be denied.

**10.2.1.5\*** Fixed or movable walls and partitions, paneling, wall pads, and crash pads applied structurally or for decoration, acoustical correction, surface insulation, or other purposes shall be considered interior finish and shall not be considered decorations or furnishings.

**A.10.2.1.5** Such partitions are intended to include washroom water closet partitions.

Prior to the 2006 edition of the *Code*, there was significant confusion among users on how to address materials placed on walls after construction and occupancy of the building. Often when materials were brought into an occupied building and attached to the walls, the authority having jurisdiction was petitioned to

treat such materials as decorations or furnishings. If the AHJ agreed to classifying such materials as decorations or furnishings, then the materials might go unregulated or, at best, would be tested per NFPA 701, *Standard Methods of Fire Tests for Flame Propagation of Textiles and Films*<sup>14</sup> (see 10.3.1), which is not the appropriate test for interior finish materials. The criteria in 10.2.1.5 provide the needed clarification.

Pads are often attached to walls in school gymnasiums to cushion the impact if a student collides with the wall. Such pads applied to, or placed against, walls need to be treated as interior wall finish. Similar pads placed on the floor should be considered as contents and furnishings.

**10.2.1.6** Lockers constructed of combustible materials shall be considered interior finish.

Historically, lockers in occupancies such as schools have been constructed of metal and have not posed a significant fire hazard. More recently, however, lockers constructed of wood and plastic have been made available. Because it is typical for lockers to line the walls of corridors, where they are constructed of combustible materials, they need to be regulated as interior wall finish materials in accordance with 10.2.1.6.

### 10.2.2\* Use of Interior Finishes.

**A.10.2.2** Table A.10.2.2 provides a compilation of the interior finish requirements of 7.1.4 and the occupancy chapters (Chapters 12 through 42) of this *Code*.

**Table A.10.2.2 Interior Finish Classification Limitations**

Occupancy	Exits	Exit Access Corridors	Other Spaces
Assembly — New			
>300 occupant load	A I or II	A or B I or II	A or B NA
≤300 occupant load	A I or II	A or B I or II	A, B, or C NA

	I or II		NA
Business and Ambulatory Health Care — Existing	A or B	A or B	A, B, or C
Industrial	A or B	A, B, or C	A, B, or C
	I or II	I or II	NA
Storage	A or B	A, B, or C	A, B, or C
	I or II		NA

NA: Not applicable. Notes:

- (1) Class A interior wall and ceiling finish — flame spread index, 0–25 (new applications); smoke developed index, 0–450.
- (2) Class B interior wall and ceiling finish — flame spread index, 26–75 (new applications); smoke developed index, 0–450.
- (3) Class C interior wall and ceiling finish — flame spread index, 76–200 (new applications); smoke developed index, 0–450.
- (4) Class I interior floor finish — critical radiant flux, not less than 0.45 W/cm<sup>2</sup>.
- (5) Class II interior floor finish — critical radiant flux, not more than 0.22 W/cm<sup>2</sup>, but less than 0.45 W/cm<sup>2</sup>.
- (6) Automatic sprinklers — where a complete standard system of automatic sprinklers is installed, interior wall and ceiling finish with a flame spread rating not exceeding Class C is permitted to be used in any location where Class B is required, and Class B interior wall and ceiling finish is permitted to be used in any location where Class A is required; similarly, Class II interior floor finish is permitted to be used in any location where Class I is required, and no interior floor finish classification is required where Class II is required. These provisions do not apply to new detention and correctional occupancies.
- (7) Exposed portions of structural members complying with the requirements for heavy timber construction are permitted.

<sup>†</sup>See corresponding chapters for details.

Traditional floor coverings, such as wood flooring and resilient tile, do not contribute to the early growth of fire. Paragraph 10.2.2.2 has the effect of exempting traditional floor coverings from the restrictions that would otherwise be applicable. However, the authority having jurisdiction can require substantiation of the performance of any unfamiliar floor covering. For example, imitation wood floors made of plastic, artificial turf, artificial surfaces of athletic fields, and certain types of carpeting are products that might merit substantiation. If the AHJ judges that a floor covering warrants testing and substantiation, or if an occupancy chapter imposes restrictions, then the floor covering must be treated as interior floor finish. It would, therefore, be regulated on the basis of tests conducted in accordance with the flooring radiant panel test required in 10.2.7.

**10.2.2.1** Requirements for interior wall and ceiling finish shall apply as follows:

- (1) Where specified elsewhere in this *Code* for specific occupancies (see *Chapter 7* and *Chapters 11 through 43*)
- (2) As specified in 10.2.3 through 10.2.6.

**10.2.2.2\*** Interior floor finish shall comply with 10.2.7 under any of the following conditions:

- (1) Where floor finish requirements are specified elsewhere in the *Code*
- (2) Where the fire performance of the floor finish cannot be demonstrated to be equivalent to floor finishes with a critical radiant flux of at least 0.1 W/cm<sup>2</sup>

**A.10.2.2.2** This paragraph recognizes that traditional finish floors and floor coverings, such as wood flooring and resilient floor coverings, have not proved to present an unusual hazard.

**10.2.3\* Interior Wall or Ceiling Finish Testing and Classification.** Interior wall or ceiling finish that is required elsewhere in this *Code* to be Class A, Class B, or Class C shall be classified based on test results from ASTM E 84, *Standard Test Method for Surface Burning Characteristics of Building Materials*, or ANSI/UL 723, *Standard for Test for Surface Burning Characteristics of Building Materials*, except as indicated in 10.2.3.1 or 10.2.3.2.

**A.10.2.3** ASTM E 84, *Standard Test Method of Surface Burning Characteristics of Building Materials*, and UL 723, *Standard for Test for Surface Burning Characteristics of Building Materials*, are considered nationally recognized consensus standard test methods for determining the flame spread index and smoke developed index of building materials and are likely to yield equivalent test results. (See also A.10.2.4.1.)

Flame spread and smoke development characteristics are both quantified and recorded in the results of a test conducted in accordance with ASTM E 84, *Standard Test Method for Surface Burning Characteristics of Building Materials*, or ANSI/UL 723, *Standard for Test for Surface Burning Characteristics of Building*

*Materials*. The test is also commonly referred to as the “Steiner tunnel test” (named after its inventor, Al Steiner, who developed the test at Underwriters Laboratories in 1944) and, generically, as the “tunnel test.”

**10.2.3.1** Exposed portions of structural members complying with the requirements for Type IV(2HH) construction in accordance with NFPA 220, *Standard on Types of Building Construction*, or with the building code shall be exempt from testing and classification in accordance with ASTM E 84, *Standard Test Method for Surface Burning Characteristics of Building Materials*, or ANSI/UL 723, *Standard for Test for Surface Burning Characteristics of Building Materials*.

Type IV(2HH) construction has traditionally been called “heavy timber construction.” Exposed surfaces of the structural members, such as wood columns, beams, and girders, meet the definition of interior wall and ceiling finish. All heavy timber structural members are required to be of substantial thickness, as detailed in NFPA 220, *Standard on Types of Building Construction*,<sup>15</sup> and NFPA 5000®, *Building Construction and Safety Code*.<sup>16</sup> Thus, none are thermally thin, so they do not present the concerns addressed in the commentary that follows 10.2.1.2.

Paragraph 10.2.3.1 recognizes that exposed surfaces of heavy timber structural members can be safely used where Class A, Class B, or Class C interior wall and ceiling finish is required. Such wood members often have flame spread ratings in the range of 76 to 200 and, therefore, are typically classified as Class C interior finish. The exemption is based on the fact that the structural members are located at intervals and do not constitute a continuous surface that allows flame to spread, for example, across a ceiling.

**10.2.3.2** Interior wall and ceiling finish tested in accordance with NFPA 286, *Standard Methods of Fire Tests for Evaluating Contribution of Wall and Ceiling Interior Finish to Room Fire Growth*, and meeting the conditions of 10.2.3.7.2 shall be permitted to be used where interior wall and ceiling finish is required to be Class A in accordance with ASTM E 84, *Standard Test Method for Surface Burning Characteristics of Building Materials*, or ANSI/UL 723, *Standard for Test for Surface Burning Characteristics of Building Materials*.

Paragraph 10.2.3.2 permits materials that meet the criteria specified in 10.2.3.7.2, where tested in accordance with NFPA 286, *Standard Methods of Fire Tests for Evaluating Contribution of Wall and Ceiling Interior Finish to Room Fire Growth*,<sup>17</sup> to be used as both interior wall finish and interior ceiling finish, even where other *Code* provisions require interior wall and ceiling finish to be Class A in accordance with 10.2.3.4.1. Testing per NFPA 286, combined with performance criteria specified by 10.2.3.7.2, represents an improvement over testing in accordance with ASTM E 84, *Standard Test Method for Surface Burning Characteristics of Building Materials*, or ANSI/UL 723, *Standard for Test for Surface Burning Characteristics of Building Materials*, and classification

in accordance with 10.2.3.4. ASTM E 84 and ANSI/UL 723 test a sample that is mounted in a horizontal orientation to cover the 18 in. (455 mm) wide by 24 ft (7.3 m) long ceiling of the test tunnel. NFPA 286 tests a sample that fully covers three walls of the 8 ft (2440 mm) wide by 12 ft (3660 mm) long by 8 ft (2440 mm) high test chamber — and the ceiling as well if the results are to be applied to interior ceiling finish. See the commentary following 10.2.3.7.2.

Note that 10.2.3.2 does not require testing per NFPA 286; rather, it offers this test procedure as an alternative to that of meeting the Class A classification criteria of 10.2.3.4.1, based on results from the more traditional ASTM E 84 or ANSI/UL 723 test protocol.

**10.2.3.3** For fire-retardant coatings, see 10.2.6.

**10.2.3.4\*** Products required to be tested in accordance with ASTM E 84, *Standard Test Method for Surface Burning Characteristics of Building Materials*, or ANSI/UL 723, *Standard for Test for Surface Burning Characteristics of Building Materials*, shall be grouped in the classes described in 10.2.3.4.1 through 10.2.3.4.3 in accordance with their flame spread index and smoke developed index, except as indicated in 10.2.3.4.4.

**A.10.2.3.4** It has been shown that the method of mounting interior finish materials usually affects actual performance. The use of standard mounting methods will be helpful in determining appropriate fire test results. Where materials are tested in intimate contact with a substrate to determine a classification, such materials should be installed in intimate contact with a similar substrate. Such details are especially important for “thermally thin” materials. For further information, see ASTM E 84, *Standard Test Method for Surface Burning Characteristics of Building Materials*.

Some interior wall and ceiling finish materials, such as fabrics not applied to a solid backing, do not lend themselves to a test made in accordance with ASTM E 84. In such cases, the large-scale test outlined in NFPA 701, *Standard Methods of Fire Tests for Flame Propagation of Textiles and Films*, is permitted to be used. In 1989 the NFPA Technical Committee on Fire Tests eliminated the so-called “small-scale test” from NFPA 701 because the results had been shown not to represent a fire performance that corresponded to what happened in real scale. Since then, NFPA 701 no longer contains a “small-scale test” but it now contains two tests (Test 1 and Test 2), which apply to materials as a function of their areal density. Thus NFPA 701 Test 1 applies to fabrics (other than vinyl-coated fabric blackout linings) having an areal density less than or equal to 21 oz/yd<sup>2</sup> (700 g/m<sup>2</sup>), while NFPA 701 Test 2 applies to fabrics with an areal density greater than 21 oz/yd<sup>2</sup> (700 g/m<sup>2</sup>), vinyl-coated fabric blackout linings, decorative objects, and films. Representations that materials or products have been tested to the small-scale test in NFPA 701 normally refer to the pre-1989 small-scale test, which no longer exists and which does not represent acceptable fire performance.

Prior to 1978, the test report described by ASTM E 84 included an evaluation of the fuel contribution as well as the flame spread index and the smoke developed index. However, it is now recognized that the measurement on which the fuel contribution is based does not provide a valid measure. Therefore, although the data are recorded during the test, the information is no longer normally reported. Classification of interior wall and ceiling finish thus relies only on the flame spread index and smoke developed index.

The 450 smoke developed index limit is based solely on obscurity. (See A.10.2.4.1.)

**10.2.3.4.1 Class A Interior Wall and Ceiling Finish.** Class A interior wall and ceiling finishes shall be those finishes with a flame spread index of 0–25 and a smoke developed index of 0–450 and shall include any material classified at 25 or less on the flame spread index test scale and 450 or less on the smoke developed index test scale.

**10.2.3.4.2 Class B Interior Wall and Ceiling Finish.** Class B interior wall and ceiling finishes shall be those finishes with a flame spread index of 26–75 and a smoke developed index of 0–450 and shall include any material classified at more than 25 but not more than 75 on the flame spread index test scale and 450 or less on the smoke developed index test scale.

**10.2.3.4.3 Class C Interior Wall and Ceiling Finish.** Class C interior wall and ceiling finishes shall be those finishes with a flame spread index of 76–200 and a smoke developed index of 0–450 and shall include any material classified at more than 75 but not more than 200 on the flame spread index test scale and 450 or less on the smoke developed index test scale.

**10.2.3.4.4** Existing interior finish shall be exempt from the smoke developed index criteria of 10.2.3.4.1 through 10.2.3.4.3.

Samples are tested in accordance with ASTM E 84, *Standard Test Method for Surface Burning Characteristics of Building Materials*, or ANSI/UL 723, *Standard for Test for Surface Burning Characteristics of Building Materials*, as mandated by 10.2.3.4, using a noncombustible, fiber cement board backing. Specimens are tested with adhesives and joints and under other conditions that simulate the actual installation of a product in a building. These fire test standards provide a general indication of product performance only if the product is installed in a fashion similar to that which has been tested. Available data demonstrate that the performance of interior finish materials varies, depending on mounting conditions.<sup>18</sup> For example, a product installed over a combustible substrate tends to propagate fire more readily than would be typical of the same product installed over a noncombustible substrate.

Further, a wall covering installed with air space behind the covering tends to spread flame more readily than one installed in contact with a noncombustible substrate. Therefore, mounting techniques must be carefully considered in the evaluation of probable product performance.

Exhibit 10.2

ASTM E 84 room tunnel test apparatus. (Photo courtesy of Herbert Blenstein)

Exhibit 10.2 illustrates the ASTM E 84 room tunnel test apparatus. The same apparatus is required for testing per ANSI/UL 723.

Interior wall and ceiling finish classifications in accordance with 10.2.3.4 are based mainly on flame spread indices, with an additional requirement that the smoke developed index not exceed a common value of 450, regardless of the class into which the material falls based on flame spread. Flame spread classifications offer a general indication of the speed with which fire might spread across the surface of a material. In assessing the hazard posed by a material on the basis of flame spread, it is assumed that a person might be close to the fire and would be directly exposed to the energy associated with the actual flames. By contrast, the purpose of the smoke developed index is to address visual obscuration of the egress path by smoke. Thus, an interior wall and ceiling finish material with a low smoke developed index should provide better visibility in a given egress route than a material with a relatively high smoke developed index. Given that the smoke developed index is a cumulative measurement over the prescribed test duration, it is based on both quantity and rate of smoke liberation.

The Code requires the use of specific classes of interior wall and ceiling finish materials, which are differentiated by their allowable flame spread index, based on consideration of their installed location within the building, the building's egress paths, and the occupancy in question. Different classes of interior finish materials are specified for an office area, for example, as opposed to an exit stair enclosure or exit access corridor. The different classes recognize that, when escaping a building, people must move away from the flames while traveling through the means of egress toward an exit. The classes of interior finishes that are considered acceptable within an open office, therefore, are different from those that are required for exit enclosures. Similarly, occupancies used by those who have decreased capabilities of self-preservation have stricter interior finish requirements than occupancies used by fully ambulatory

occupants. For example, although both hospitals and hotels provide sleeping accommodations, interior finish requirements for hospitals are more stringent, because hospital patients are less capable of self-preservation.

The same smoke developed index limit is used for all three flame spread classifications. This limit recognizes that smoke generated during a fire might affect visibility both in the vicinity of, and remote from, the fire. Large buildings can be quickly filled with smoke as a result of a fire. An upper limit has been established, therefore, that applies to new interior finish materials, regardless of their location.

Per 10.2.3.4.4, existing wall and ceiling finish materials are exempted from the smoke development limitation. In existing buildings, existing interior finish materials are restricted only on the basis of flame spread. Prior to the 1976 edition, the Code did not regulate interior finish materials based on smoke development. As a general rule, the replacement of existing materials only because they were previously approved exclusively on the basis of flame spread is not warranted.

The smoke developed index limit of 450 was determined on the basis of research conducted by Underwriters Laboratories Inc. A 5000 ft<sup>3</sup> (140 m<sup>3</sup>) room equipped with illuminated exit signs was filled with smoke from the tunnel test chamber. The time required to reach various stages of exit sign obscuration was recorded and compared to the smoke developed indices for the different materials involved. The report states that "materials having smoke developed ratings above 325 showed 'good' to 'marginal' visibility — scale readings of 3 to 4.8 — in a few cases; other materials produced conditions of 'marginal' to obscuration in the six-minute period."<sup>19</sup>

Considering both time and smoke levels, the limit of 450 on smoke development as used in the Code has been judged to be reasonable. There is no direct relationship between flame spread and smoke development. For example, in the report referenced in the previous paragraph, one material had a flame spread index of 490 and a smoke developed index of 57, while another had a flame spread index of 44 and a smoke developed index of 1387.

The smoke development limit of 450 is based solely on the level of visual obscuration. Although not addressed by the requirements for interior finishes, other important factors used in evaluating materials on the basis of smoke generation are the effects of irritability and toxicity caused by gases. Smoke might also act as an irritant, further reducing visibility, and might, in addition, have a debilitating physiological effect on people attempting to escape from a building. Such effects are not evaluated by the current smoke development limit. Previous editions of the Code permitted the authority having jurisdiction to regulate products presenting an "unreasonable life hazard due to the character of the products of decomposition." This provision was deleted in the 1988 edition of the Code due to its unenforceable nature. The adverse physiological effects on the human body caused by exposure to heat and the effects of inhaling hot gases should also be considered as part of an

overall hazard risk assessment and should be considered separately from the interior finish requirements of Section 10.2.

**10.2.3.5** The classification of interior finish specified in 10.2.3.4 shall be that of the basic material used by itself or in combination with other materials.

**10.2.3.6** Wherever the use of Class C interior wall and ceiling finish is required, Class A or Class B shall be permitted. Where Class B interior wall and ceiling finish is required, Class A shall be permitted.

Paragraph 10.2.3.6 recognizes that the Code sets minimum criteria. An interior finish material that performs better than that specifically prescribed by the Code is always permitted.

**10.2.3.7\*** Products tested in accordance with NFPA 265, *Standard Methods of Fire Tests for Evaluating Room Fire Growth Contribution of Textile or Expanded Vinyl Wall Coverings on Full Height Panels and Walls*, shall comply with the criteria of 10.2.3.7.1. Products tested in accordance with NFPA 286, *Standard Methods of Fire Tests for Evaluating Contribution of Wall and Ceiling Interior Finish to Room Fire Growth*, shall comply with the criteria of 10.2.3.7.2.

**A.10.2.3.7** The methodology specified in NFPA 265, *Standard Methods of Fire Tests for Evaluating Room Fire Growth Contribution of Textile or Expanded Vinyl Wall Coverings on Full Height Panels and Walls*, includes provisions for measuring smoke obscuration. Such measurement is considered desirable, but the basis for specific recommended values is not currently available. (See A.10.2.4.1.)

**10.2.3.7.1\*** The interior finish shall comply with all of the following when tested using method B of the test protocol of NFPA 265, *Standard Methods of Fire Tests for Evaluating Room Fire Growth Contribution of Textile or Expanded Vinyl Wall Coverings on Full Height Panels and Walls*:

- (1) During the 40 kW exposure, flames shall not spread to the ceiling.
- (2) The flame shall not spread to the outer extremities of the samples on the 8 ft × 12 ft (2440 mm × 3660 mm) walls.
- (3) Flashover, as described in NFPA 265, shall not occur.
- (4) For new installations, the total smoke released throughout the test shall not exceed 1000 m<sup>2</sup>.

**A.10.2.3.7.1** See A.10.2.3.7 and A.10.2.4.1.

The Code recognizes the use of Method B of NFPA 265, *Standard Methods of Fire Tests for Evaluating Room Fire Growth Contribution of Textile or Expanded Vinyl Wall Coverings on Full Height Panels and Walls*,<sup>20</sup> but not Method A. Method B is the more rigorous test and requires that the test specimens be mounted to cover fully both 8 ft × 12 ft (2440 mm × 3660 mm) walls and the 8 ft × 8 ft (2440 mm × 2440 mm) rear wall. Method A is a screening test for which the test specimen is mounted as 24 in. (610 mm) wide

**Exhibit 10.3**

Test compartment required by NFPA 265.

strips at the intersection of two adjacent walls and along the top of those two walls where they meet the ceiling.

The NFPA 265 test compartment is depicted in Exhibit 10.3.

**10.2.3.7.2** The interior finish shall comply with all of the following when tested using the test protocol of NFPA 286, *Standard Methods of Fire Tests for Evaluating Contribution of Wall and Ceiling Interior Finish to Room Fire Growth*:

- (1) During the 40 kW exposure, flames shall not spread to the ceiling.
- (2) The flame shall not spread to the outer extremity of the sample on any wall or ceiling.
- (3) Flashover, as described in NFPA 286, shall not occur.
- (4) The peak heat release rate throughout the test shall not exceed 800 kW.
- (5) For new installations, the total smoke released throughout the test shall not exceed 1000 m<sup>2</sup>.

NFPA 286, *Standard Methods of Fire Tests for Evaluating Contribution of Wall and Ceiling Interior Finish to Room Fire Growth*, was developed specifically to measure the following:

1. Extent of flame spread and burning relative to the realistically sized and mounted sample
2. Whether flashover occurs
3. Peak rate of heat release
4. Total smoke released throughout the test

The peak heat release rate of 800 kW, as specified by 10.2.3.7.2(4), was new to the 2006 edition of the Code. It was added because 10.2.3.2 permits materials that meet the criteria specified in 10.2.3.7.2, where tested in accordance with NFPA 286,

to be used as both interior wall finish and interior ceiling finish, even where other *Code* provisions require interior wall and ceiling finish to be Class A in accordance with 10.2.3.4.1. Some interior finish materials can be produced less expensively, so as to be somewhat less fire safe if they need to meet only the criteria of 10.2.3.7.2 (based on testing per NFPA 286) without a peak heat release rate criterion, instead of having to pass the flame spread criteria for Class A required by 10.2.3.4.1 (based on testing per ASTM E 84, *Standard Test Method for Surface Burning Characteristics of Building Materials*, or ANSI/UL 723, *Standard for Test for Surface Burning Characteristics of Building Materials*). The peak heat release rate criterion associated with testing per NFPA 286 helps equalize the anomaly in the test methods.

Materials that meet the criteria for Class A interior finish when tested per ASTM E 84 or ANSI/UL 723, and that do not flashover the test room when tested per NFPA 286, typically have a peak heat release rate of less than 400 kW. The 800 kW peak heat release rate criterion of 10.2.3.7.2(4) was chosen to help ensure that materials that have already been tested are not unnecessarily penalized.

The test room used for NFPA 286 testing is the same size as that used for NFPA 265, *Standard Methods of Fire Tests for Evaluating Room Fire Growth Contribution of Textile or Expanded Vinyl Wall Coverings on Full Height Panels and Walls*, testing and is shown in Exhibit 10.3. If the test results are to be applied only to interior wall finish, then the test specimens are mounted to cover fully both 8 ft × 12 ft (2440 mm × 3660 mm) walls and the 8 ft × 8 ft (2440 mm × 2440 mm) rear wall. If the test results are to be applied both to interior wall finish and interior ceiling finish, then, in addition, the test specimen is mounted to cover the ceiling. If the test results are to be applied only to interior ceiling finish, then the test specimen is mounted to cover the ceiling only.

#### 10.2.4\* Specific Materials.

**A.10.2.4** Surface nonmetallic raceway products, as permitted by NFPA 70, *National Electrical Code*, are not interior finishes and are not subject to the provisions of Chapter 10.

**10.2.4.1\* Textile Wall and Textile Ceiling Materials.** The use of textile materials on walls or ceilings shall comply with one of the following conditions:

- (1) Textile materials meeting the requirements of Class A when tested in accordance with ASTM E 84, *Standard Test Method for Surface Burning Characteristics of Building Materials*, or ANSI/UL 723, *Standard for Test for Surface Burning Characteristics of Building Materials*, using the specimen preparation and mounting method of ASTM E 2404, *Standard Practice for Specimen Preparation and Mounting of Textile, Paper or Polymeric (Including Vinyl) Wall or Ceiling Coverings, and of Facings and Wood Veneers Intended to be Applied on Site Over a Wood Substrate, to Assess Surface Burning Characteristics* (see 10.2.3.4), shall be permitted on the walls or ceilings of rooms or areas protected by an approved automatic sprinkler system.
- (2) Textile materials meeting the requirements of Class A when tested in accordance with ASTM E 84 or ANSI/UL 723, using the specimen preparation and mounting method of ASTM E 2404 (see 10.2.3.4), shall be permitted on partitions that do not exceed three-quarters of the floor-to-ceiling height or do not exceed 8 ft (2440 mm) in height, whichever is less.
- (3) Textile materials meeting the requirements of Class A when tested in accordance with ASTM E 84 or ANSI/UL 723, using the specimen preparation and mounting method of ASTM E 2404 (see 10.2.3.4), shall be permitted to extend not more than 48 in. (1220 mm) above the finished floor on ceiling-height walls and ceiling-height partitions.
- (4) Previously approved existing installations of textile material meeting the requirements of Class A when tested in accordance with ASTM E 84 or ANSI/UL 723 (see 10.2.3.4) shall be permitted to be continued to be used.
- (5) Textile materials shall be permitted on walls and partitions where tested in accordance with NFPA 265, *Standard Methods of Fire Tests for Evaluating Room Fire Growth Contribution of Textile or Expanded Vinyl Wall Coverings on Full Height Panels and Walls*. (See 10.2.3.7.)
- (6) Textile materials shall be permitted on walls, partitions, and ceilings where tested in accordance with NFPA 286, *Standard Methods of Fire Tests for Evaluating Contribution of Wall and Ceiling Interior Finish to Room Fire Growth*. (See 10.2.3.7.)

Textile materials are permitted to be used as interior wall or ceiling finish only where such materials meet any one of the provisions of 10.2.4.1(1) through (6).

Prior to the 1988 edition of the *Code*, the danger of carpet-like textile coverings used on walls and ceilings was recognized and regulated by a requirement that only Class A tufted or napped materials be used, even in a sprinklered building. In 1981, eight people died at the nonsprinklered Las Vegas Hilton Hotel when a fire began in an elevator lobby and was fueled by carpetlike textile wall and ceiling finishes that did not meet the qualifications for Class A interior finish.<sup>21</sup> Other than the textile wall and ceiling finish materials, sheer sunscreen material at the window, and a cushioned seat pad on a metal bench, little combustible material was present to fuel the fire in the elevator lobby, an example of which is depicted in Exhibit 10.4. Yet, the elevator lobby went to flashover, the fire broke out the windows and extended to a nearly identical elevator lobby on the floor above, and the events repeated themselves in a leapfrog fashion, burning out the elevator lobbies from the eighth floor through the twenty-fourth floor. See Exhibit 10.5.

Research sponsored by the American Textile Manufacturers Institute (ATMI) and conducted by the Fire Research Laboratory of the University of California at Berkeley between March 1985

**Exhibit 10.4**

Las Vegas Hilton elevator lobby with carpetlike textile wall and ceiling finish material.

**Exhibit 10.5**

Resulting fire spread involving elevator lobbies on eighth through twenty-fourth floors.

and January 1986 was described in the report "Room Fire Experiments of Textile Wall Coverings."<sup>22</sup> This research demonstrated that consideration of only the flame spread index, as measured by ASTM E 84, *Standard Test Method for Surface Burning Characteristics of Building Materials*, or ANSI/UL 723, *Standard for Test for Surface Burning Characteristics of Building Materials*, might not reliably predict the fire behavior of textile wall and ceiling coverings. Test results indicate that not all Class A textile wall coverings are alike with respect to their potential for producing room flashover; some are capable of producing room flashover when subjected to an ignition source scenario that models a small fuel item (such as a wastebasket) igniting a chair or similar furnishing, while others are not. Simply requiring textile wall coverings to be classified as Class A does not ensure the level of life safety intended by the *Code*.

The testing at the University of California was conducted in an 8 ft × 12 ft × 8 ft high (2440 mm × 3660 mm × 2440 mm high) room using a gas diffusion burner as an ignition source. Products undergoing evaluation — various textile wall coverings — were applied to the walls; the gas diffusion burner and ignition source were placed in the corner of the room. Two of the 16 products tested — one a tufted wall covering, the other a woven wall covering — were known to have flame spread ratings of 25 or less when tested in accordance with ASTM E 84 or ANSI/UL 723. When tested using the room-corner procedure, these two products readily spread flame and caused the fire in the test room to grow quickly to a large size, causing full room involvement — that is, flashover. Concerns about the performance of these low flame spread textile wall coverings led to the requirement of 10.2.4.1(5) for full-scale room-corner testing to qualify products for use in nonsprinklered buildings.

The tests revealed that the method of mounting, including adhesive and application rate, can be critically important to product fire performance. Changing the application rate of the same adhesive or changing the adhesive can cause a product that is assumed to be safe to exhibit unsatisfactory performance.

Caution should be exercised where combinations of textile wall and ceiling coverings are installed. Experience has shown that combinations of textile wall and ceiling coverings might result in intense burning. The University of California testing included only wall coverings; research conducted at the Illinois Institute of Technology Research Institute indicates that flame spread is more likely to occur with combinations of combustible wall and ceiling coverings than in those situations involving only combustible wall coverings or only combustible ceiling coverings.<sup>23</sup> Therefore, full-scale room-corner testing, using an appropriately sized ignition source, is necessary to substantiate the performance of textile wall and ceiling coverings.

NFPA 265, *Standard Methods of Fire Tests for Evaluating Room Fire Growth Contribution of Textile or Expanded Vinyl Wall Coverings on Full Height Panels and Walls*, serves as a nationally recognized room-corner fire test to be used specifically for textile wall coverings. Its use is addressed in 10.2.3.7, 10.2.3.7.1, and 10.2.4.1(5).

Paragraph 10.2.4.1(6) expands the options for specialized fire tests representative of an actual installation by recognizing the use of NFPA 286, *Standard Methods of Fire Tests for Evaluating Contribution of Wall and Ceiling Interior Finish to Room Fire Growth*. See the commentary that follows 10.2.3.7.2(5).

Paragraphs 10.2.4.1(1) through (4) address other conditions under which textile wall coverings are permitted to be used.

**A.10.2.4.1** Previous editions of the *Code* have regulated textile materials on walls and ceilings using ASTM E 84, *Standard Test Method for Surface Burning Characteristics of Building Materials*, or ANSI/UL 723, *Standard for Test for Surface Burning Characteristics of Building Materials*. Full-scale room/corner fire test research has shown that flame spread indices produced by ASTM E 84 or ANSI/UL 723 might not reliably predict all aspects of the fire behavior of textile wall and ceiling coverings.

NFPA 265, *Standard Methods of Fire Tests for Evaluating Room Fire Growth Contribution of Textile or Expanded Vinyl Wall Coverings on Full Height Panels and Walls*, and NFPA 286, *Standard Methods of Fire Tests for Evaluating Contribution of Wall and Ceiling Interior Finish to Room Fire Growth*, both known as room/corner tests, were developed for assessing the fire and smoke obscuration performance of textile wall coverings and interior wall and ceiling finish materials, respectively. As long as an interior wall or ceiling finish material is tested by NFPA 265 or NFPA 286, as appropriate, using a mounting system, substrate, and adhesive (if appropriate) that are representative of actual use, the room/corner test provides an adequate evaluation of a product's flammability and smoke obscuration behavior. Manufacturers, installers, and specifiers should be encouraged to use NFPA 265 or NFPA 286, as appropriate — but not both — because each of these standard fire tests has the ability to characterize actual product behavior, as opposed to data generated by tests using ASTM E 84 or ANSI/UL 723, which only allow comparisons of one product's performance with another. If a manufacturer or installer chooses to test a wall finish in accordance with NFPA 286, additional testing in accordance with ASTM E 84 or ANSI/UL 723 is not necessary.

The test results from ASTM E 84 or ANSI/UL 723 are suitable for classification purposes but should not be used as input into fire models, because they are not generated in units suitable for engineering calculations. Actual test results for heat, smoke, and combustion product release from NFPA 265, and from NFPA 286, are suitable for use as input into fire models for performance-based design.

**10.2.4.2\* Expanded Vinyl Wall and Expanded Vinyl Ceiling Materials.** The use of expanded vinyl wall or expanded vinyl ceiling materials shall comply with one of the following conditions:

- (1) Materials meeting the requirements of Class A when tested in accordance with ASTM E 84, *Standard Test Method for Surface Burning Characteristics of Building Materials*, or ANSI/UL 723, *Standard for Test for Surface Burning Characteristics of Building Materials*, using the specimen preparation and mounting method of ASTM E 2404, *Standard Practice for Specimen Preparation and Mounting of Textile, Paper, or Polymeric (Including Vinyl) Wall or Ceiling Coverings, and of Facings and Wood Veneers Intended to be Applied on Site Over a Wood Substrate, to Assess Surface Burning Characteristics* (see 10.2.3.4), shall be permitted on the walls or ceilings of rooms or areas protected by an approved automatic sprinkler system.
  - (2) Materials meeting the requirements of Class A when tested in accordance with ASTM E 84 or ANSI/UL 723, using the specimen preparation and mounting method of ASTM E 2404 (see 10.2.3.4), shall be permitted on partitions that do not exceed three-quarters of the floor-to-ceiling height or do not exceed 8 ft (2440 mm) in height, whichever is less.
  - (3) Materials meeting the requirements of Class A when tested in accordance with ASTM E 84 or ANSI/UL 723, using the specimen preparation and mounting method of ASTM E 2404 (see 10.2.3.4), shall be permitted to extend not more than 48 in. (1220 mm) above the finished floor on ceiling-height walls and ceiling-height partitions.
  - (4) Previously approved existing installations of materials meeting the requirements for the occupancy involved, when tested in accordance with ASTM E 84 or ANSI/UL 723 (see 10.2.3.4), shall be permitted to be continued to be used.
  - (5) Materials shall be permitted on walls and partitions where tested in accordance with NFPA 265, *Standard Methods of Fire Tests for Evaluating Room Fire Growth Contribution of Textile or Expanded Vinyl Wall Coverings on Full Height Panels and Walls*. (See 10.2.3.7.)
  - (6) Materials shall be permitted on walls, partitions, and ceilings where tested in accordance with NFPA 286, *Standard Methods of Fire Tests for Evaluating Contribution of Wall and Ceiling Interior Finish to Room Fire Growth*. (See 10.2.3.7.)
- A.10.2.4.2** Expanded vinyl wall covering consists of a woven textile backing, an expanded vinyl base coat layer, and a nonexpanded vinyl skin coat. The expanded base coat layer is a homogeneous vinyl layer that contains a blowing agent. During processing, the blowing agent decomposes, which causes this layer to expand by forming closed cells. The total thickness of the wall covering is approximately 0.055 in. to 0.070 in. (1.4 mm to 1.8 mm).
- The provisions of 10.2.4.2, which address expanded vinyl wall coverings and expanded vinyl ceiling coverings (described in A.10.2.4.2), are similar to those of 10.2.4.1, which are applicable to textile wall coverings. It is the intent of the Code to require compliance with 10.2.4.2 wherever expanded vinyl wall or ceiling finish materials are installed, regardless of occupancy classification.
- 10.2.4.3 Cellular or Foamed Plastic.** Cellular or foamed plastic materials shall not be used as interior wall and ceiling finish unless specifically permitted by 10.2.4.3.1 or 10.2.4.3.2. The requirements of 10.2.4.3 through 10.2.4.3.2 shall apply both to exposed foamed plastics and to foamed plastics used in conjunction with a textile or vinyl facing or cover.
- 10.2.4.3.1\*** Cellular or foamed plastic materials shall be permitted where subjected to large-scale fire tests that substantiate their combustibility and smoke release characteristics for the use intended under actual fire conditions.
- A.10.2.4.3.1** See A.10.2.4.3.1.2.
- 10.2.4.3.1.1** One of the following fire tests shall be used for assessing the combustibility of cellular or foamed plastic materials as interior finish:
- (1) NFPA 286, *Standard Methods of Fire Tests for Evaluating Contribution of Wall and Ceiling Interior Finish to Room Fire Growth*, with the acceptance criteria of 10.2.3.7.2

- (2) ANSI/UL 1715, *Standard for Fire Test of Interior Finish Material* (including smoke measurements, with total smoke release not to exceed 1000 m<sup>2</sup>)
- (3) ANSI/UL 1040, *Standard for Fire Test of Insulated Wall Construction*
- (4) ANSI/FM 4880, *American National Standard for Evaluating Insulated Wall or Wall and Roof/Ceiling Assemblies, Plastic Interior Finish Materials, Plastic Exterior Building Panels, Wall/Ceiling Coating Systems, Interior or Exterior Finish Systems*

**10.2.4.3.1.2\*** The tests shall be performed on a finished foamed plastic assembly related to the actual end-use configuration, including any cover or facing, and at the maximum thickness intended for use.

**A.10.2.4.3.1.2** Both NFPA 286, *Standard Methods of Fire Tests for Evaluating Contribution of Wall and Ceiling Interior Finish to Room Fire Growth*, and ANSI/UL 1715, *Standard for Fire Test of Interior Finish Material*, contain smoke obscuration criteria. ANSI/UL 1040, *Standard for Fire Test of Insulated Wall Construction*, and FM 4880, *Approval Standard for Class I Insulated Wall or Wall and Roof/Ceiling Panels; Plastic Interior Finish Materials; Plastic Exterior Building Panels; Wall/Ceiling Coating Systems; Interior or Exterior Finish Systems*, do not. Smoke obscuration is an important component of the fire performance of cellular or foamed plastic materials.

**10.2.4.3.2** Cellular or foamed plastic shall be permitted for trim not in excess of 10 percent of the specific wall or ceiling area to which it is applied, provided that it is not less than 20 lb/ft<sup>3</sup> (320 kg/m<sup>3</sup>) in density, is limited to ½ in. (13 mm) in thickness and 4 in. (100 mm) in width, and complies with the requirements for Class A or Class B interior wall and ceiling finish as described in 10.2.3.4; however, the smoke developed index shall not be limited.

The prohibition of 10.2.4.3 on the use of foamed plastics within buildings is based on actual fire experience in which foamed plastics have contributed to very rapid fire development.<sup>24</sup> It also acknowledges that tunnel testing per ASTM E 84, *Standard Test Method for Surface Burning Characteristics of Building Materials*, or ANSI/UL 723, *Standard for Test for Surface Burning Characteristics of Building Materials* (see 10.2.3.4), might not accurately assess the potential hazard of plastics in general. Therefore, if cellular or foamed plastics are to be used within a building, their use needs to be substantiated on the basis of large-scale fire tests that simulate conditions of actual use. Four such tests are offered in 10.2.4.3.1.1(1) through (4).

Note that the provisions of 10.2.4.3 through 10.2.4.3.2 apply not only to exposed foamed plastics but also to foamed plastics used as backings for textile or vinyl facings or cover materials. An assembly comprised of foamed plastic backings in conjunction with a textile or vinyl facing or cover is expected to behave differently under fire tests than if just the textile or vinyl facing were tested alone.

Paragraph 10.2.4.3.2 permits the limited use of cellular or foamed plastics as a substitute for traditional wood trim, assuming their performance under fire exposure will be comparable to that of wood. To control the mass of the material that can be used, limits have been established on width and thickness. The intent in establishing a minimum density of 20 lb/ft<sup>3</sup> (320 kg/m<sup>3</sup>) is to prohibit the use of lightweight [1 lb/ft<sup>3</sup> to 3 lb/ft<sup>3</sup> (16 kg/m<sup>3</sup> to 48 kg/m<sup>3</sup>)], readily available, foamed plastics as trim.

Limiting plastic trim to Class A or Class B materials, in combination with the 10 percent area limit for walls and ceilings, imposes a greater restriction than that which applies to wood. This limitation ensures that the performance of the plastic trim will be equivalent or superior to that of more traditional materials.

In establishing the 10 percent limit, it is intended that the trim will be used around doors and windows or at the junction of walls and ceilings. Therefore, the trim will be somewhat uniformly distributed throughout the room. There would be a significant difference in the probable performance of wall and ceiling finish if the 10 percent limit were concentrated in one area.

**10.2.4.4\* Light-Transmitting Plastics.** Light-transmitting plastics shall be permitted to be used as interior wall and ceiling finish if approved by the authority having jurisdiction.

**A.10.2.4.4** Light-transmitting plastics are used for a variety of purposes, including light diffusers, exterior wall panels, skylights, canopies, glazing, and the like. Previous editions of the *Code* have not addressed the use of light-transmitting plastics. Light-transmitting plastics will not normally be used in applications representative of interior finishes. Accordingly, ASTM E 84, *Standard Test Method for Surface Burning Characteristics of Building Materials*, or ANSI/UL 723, *Standard for Test for Surface Burning Characteristics of Building Materials*, can produce test results that might or might not apply.

Light-transmitting plastics are regulated by model building codes such as NFPA 5000, *Building Construction and Safety Code*. Model building codes provide adequate regulation for most applications of light-transmitting plastics. Where an authority having jurisdiction determines that a use is contemplated that differs from uses regulated by model building codes, light-transmitting plastics in such applications can be substantiated by fire tests that demonstrate the combustibility characteristics of the light-transmitting plastics for the use intended under actual fire conditions.

For additional information on light transmitting plastics, see Section 48.7 of NFPA 5000.

Building code provisions typically regulate light-transmitting plastics. Paragraph 10.2.4.4 gives the authority having jurisdiction the ability to regulate light-transmitting plastics; A.10.2.4.4 offers guidance for such regulation. See Chapter 48 of NFPA 5000, *Building Construction and Safety Code*, which addresses plastics, for additional guidance.

**10.2.4.5 Decorations and Furnishings.** Decorations and furnishings that do not meet the definition of interior finish, as defined in 3.3.92.2, shall be regulated by the provisions of Section 10.3.

**10.2.4.6 Metal Ceiling and Wall Panels.** Listed factory finished metal ceiling and wall panels meeting the requirements of Class A when tested in accordance with ASTM E 84, *Standard Test Method for Surface Burning Characteristics of Building Materials*, or ANSI/UL 723, *Standard for Test for Surface Burning Characteristics of Building Materials* (see 10.2.3.4), shall be permitted to be finished with one additional application of paint. Such painted panels shall be permitted for use in areas where Class A interior finishes are required. The total paint thickness shall not exceed  $\frac{1}{28}$  in. (0.9 mm).

Metal-based ceiling and wall panels are used extensively in custom-designed acoustical ceiling and wall systems. Often the customer desires a special custom color to meet aesthetic requirements. Although the manufacturer can certify the performance of the factory finish, it is not possible to test and certify all the custom colors that are requested. These finishes are applied post-production, using a process where thickness of paint application is controlled. The  $\frac{1}{28}$  in. (0.9 mm) thickness criterion used in 10.2.4.6 is taken from 10.2.1.2 as a safe thickness for which the exemption does not sacrifice safety.

**10.2.4.7 Polypropylene (PP) and High-Density Polyethylene (HDPE).** Polypropylene and high-density polyethylene materials shall not be permitted as interior wall or ceiling finish unless the material complies with the requirements of 10.2.3.7.2. The tests shall be performed on a finished assembly and on the maximum thickness intended for use.

Polypropylene (PP) and high-density polyethylene (HDPE) are thermoplastic materials that, when exposed to fire, have a tendency to melt and form pool fires that can potentially burn vigorously. The requirement of 10.2.4.7 specifies that products, such as toilet room privacy dividers constructed of PP or HDPE, are considered interior finish materials and must comply with the performance criteria of 10.2.3.7.2 when tested in accordance with NFPA 286, *Standard Methods of Fire Tests for Evaluating Contribution of Wall and Ceiling Interior Finish to Room Fire Growth*. Testing such materials for their flame spread and smoke development characteristics using the tunnel test of ASTM E 84, *Standard Test Method for Surface Burning Characteristics of Building Materials*, or ANSI/UL 723, *Standard for Test for Surface Burning Characteristics of Building Materials*, does not sufficiently characterize their fire performance. The NFPA 286 room-corner test provides a more realistic determination of their contribution to fire development in a room.

**10.2.4.8 Site-Fabricated Stretch Systems.** For new installations, site-fabricated stretch systems containing all three components described in the definition in Chapter 3 shall be tested in the manner intended for use and shall comply with the

requirements of 10.2.3 or 10.2.3.2. If the materials are tested in accordance with ASTM E 84, *Standard Test Method for Surface Burning Characteristics of Building Materials*, or ANSI/UL 723, *Standard for Test for Surface Burning Characteristics of Building Materials*, specimen preparation and mounting shall be in accordance with ASTM E 2573, *Standard Practice for Specimen Preparation and Mounting of Site-Fabricated Stretch Systems to Assess Surface Burning Characteristics*.

Site-fabricated stretch systems are comprised of three components as described in the definition in 3.3.274.2:

1. A frame (constructed of plastic, wood, metal, or other material) used to hold fabric in place
2. A core material (infill, with the correct properties for the application)
3. An outside layer, comprised of a textile, fabric, or vinyl, that is stretched taut and held in place by tension or mechanical fasteners via the frame

Although many authorities having jurisdiction might have previously regulated site-fabricated stretch systems, such as the fabric wall depicted in Exhibit 10.6, as interior finish, the requirements of 10.2.4.8 make it clear that such systems are, in fact, interior finish, and must be tested accordingly. Additionally, where such systems are tested using the Steiner tunnel test in accordance with ASTM E 84, *Standard Test Method for Surface Burning Characteristics of Building Materials*, or ANSI/UL 723, *Standard for Test for Surface Burning Characteristics of Building Materials*, they must be mounted in the tunnel using the procedure specified by ASTM E 2573, *Standard Practice for Specimen Preparation and Mounting of Site-Fabricated Stretch Systems to Assess Surface Burning Characteristics*.<sup>25</sup>

**10.2.4.9 Reflective Insulation Materials.** Reflective insulation materials shall be tested in the manner intended for use and shall comply with the requirements of 10.2.3. If the materials are tested

**Exhibit 10.6**

Example of a site-fabricated stretch system. (Photo courtesy of Novawall® Systems, Inc.)

in accordance with ASTM E 84, *Standard Test Method for Surface Burning Characteristics of Building Materials*, or ANSI/UL 723, *Standard for Test for Surface Burning Characteristics of Building Materials*, specimen preparation and mounting shall be in accordance with ASTM E 2599, *Standard Practice for Specimen Preparation and Mounting of Reflective Insulation, Radiant Barrier, and Vinyl Stretch Ceiling Materials for Building Applications to Assess Surface Burning Characteristics*.

### 10.2.5 Trim and Incidental Finish.

**10.2.5.1 General.** Interior wall and ceiling trim and incidental finish, other than wall base in accordance with 10.2.5.2 and bulletin boards, posters, and paper in accordance with 10.2.5.3, not in excess of 10 percent of the specific wall and ceiling areas of any room or space to which it is applied shall be permitted to be Class C materials in occupancies where interior wall and ceiling finish of Class A or Class B is required.

**10.2.5.2 Wall Base.** Interior floor trim material used at the junction of the wall and the floor to provide a functional or decorative border, and not exceeding 6 in. (150 mm) in height, shall meet the requirements for interior wall finish for its location or the requirements for Class II interior floor finish as described in 10.2.7.4 using the test described in 10.2.7.3. If a Class I floor finish is required, the interior floor trim shall be Class I.

#### 10.2.5.3 Bulletin Boards, Posters, and Paper.

**10.2.5.3.1** Bulletin boards, posters, and paper attached directly to the wall shall not exceed 20 percent of the aggregate wall area to which they are applied.

**10.2.5.3.2** The provision of 10.2.5.3.1 shall not apply to artwork and teaching materials in sprinklered educational or day-care occupancies in accordance with 14.7.4.3(2), 15.7.4.3(2), 16.7.4.3(2), or 17.7.4.3(2).

Subsection 10.2.5 is intended to permit the use of wood trim around doors and windows as a decoration or as functional molding (such as for chair rails). Wood trim must meet the criteria for Class C materials. See 10.2.4.3.2 for restrictions applicable to plastic trim. Where such trim is used in rooms or spaces requiring the use of Class A or Class B materials, the trim is permitted to constitute not more than 10 percent of the aggregate wall or ceiling area to ensure that the trim will be more or less uniformly distributed throughout the room or space. If the trim is concentrated in a single, sizable, continuous pattern (e.g., on one wall of a room), the materials could contribute to rapid fire growth.

The wall base provisions of 10.2.5.2 regulate the common practice of running flooring up onto the lowest portion of a wall where it meets the floor. The 6 in. (150 mm) maximum height criterion recognizes the limitations of judging an interior wall finish material based on a test method developed to evaluate flame spread for interior floor finish materials exposed to a flaming radiant heat source. Note that, even where the interior floor finish of a room or space is not required to be Class I or Class II in accordance

with 10.2.7.4, the flooring material wrapped up onto the wall is required to be tested and classified per 10.2.7.3 and 10.2.7.4.

The educational and day-care occupancy chapters have regulated artwork and teaching materials that are attached directly to walls for many editions of the *Code* — see 14.7.4.3, 15.7.4.3, 16.7.4.3, and 17.7.4.3. The provisions of 10.2.5.3 codify the subject for all other occupancies. Bulletin boards, posters, and paper attached directly to a wall serve as de facto interior finish materials with the potential for spreading flame. The 20 percent maximum aggregate wall area criterion of 10.2.5.3.1 helps ensure that there are not sufficient expanses of such materials, for which classification per 10.2.3.4 is unfeasible and unenforceable, that could spread flame more quickly than would occur with wall finish materials complying with applicable interior finish requirements based on testing per ASTM E 84, *Standard Test Method for Surface Burning Characteristics of Building Materials*, or ANSI/UL 723, *Standard for Test for Surface Burning Characteristics of Building Materials*.

### 10.2.6\* Fire-Retardant Coatings.

**A.10.2.6** Fire-retardant coatings need to be applied to surfaces properly prepared for the material, and application needs to be consistent with the product listing. Deterioration of coatings applied to interior finishes can occur due to repeated cleaning of the surface or painting over applied coatings.

**10.2.6.1\*** The required flame spread index or smoke developed index of existing surfaces of walls, partitions, columns, and ceilings shall be permitted to be secured by applying approved fire-retardant coatings to surfaces having higher flame spread index values than permitted. Such treatments shall be tested, or shall be listed and labeled for application to the material to which they are applied, and shall comply with the requirements of NFPA 703, *Standard for Fire Retardant-Treated Wood and Fire-Retardant Coatings for Building Materials*.

**A.10.2.6.1** It is the intent of the *Code* to mandate interior wall and ceiling finish materials that obtain their fire performance and smoke developed characteristics in their original form. However, in renovations, particularly those involving historic buildings, and in changes of occupancy, the required fire performance or smoke developed characteristics of existing surfaces of walls, partitions, columns, and ceilings might have to be secured by applying approved fire-retardant coatings to surfaces having higher flame spread ratings than permitted. Such treatments should comply with the requirements of NFPA 703, *Standard for Fire Retardant-Treated Wood and Fire-Retardant Coatings for Building Materials*. When fire-retardant coatings are used, they need to be applied to surfaces properly prepared for the material, and application needs to be consistent with the product listing. Deterioration of coatings applied to interior finishes can occur due to repeated cleaning of the surface or painting over applied coatings, but permanency must be assured in some appropriate fashion. Fire-retardant coatings must possess the desired

degree of permanency and be maintained so as to retain the effectiveness of the treatment under the service conditions encountered in actual use.

**10.2.6.2\*** Surfaces of walls, partitions, columns, and ceilings shall be permitted to be finished with factory-applied fire-retardant-coated products that have been listed and labeled to demonstrate compliance with the requirements of ASTM E 2768, *Standard Test Method for Extended Duration Surface Burning Characteristics of Building Materials*, on the coated surface.

**A.10.2.6.2** The intent of this section is that factory-applied fire-retardant-coated products, such as panels or tiles applied to walls or ceilings, replace the existing finish and are not applied on top of the existing finish.

**10.2.6.3** Fire-retardant coatings or factory-applied fire-retardant coated assemblies shall possess the desired degree of permanency and shall be maintained so as to retain the effectiveness of the treatment under the service conditions encountered in actual use.

Fire-retardant paints, coatings, and penetrants are sometimes used to improve the flame spread ratings of materials or assemblies used as interior finishes within buildings. Fire-retardant treatments are permitted to be used to satisfy the flame spread requirements only for existing interior finish materials within existing buildings.

Fire retardants are generally surface treatments that — through intumescence or other chemical reaction — will delay the ignition and slow the flame spread of a material. The nature of the material to which the treatment has been applied is not changed. Fire exposures of sufficient duration or intensity can ultimately cause a treated material to burn. Therefore, as a rule, materials with favorable intrinsic performance characteristics are preferred over those that achieve a satisfactory level of performance through the use of externally applied treatments. However, external treatments, where properly applied and maintained, can be effective in achieving reasonable fire performance.

Note that 10.2.6.1 permits fire-retardant coatings to be either tested or listed, as the product might have been tested with adequate results but not yet listed when being considered for application. Additionally, such products must comply with NFPA 703, *Standard for Fire Retardant-Treated Wood and Fire-Retardant Coatings for Building Materials*,<sup>26</sup> which contains criteria related to testing.

Fire-retardant paints, coatings, and penetrants must be applied in strict accordance with the manufacturer's instructions. Most fire-retardant coatings require an application rate that is three-to-four times greater than that of ordinary paints. Application is usually done by brush, spray, immersion, or pressure treatment. The treatment should be reapplied or renewed at regular intervals. Treatments that might be removed by regular maintenance, washing, or cleaning procedures will require periodic examination and reapplication to maintain the required level of performance.

The use of fire retardants can improve the performance of some materials from Class C to Class B; similarly, Class B materials can, in some cases, be upgraded to Class A. Likewise, materials having flame spread ratings in excess of 200 can sometimes be upgraded to Class C.

In approving fire-retardant treatments, the authority having jurisdiction should take into consideration that, in reducing flame spread, some fire-retardant treatments increase a material's capacity for smoke generation.

The provision of 10.2.6.2 is intended to permit assemblies with factory-applied coatings, provided that they are listed and labeled by an approved testing laboratory to indicate compliance with the noted test standard.

### 10.2.7\* Interior Floor Finish Testing and Classification.

**A.10.2.7** The flooring radiant panel provides a measure of a floor covering's tendency to spread flames where located in a corridor and exposed to the flame and hot gases from a room fire. The flooring radiant panel test method is to be used as a basis for estimating the fire performance of a floor covering installed in the building corridor. Floor coverings in open building spaces and in rooms within buildings merit no further regulation, provided that it can be shown that the floor covering is at least as resistant to spread of flame as a material that meets the U.S. federal flammability standard 16 CFR 1630, "Standard for the Surface Flammability of Carpets and Rugs" (FF 1-70). All carpeting sold in the United States since 1971 is required to meet this standard and, therefore, is not likely to become involved in a fire until a room reaches or approaches flashover. Therefore, no further regulations are necessary for carpet, other than carpet in exitways and corridors.

It has not been found necessary or practical to regulate interior floor finishes on the basis of smoke development.

Full-scale fire tests and fire experience have shown that floor coverings in open building spaces merit no regulation beyond the U.S. federally mandated DOC FF 1-70 "pill test." This is because floor coverings meeting the pill test will not spread flame significantly until a room fire approaches flashover. At flashover, the spread of flame across a floor covering will have minimal impact on the already existing hazard. The minimum critical radiant flux of a floor covering that will pass the FF 1-70 test has been determined to be approximately 0.04 W/cm<sup>2</sup> (Tu, King-Mon and Davis, Sanford, "Flame Spread of Carpet Systems Involved in Room Fires," NFSIR 76-1013, Center for Fire Research, National Bureau of Standards, June 1976). The flooring radiant panel is only able to determine critical radiant flux values to 0.1 W/cm<sup>2</sup>. This provision will prevent use of a non-complying material, which can create a problem, especially when the *Code* is used outside the United States where U.S. federal regulation FF 1-70 (16 CFR 1630) is not mandated.

**10.2.7.1\*** Carpet and carpetlike interior floor finishes shall comply with ASTM D 2859, *Standard Test Method for Ignition Characteristics of Finished Textile Floor Covering Materials*.

**A.10.2.7.1** Compliance with 16 CFR 1630, “Standard for the Surface Flammability of Carpets and Rugs” (FFI-70), is considered equivalent to compliance with ASTM D 2859, *Standard Test Method for Ignition Characteristic of Finished Textile Floor Covering Materials*.

**10.2.7.2\*** Floor coverings, other than carpet for which 10.2.2.2 establishes requirements for fire performance, shall have a minimum critical radiant flux of 0.1 W/cm<sup>2</sup>.

**A.10.2.7.2** The fire performance of some floor finishes has been tested, and traditional finish floors and floor coverings, such as wood flooring and resilient floor coverings, have not proved to present an unusual hazard.

**10.2.7.3\*** Interior floor finishes shall be classified in accordance with 10.2.7.4, based on test results from NFPA 253, *Standard Method of Test for Critical Radiant Flux of Floor Covering Systems Using a Radiant Heat Energy Source*, or ASTM E 648, *Standard Test Method for Critical Radiant Flux of Floor Covering Systems Using a Radiant Heat Energy Source*.

**A.10.2.7.3** ASTM E 648, *Standard Test Method for Critical Radiant Flux of Floor Covering Systems Using a Radiant Heat Energy Source*, and NFPA 253, *Standard Method of Test for Critical Radiant Flux of Floor Covering Systems Using a Radiant Heat Energy Source*, are considered nationally recognized consensus standard test methods for determining the critical radiant flux from floor covering systems and are likely to yield equivalent test results.

Experience and full-scale fire test data have shown that floor coverings of modest resistance to flame spread are unlikely to become involved in the early growth of a fire. The testing of flooring materials in accordance with 10.2.7.1 and 10.2.7.2 is relatively easy to accomplish. The testing helps to identify floor finish materials that have a modest resistance to flame spread.

Where floor coverings are regulated by the occupancy chapters, the evaluation is based on tests conducted in accordance with NFPA 253, *Standard Method of Test for Critical Radiant Flux of Floor Covering Systems Using a Radiant Heat Energy Source*,<sup>27</sup> or ASTM E 648, *Standard Test Method for Critical Radiant Flux of Floor Covering Systems Using a Radiant Heat Energy Source*.<sup>28</sup> The flooring radiant panel test was specifically developed to evaluate the tendency of a floor covering to propagate flame.

Fire tests conducted by the National Bureau of Standards (now the National Institute of Standards and Technology) demonstrate that carpet that passes the federal flammability standard 16 CFR 1630, “Standard for the Surface Flammability of Carpets and Rugs”<sup>29</sup> (also known as FF 1-70 or the “pill test”), is not likely to become involved in a fire until a room reaches or approaches flashover.<sup>30</sup> Since all carpet manufactured for sale in the United States has been required since April 1971 to meet the pill test, no further regulation is necessary for carpet located within rooms.

On the other hand, it has been shown that floor coverings might propagate flame under the influence of a sizable exposure fire. For example, it has been shown that carpet located in a corridor might spread flame when subjected to the energy emanating from the doorway of a room fully developed in fire. The fire discharges flame and hot gases into the corridor, causing a radiant heat energy exposure to the floor. It has been shown that the level of energy radiating onto the floor is a significant factor in determining whether progressive flaming will occur. NFPA 253 and ASTM E 648 measure the minimum energy required on the floor covering to sustain flame, measured in W/cm<sup>2</sup>. This minimum value is the *critical radiant flux*. The flooring radiant panel test, therefore, measures a floor covering’s tendency to spread flames where located in a corridor and exposed to flame and hot gases from a room fire.

Interior floor finishes must be tested as proposed for use. For example, if a carpet is to be used with a separate underlayment, the carpet must be tested as such. The flooring radiant panel test specifies that a carpet is permitted to be tested using either the standard underlayment specified in NFPA 253, ASTM E 648, or the actual underlayment proposed for use. Data generated using the standard underlayment is intended to permit the tested carpet to be used over any other underlayment. Where assembly tests are conducted with other than the standard underlayment, the results of such tests are valid only for the specific combination tested.

Floor coverings are not regulated on the basis of smoke generation. Smoke development limits are not believed to be practical or necessary, because floor coverings generally will not contribute to a fire until the fire has grown to large proportions. The minimal benefits achieved by imposing smoke development limits do not usually warrant such regulation. In addition, it is not considered practical to regulate on the basis of smoke development, because no regulatory test method that exists has been shown to be capable of producing data that correlates with the performance of products in actual fires.

**10.2.7.4** Interior floor finishes shall be grouped in the classes specified in 10.2.7.4.1 and 10.2.7.4.2 in accordance with the critical radiant flux requirements.

**10.2.7.4.1 Class I Interior Floor Finish.** Class I interior floor finish shall have a critical radiant flux of not less than 0.45 W/cm<sup>2</sup>, as determined by the test described in 10.2.7.3.

**10.2.7.4.2 Class II Interior Floor Finish.** Class II interior floor finish shall have a critical radiant flux of not less than 0.22 W/cm<sup>2</sup>, but less than 0.45 W/cm<sup>2</sup>, as determined by the test described in 10.2.7.3.

The greater its critical radiant flux value, the greater the resistance of a floor finish to flame propagation. Thus, a Class I interior floor finish with a critical radiant flux of 0.45 W/cm<sup>2</sup> or greater should perform better under fire conditions than a Class II interior floor finish material with its lesser critical radiant flux value

range of 0.22 W/cm<sup>2</sup> to less than 0.45 W/cm<sup>2</sup>. Contrast this classification with that of interior wall and ceiling interior finish materials in 10.2.3.4, in which higher flame spread ratings generally denote poorer performance under fire conditions.

**10.2.7.5** Wherever the use of Class II interior floor finish is required, Class I interior floor finish shall be permitted.

### 10.2.8 Automatic Sprinklers.

**10.2.8.1** Other than as required in 10.2.4, where an approved automatic sprinkler system is installed in accordance with Section 9.7, Class C interior wall and ceiling finish materials shall be permitted in any location where Class B is required, and Class B interior wall and ceiling finish materials shall be permitted in any location where Class A is required.

**10.2.8.2** Where an approved automatic sprinkler system is installed in accordance with Section 9.7, throughout the fire compartment or smoke compartment containing the interior floor finish, Class II interior floor finish shall be permitted in any location where Class I interior floor finish is required, and where Class II is required, the provisions of 10.2.7.2 shall apply.

Fire testing and actual fire experience have shown that automatic sprinklers prevent flame spread across the surface of a wall, ceiling, or floor covering so as to prevent flashover [see commentary following 10.1.3.2(2)]. Flame spread limits (applicable to interior wall and ceiling finishes) and critical radiant flux limits (applicable to interior floor finishes) are more lenient in areas protected by an automatic sprinkler system. However, there is a value beyond which the potential for flame spread becomes unacceptably high. For example, in occupancies with the most lenient interior finish requirements, which include fully sprinklered buildings, interior wall and ceiling finishes must meet the criteria for Class C materials.

Note that the provisions of 10.2.8.1 and 10.2.8.2 apply, unless specifically prohibited elsewhere in the Code. For an example of an occupancy chapter prohibiting the interior finish requirements from being further relaxed based on sprinkler protection, see 22.3.3.2 and 22.3.3.3.2, applicable to new detention and correctional occupancies. All new detention and correctional occupancies are required to be sprinklered (see 22.3.5.2). The interior finish limitations established in 22.3.3.2 and 22.3.3.3.2 are based on the presence of sprinklers. The prohibition on use of 10.2.8.1 and 10.2.8.2 keeps the user from taking a second, unjustified credit for the sprinklers.

## 10.3 Contents and Furnishings

Section 10.3 provides a detailed menu of provisions that apply to contents and furnishings (e.g., draperies, upholstered furniture, and mattresses) that can be adopted singly, in various combinations, or in their entirety in accordance with an occupancy's

individual operating features requirements. These requirements typically appear in Section \_\_\_\_7 of the applicable occupancy chapter. For example, the provisions for detention and correctional occupancies (22.7.4 and 23.7.4) make extensive, mandatory use of all provisions outlined in the Section 10.3 menu. Provisions for residential board and care occupancies (32.7.5, 33.7.5, A.32.7.5, and A.33.7.5) make mandatory and advisory use of various menu items contained in Section 10.3.

**10.3.1\*** Where required by the applicable provisions of this Code, draperies, curtains, and other similar loosely hanging furnishings and decorations shall meet the flame propagation performance criteria contained in Test Method 1 or Test Method 2, as appropriate, of NFPA 701, *Standard Methods of Fire Tests for Flame Propagation of Textiles and Films*.

**A.10.3.1** Testing per NFPA 701, *Standard Methods of Fire Tests for Flame Propagation of Textiles and Films*, applies to textiles and films used in a hanging configuration. If the textiles are to be applied to surfaces of buildings or backing materials as interior finishes for use in buildings, they should be treated as interior wall and ceiling finishes in accordance with Section 10.2 of this Code, and they should then be tested for flame spread index and smoke developed index values in accordance with ASTM E 84, *Standard Test Method for Surface Burning Characteristics of Building Materials*, or ANSI/UL 723, *Standard for Test for Surface Burning Characteristics of Building Materials*, or for flame spread and flashover in accordance with NFPA 265, *Standard Methods of Fire Tests for Evaluating Room Fire Growth Contribution of Textile or Expanded Vinyl Wall Coverings on Full Height Panels and Walls*. Films and other materials used as interior finish applied to surfaces of buildings should be tested for flame spread index and smoke developed index values in accordance with ASTM E 84 or ANSI/UL 723 or for heat and smoke release and flashover in accordance with NFPA 286, *Standard Methods of Fire Tests for Evaluating Contribution of Wall and Ceiling Interior Finish to Room Fire Growth*.

The test results from NFPA 701 are suitable for classification purposes but should not be used as input into fire models, because they are not generated in units suitable for engineering calculations.

The testing requirements of NFPA 701, *Standard Methods of Fire Tests for Flame Propagation of Textiles and Films*, measure the level of hazard posed by draperies and other loosely hanging fabrics and films. NFPA 701 describes procedures for an intermediate-scale test (referred to as Test Method 1) and a large-scale test (referred to as Test Method 2). The applicable test method is determined, in part, by the weight of the material per unit area (i.e., areal density). Both tests involve applying a flame to a vertically positioned sample for a specified time. Upon removal of the flame-producing burner, the sample must self-extinguish and must not have charred beyond a specified distance in order to pass the test. Additionally, with the intermediate-scale test, a specified maximum percent weight loss must not be exceeded.

Exhibit 10.7

NFPA 701 test sample in folds.

Exhibit 10.7 illustrates a representative setup for a folded test sample for the large-scale (Test Method 2) test from NFPA 701. The hanging textile sample is approximately 47 in. (1200 mm) long.

### 10.3.2 Smoldering Ignition of Upholstered Furniture and Mattresses.

**10.3.2.1\* Upholstered Furniture.** Newly introduced upholstered furniture, except as otherwise permitted by Chapters 11 through 43, shall be resistant to a cigarette ignition (i.e., smoldering) in accordance with one of the following:

- (1) The components of the upholstered furniture shall meet the requirements for Class I when tested in accordance with NFPA 260, *Standard Methods of Tests and Classification System for Cigarette Ignition Resistance of Components of Upholstered Furniture*.
- (2) Mocked-up composites of the upholstered furniture shall have a char length not exceeding 1½ in. (38 mm) when tested in accordance with NFPA 261, *Standard Method of Test for Determining Resistance of Mock-Up Upholstered Furniture Material Assemblies to Ignition by Smoldering Cigarettes*.

**A.10.3.2.1** The Class I requirement associated with testing in accordance with NFPA 260, *Standard Methods of Tests and Classification System for Cigarette Ignition Resistance of Components of Upholstered Furniture*, and the char length of not more than 1½ in. (38 mm) required with testing in accordance with NFPA 261, *Standard Method of Test for Determining Resistance of Mock-Up Upholstered Furniture Material Assemblies to Ignition by Smoldering Cigarettes*, are indicators that the furniture item or mattress is resistant to a cigarette ignition. A fire that smolders for an excessive period of time without flaming can reduce the tenability within the room or area of fire origin without

developing the temperatures necessary to operate automatic sprinklers.

The test results from NFPA 260 and from NFPA 261 are suitable for classification purposes but should not be used as input into fire models because they are not generated in units suitable for engineering calculations.

Until recently, NFPA 260 was equivalent to ASTM E 1353, *Standard Test Methods for Cigarette Ignition Resistance of Components of Upholstered Furniture*, and NFPA 261 was equivalent to ASTM E 1352, *Standard Test Method for Cigarette Ignition Resistance of Mock-Up Upholstered Furniture Assemblies*. However, that changed when NFPA 260 and NFPA 261 adopted the new NIST standard reference material (SRM 1196) as the igniting cigarette and ASTM E 1352 and ASTM E 1353 did not, meaning that ASTM E 1352 and ASTM E 1353 use commercial cigarettes that are low-ignition propensity and have a low likelihood of properly assessing smoldering potential.

**10.3.2.2\* Mattresses.** Newly introduced mattresses, except as otherwise permitted by Chapters 11 through 43, shall have a char length not exceeding 2 in. (51 mm) when tested in accordance with 16 CFR 1632, “Standard for the Flammability of Mattresses and Mattress Pads” (FF 4-72).

**A.10.3.2.2** The char length of not more than 2 in. (51 mm) required in 16 CFR 1632, “Standard for the Flammability of Mattresses and Mattress Pads” (FF 4-72), is an indicator that the mattress is resistant to a cigarette ignition. United States federal regulations require mattresses in this country to comply with 16 CFR 1632.

The provisions of 10.3.2 address ignition by cigarettes or other smoldering sources in an attempt to reduce the incidence of fires involving upholstered furniture and mattresses. Such ignition sources can smolder for considerable periods before producing flaming ignition.

Note that the formatting of 10.3.2.1 and 10.3.2.2 changed for the 2006 edition of the Code to require cigarette ignition testing of newly introduced upholstered furniture and newly introduced mattresses for all occupancies unless “otherwise permitted by Chapters 11 through 43.” In earlier editions, the provisions were formatted to apply only where the occupancy chapter required such compliance. The cigarette ignition testing of upholstered furniture and mattresses is exempted for the following occupancies:

1. Day-care homes (16.7.4.4, 17.7.4.4)
2. Health care occupancies, if sprinklered (18.7.5.2, 18.7.5.4, 19.7.5.2, 19.7.5.4)
3. Ambulatory health care occupancies, if sprinklered (20.7.5.2, 20.7.5.3, 21.7.5.2, 21.7.5.3)
4. One- and two-family dwellings (24.3.3.4)
5. Lodging or rooming houses (26.7.1.1)
6. Apartment buildings (30.7.2.1, 31.7.2.1)
7. Residential board and care occupancies, with smoke alarm in sleeping room (32.7.5.2.2, 32.7.5.3.2, 33.7.5.2.2, 33.7.5.3.2)

8. Mercantile occupancies (36.7.5, 37.7.5)
9. Business occupancies (38.7.5, 39.7.5)
10. Industrial occupancies (40.7.1)
11. Storage occupancies (42.9.1)

The following fire test methods address the cigarette ignition resistance of upholstered furniture:

1. NFPA 260, *Standard Methods of Tests and Classification System for Cigarette Ignition Resistance of Components of Upholstered Furniture*<sup>31</sup>
2. NFPA 261, *Standard Method of Test for Determining Resistance of Mock-Up Upholstered Furniture Material Assemblies to Ignition by Smoldering Cigarettes*<sup>32</sup>

One federal test method that is specified for judging the cigarette ignition resistance of mattresses is 16 CFR 1632, "Standard for the Flammability of Mattresses and Mattress Pads."<sup>33</sup> When purchasing upholstered furniture, consumers should check for flammability labeling. See [Exhibit 10.8a](#) and [Exhibit 10.8b](#) for a representative flammability hangtag found on upholstered furniture. The hangtag is produced by the Upholstered Furniture Action Council (UFAC), a voluntary furniture manufacturing

industry association. The UFAC hangtag program, developed in 1982, was designed to help reduce the number of cigarette-ignited fires in upholstered furniture. Manufacturers that participate in the program — and use the UFAC hangtags — agree to meet the construction criteria outlined by the program (which essentially is testing for compliance with NFPA 260). The hangtag, which is applied by the manufacturer to the finished piece of furniture at the factory, indicates to the consumer that the furniture meets the specified ignition resistance criteria.

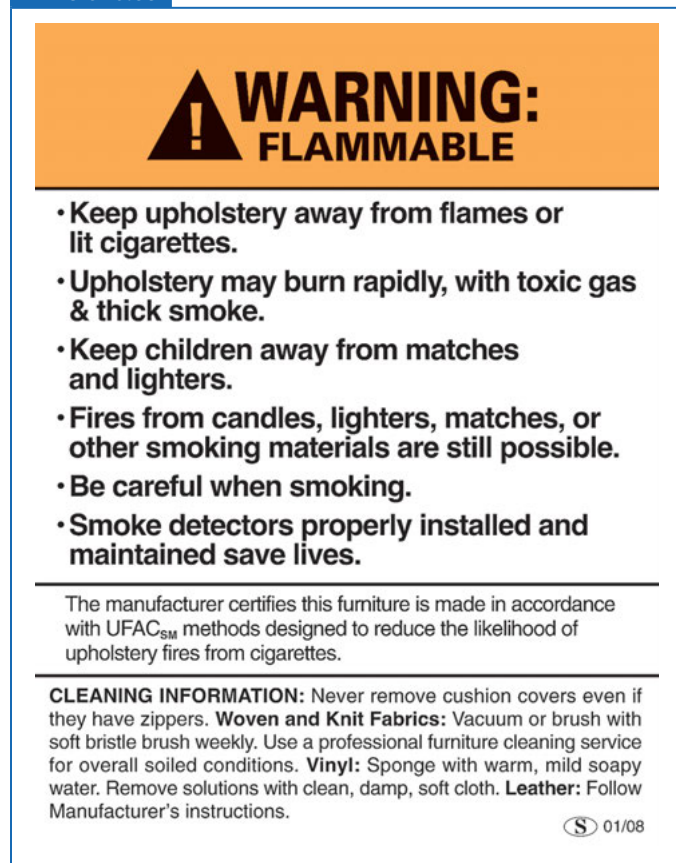

NFPA 260 tests individual components of upholstered furniture, such as cover fabric, interior fabric, welt cord, filling/padding, decking materials, and barrier materials. Specimens of the component to be tested are assembled with specimens of standardized materials to create a miniature horizontal base panel and vertical panel tester, a mocked-up arrangement that simulates the junction and surrounding area of a seat cushion and back cushion in a piece of upholstered furniture. Standardizing all the components of the mocked-up tester, except the component being tested, allows the test to measure the ignition resistance of the test component. Components that meet the test criteria are designated as Class I materials. Components that do not meet the test criteria are designated as Class II materials.

Exhibit 10.8a

Upholstered furniture flammability hangtag — front. (Courtesy of the Upholstered Furniture Action Council)

Exhibit 10.8b

Upholstered furniture flammability hangtag — back. (Courtesy of the Upholstered Furniture Action Council)

Upholstered furniture constructed from components that individually received a Class I designation is judged to be resistant to cigarette ignition without testing the actual combination of materials. Cigarette ignition-resistant upholstered furniture can also be constructed using Class II cover fabric materials over conventional polyurethane foam cushions if a Class I barrier material is used between the Class II fabric and the conventional foam cushion.

NFPA 261 tests a mocked-up assembly consisting of all the actual components that will be used to construct the piece of upholstered furniture, rather than testing the components individually. The test procedure specifies that a char length is to be measured and reported. There are no pass/fail criteria within the document, so 10.3.2.1(2) specifies that the char length not exceed 1½ in. (38 mm) if the mocked-up assembly is to be considered resistant to cigarette ignition.

NFPA 260 and NFPA 261 address the cigarette ignition resistance of upholstered furniture; 16 CFR 1632 addresses the cigarette ignition resistance of mattresses. For this test method, 10.3.2.2 establishes that a char length not exceeding 2 in. (51 mm) qualifies the mattress as resistant to cigarette ignition.

**10.3.3\*** Where required by the applicable provisions of this *Code*, upholstered furniture, unless the furniture is located in a building protected throughout by an approved automatic sprinkler system, shall have limited rates of heat release when tested in accordance with ASTM E 1537, *Standard Test Method for Fire Testing of Upholstered Furniture*, as follows:

- (1) The peak rate of heat release for the single upholstered furniture item shall not exceed 80 kW.
- (2) The total heat released by the single upholstered furniture item during the first 10 minutes of the test shall not exceed 25 MJ.

**A.10.3.3** The intent of the provisions of 10.3.3 is as follows:

- (1) The peak heat release rate of not more than 80 kW by a single upholstered furniture item was chosen based on maintaining a tenable environment within the room of fire origin, and the sprinkler exception was developed because the sprinkler system helps to maintain tenable conditions, even if the single upholstered furniture item were to have a peak rate of heat release in excess of 80 kW.
- (2) The total heat release of not more than 25 MJ by the single upholstered furniture item during the first 10 minutes of the test was established as an additional safeguard to protect against the adverse conditions that would be created by an upholstered furniture item that released its heat in other than the usual measured scenario, and the following should also be noted:
  - (a) During the test for measurement of rate of heat release, the instantaneous heat release value usually peaks quickly and then quickly falls off, so as to create a triangle-shaped curve.

- (b) In the atypical case, if the heat release were to peak and remain steady at that elevated level, as opposed to quickly falling off, the 80 kW limit would not ensure safety.
- (c) Only a sprinkler exception is permitted in lieu of the test because of the ability of the sprinkler system to control the fire.

Actual test results for heat, smoke, and combustion product release from ASTM E 1537, *Standard Test Method for Fire Testing of Upholstered Furniture*, might be suitable for use as input into fire models for performance-based design. Furthermore, California Technical Bulletin 133, “Flammability Test Procedure for Seating Furniture for Use in Public Occupancies,” includes pass/fail criteria for a single upholstered furniture item of 80 kW peak heat release rate and 25 MJ total heat release over the first 10 minutes of the test.

The provisions of 10.3.2 address only one important property of upholstered furniture and mattresses — their resistance to cigarette ignition. The provisions of 10.3.3 and 10.3.4 supplement those provisions by addressing rates of heat release. Different combustible materials vary in their potential to produce heat. Some plastic materials, for example, have twice as much potential heat per weight of material as wood. However, if a material with twice the potential heat were to burn only half as fast as a material with lower potential, the two materials would liberate about the same amount of heat during any given period and create approximately equivalent hazards. If one material with a heat potential approximately equal to another material were to burn twice as fast as the other, it would liberate about twice as much heat during any given period and, thus, create a greater hazard than the slower burning material. Therefore, the property of a material or group of materials expressed by a rate of heat release is important in regulating the combustibility of upholstered furniture and mattresses for use in nonsprinklered areas.

It is noted that, in the 2009 edition of the *Code*, the values in A.10.3.3 differed from those in the actual *Code* requirement of 10.3.3. The *Code* values were revised for the 2009 edition to correspond with the values found in California Technical Bulletin 133<sup>34</sup>; the associated annex text was inadvertently overlooked. The values were corrected for the 2012 and subsequent editions. The material in A.10.3.3 describes the intent of the rates of heat release provisions, which is to prevent any single furniture item from causing room flashover. The material in A.10.3.3 also explains how automatic sprinklers, in certain cases, can serve to provide the desired level of safety in lieu of a low rate of heat release.

**10.3.4\*** Where required by the applicable provisions of this *Code*, mattresses, unless the mattress is located in a building protected throughout by an approved automatic sprinkler system, shall have limited rates of heat release when tested in accordance with ASTM E 1590, *Standard Test Method for Fire Testing of Mattresses*, as follows:

- (1) The peak rate of heat release for the mattress shall not exceed 100 kW.
- (2) The total heat released by the mattress during the first 10 minutes of the test shall not exceed 25 MJ.

**A.10.3.4** The intent of the provisions of 10.3.4 is as follows:

- (1) The peak heat release rate of not more than 100 kW by a single mattress was chosen based on maintaining a tenable environment within the room of fire origin, and the sprinkler exception was developed because the sprinkler system helps to maintain tenable conditions, even if the single mattress were to have a peak rate of heat release in excess of 100 kW.
- (2) The total heat release of not more than 25 MJ by the single mattress during the first 10 minutes of the test was established as an additional safeguard to protect against the adverse conditions that would be created by a mattress that released its heat in other than the usual measured scenario, and the following should also be noted:
  - (a) During the test for measurement of rate of heat release, the instantaneous heat release value usually peaks quickly and then quickly falls off, so as to create a triangle-shaped curve.
  - (b) In the atypical case, if the heat release were to peak and remain steady at that elevated level, as opposed to quickly falling off, the 100 kW limit would not ensure safety.
  - (c) Only a sprinkler exception is permitted in lieu of the test because of the ability of the sprinkler system to control the fire.

Actual test results for heat, smoke, and combustion product release from ASTM E 1590, *Standard Test Method for Fire Testing of Mattresses*, might be suitable for use as input into fire models for performance-based design. Furthermore, California Technical Bulletin 129, “Flammability Test Procedure for Mattresses for Use in Public Buildings,” includes pass/fail criteria for a single mattress of 100 kW peak heat release rate and 25 MJ total heat release over the first 10 minutes of test.

See the commentary following A.10.3.3.

It is noted that, in the 2009 edition of the *Code*, the values in A.10.3.4 differed from those in the actual *Code* requirement of 10.3.4. The *Code* values were revised for the 2009 edition to correspond with the values found in California Technical Bulletin 129<sup>35</sup>; the associated annex text was inadvertently overlooked. The values were corrected for the 2012 and subsequent editions. The material in A.10.3.4 describes the intent of the rates of heat release provisions, which is to prevent any single furniture item from causing room flashover. The material in A.10.3.4 also explains how automatic sprinklers, in certain cases, can serve to provide the desired level of safety in lieu of a low rate of heat release.

**10.3.5\*** Furnishings or decorations of an explosive or highly flammable character shall not be used.

**A.10.3.5** Christmas trees that are not effectively flame-retardant treated, ordinary crepe paper decorations, and pyroxylin plastic decorations might be classified as highly flammable.

The *Code* relies on the authority having jurisdiction to exercise judgment in determining whether materials are of an explosive or highly flammable nature.

**10.3.6** Fire-retardant coatings shall be maintained to retain the effectiveness of the treatment under service conditions encountered in actual use.

See NFPA 703, *Standard for Fire Retardant-Treated Wood and Fire-Retardant Coatings for Building Materials*.

**10.3.7\*** Where required by the applicable provisions of this *Code*, furnishings and contents made with foamed plastic materials that are unprotected from ignition shall have a heat release rate not exceeding 100 kW when tested in accordance with UL 1975, *Standard for Fire Tests for Foamed Plastics Used for Decorative Purposes*, or when tested in accordance with NFPA 289, *Standard Method of Fire Test for Individual Fuel Packages*, using the 20 kW ignition source.

**A.10.3.7** Neither UL 1975, *Standard for Fire Tests for Foamed Plastics Used for Decorative Purposes*, nor NFPA 289, *Standard Method of Fire Test for Individual Fuel Packages*, is intended for evaluating interior wall and ceiling finish materials. Actual test results for heat, smoke, and combustion product release from UL 1975 or from NFPA 289 might be suitable for use as input into fire models intended for performance-based design.

### 10.3.8 Lockers.

**10.3.8.1 Combustible Lockers.** Where lockers constructed of combustible materials other than wood are used, the lockers shall be considered interior finish and shall comply with Section 10.2, except as permitted by 10.3.8.2.

**10.3.8.2 Wood Lockers.** Lockers constructed entirely of wood and of noncombustible materials shall be permitted to be used in any location where interior finish materials are required to meet a Class C classification in accordance with 10.2.3.

The provisions of 10.3.8 correspond with the provision of 10.2.1.6, which specifies that combustible lockers are considered interior finish. Where lockers are comprised of combustible materials other than wood, they must be tested as required by 10.2.3. Where lockers are made of wood, or a combination of wood and noncombustible materials, they are permitted to be installed wherever the *Code* permits Class C wall and ceiling finish materials with no additional testing.

### 10.3.9 Containers for Waste, or Linen.

**10.3.9.1** Where required by **Chapters 11** through **43**, newly introduced containers for waste or linen, with a capacity of 20 gal (75.7 L) or more, shall meet both of the following:

- (1) Such containers shall be provided with lids.
- (2) Such containers and their lids shall be constructed of non-combustible materials or of materials that meet a peak rate of heat release not exceeding 300 kW/m<sup>2</sup> when tested at an incident heat flux of 50 kW/m<sup>2</sup> in the horizontal orientation and at a thickness as used in the container but not less than ¼ in. (6.3 mm), in accordance with ASTM E 1354, *Test Method for Heat and Visible Smoke Release Rates for Materials and Products Using an Oxygen Consumption Calorimeter*.

**10.3.9.2** Where required by **Chapters 11** through **43**, newly introduced metal wastebaskets and other metal waste, or linen containers with a capacity of 20 gal (75.7 L) or more shall be listed in accordance with ANSI/UL 1315, *Standard for Safety for Metal Waste Paper Containers*, and shall be provided with a noncombustible lid.

The requirements of **10.3.9.1** and **10.3.9.2** are formatted such that they apply only where required by **Chapters 11** through **43**. Although some occupancy chapters specifically state the provisions of **10.3.9** do not apply, and other chapters are silent on the issue, the net result is that no occupancy chapter mandates compliance with either **10.3.9.1** or **10.3.9.2**. It should not be inferred that compliance with **10.3.9** is mandated where it is not specifically exempted.

# Special Structures and High-Rise Buildings

**Chapter 11** is formatted differently from the other chapters of the *Code*. It is the last of the core chapters that precedes the occupancy chapters. Its scope is potentially applicable to all occupancies. Each subsection is targeted to specific special structures or *unusual* surroundings within which a *usual* occupancy might exist. The facilities to which **Chapter 11** provisions might be applied range from a refinery petroleum-cracking plant to an air traffic control tower. While the life safety and functional use considerations of these properties might, at times, seem to conflict, **Chapter 11** provides the necessary guidance to make them safe as well as functional.

Examples of usual occupancies housed in unusual surroundings or special structures include a large convention center located on a pier, in which the facility is surrounded by water on three sides, and a storage facility located completely below ground level. **Exhibit 11.1** depicts an air traffic control tower, which is an example of a usual occupancy in an unusual structure.

**Exhibit 11.1**

Air traffic control tower at Denver International Airport. (Photo courtesy of Denver International Airport)

The authority having jurisdiction (AHJ) should ensure that any engineered solutions to the special structure's inherent egress deficiencies provide an overall level of life safety equivalent to that specified by the requirements of the occupancy chapter that applies to the structure's use. In some cases, a structure might be so unusual that the only practical option is a complete performance-based design in accordance with **Chapter 5**.

**Chapter 11** also regulates water-surrounded structures, vehicles and vessels, and limited access (referred to as *windowless* prior to the 2003 edition of the *Code*) and underground structures. These provisions apply, regardless of the occupancy classification. For example, a permanently moored ship that is used as a hotel with restaurants and other entertainment facilities must comply with **Chapter 12** or **Chapter 13** for assembly occupancies, and **Chapter 28** or **Chapter 29** for hotels and dormitories, as appropriate, by virtue of the language in **11.6.2**. The Queen Mary, which has been permanently moored in Long Beach, California, since 1967, is an example of such an occupancy. See **Exhibit 11.2**.

**Section 11.8** presents a series of unique provisions applicable to high-rise buildings. The various occupancy chapters might mandate the use of some, all, or none of those provisions. **Section 11.8** applies to all new high-rise buildings and existing high-rise buildings as specified by the applicable existing occupancy chapters.

**Sections 11.9** through **11.11** provide a series of requirements applicable to membrane structures and tents. Similar

**Exhibit 11.2**

The Queen Mary in Long Beach, CA. (Photo courtesy of the Queen Mary, Long Beach, CA)

requirements were originally contained in NFPA 102, *Standard for Grandstands, Folding and Telescopic Seating, Tents, and Membrane Structures*.<sup>1</sup> However, the requirements for such seating are now within the scope of this Code (and that of NFPA 5000®, *Building Construction and Safety Code*<sup>2</sup>). As such, NFPA 102 is now extracted, in its entirety, from NFPA 101 and NFPA 5000.

## 11.1 General Requirements

**11.1.1 Application.** The requirements of Sections 11.1 through 11.11 shall apply to occupancies regulated by Chapters 12 through 42 that are in a special structure. The applicable provisions of Chapters 12 through 42 shall apply, except as modified by this chapter. Section 11.8 shall apply to high-rise buildings only where specifically required by Chapters 12 through 42.

Occupancies in special structures can pose a challenge to life safety. Sections 11.1 through 11.6 are intended to supplement the requirements of the occupancy chapters (Chapters 12 through 42); their provisions might serve as requirements that must be satisfied in addition to those found in the applicable occupancy chapter. For example, 11.5.2.2 contains additional provisions that apply to a pier used for other than cargo handling or storage. Therefore, in the case of an amusement pier, the requirements of Chapter 12 or Chapter 13 for assembly occupancies would apply, as well as those of 11.5.2.2.

The provisions of Chapter 11 also might take the form of a modification of a requirement that is permitted to be used for an occupancy in a special structure but that would not be permitted in a usual structure housing the same occupancy. For example, if a business occupancy is housed in a tower, 11.3.2.4.1 permits a single exit from the tower under a strict set of conditions. However, if a similar business occupancy is located on an upper floor of a multistory building that is not a tower, Chapter 38 or Chapter 39 would require that two exits be provided on the floor housing the business occupancy. In other words, Chapter 11 might offer an exemption based on the inherent difficulty of providing two remote exits from a tower. Yet, the exemption does not constitute a waiver that ignores life safety; rather, the exemption provides criteria and limitations that ensure a safe means of tolerating a single exit.

In addition to the provisions applicable to an occupancy via its appropriate occupancy chapter (Chapters 12 through 42), occupancies housed in underground and limited access structures must comply with the provisions of Section 11.7, which include the following:

1. Complete automatic sprinkler protection, unless certain criteria are met (see 11.7.3.4)
2. Emergency lighting (see 11.7.3.5)
3. Smoke venting (in underground structures only; see 11.7.4.3)
4. Directional signage for egress paths (in underground structures only; see 11.7.4.4)

An occupancy in a high-rise building must comply with the requirements of Section 11.8 only to the degree specified by the applicable occupancy chapter. All new high-rise buildings must comply with the full package of high-rise building provisions of Section 11.8 as referenced by the new occupancy chapters and provisions. For most existing buildings, the applicable occupancy chapter does not make mandatory use of any of the provisions of Section 11.8, although some require existing high-rise buildings to be sprinklered in accordance with Section 9.7 rather than 11.8.3.

Although the Code provisions present an essentially complete package of requirements for life safety, the provision of adequate means of egress from many special structures requires unique solutions. In many instances, engineered solutions will supplement the minimum provisions of Chapter 11 and the applicable occupancy chapter. However, the unique character of a structure should not become an excuse for reducing safety to life. The Code user is cautioned to exercise careful judgment when determining the egress requirements for special structures.

**11.1.2 Multiple Occupancies.** See 6.1.14.

**11.1.3 Definitions.**

**11.1.3.1 General.** For definitions see Chapter 3 Definitions.

**11.1.3.2 Special Definitions.** Special terms used in this chapter are located within each special structure section.

**11.1.4 Classification of Occupancy.** Occupancies regulated by Chapters 12 through 42 that are in special structures shall meet the requirements of those chapters, except as modified by this chapter.

**11.1.5 Classification of Hazard of Contents.** Classification of hazard of contents shall be in accordance with Section 6.2.

**11.1.6 Minimum Construction Requirements.** Minimum construction requirements shall be in accordance with the applicable occupancy chapter.

**11.1.7 Occupant Load.** The occupant load of special structures shall be based on the use of the structure as regulated by Chapters 12 through 42.

**11.1.8 Automatic Sprinkler Systems.** Where another provision of this chapter requires an automatic sprinkler system, the automatic sprinkler system shall be installed in accordance with the subparts of 9.7.1.1 as permitted by the applicable occupancy chapter.

## 11.2 Open Structures

**11.2.1 Application.**

**11.2.1.1 General.** The provisions of Section 11.1 shall apply.

**11.2.1.2 Definition — Open Structure.** See 3.3.272.6.

### 11.2.2\* Means of Egress.

**A.11.2.2** Escape chutes, controlled descent devices, and elevators are permitted to provide escape routes in special structures; however, they should not be substituted for the provisions of this Code.

**11.2.2.1 General.** The means of egress provisions of the applicable occupancy chapter, Chapters 12 through 42, shall apply, except as modified by 11.2.2.2 through 11.2.2.10.

#### 11.2.2.2 Means of Egress Components.

**11.2.2.2.1 Fire Escape Ladders.** Open structures that are designed for occupancy by not more than three persons shall be permitted to be served by fire escape ladders complying with 7.2.9.

#### 11.2.2.2.2 Reserved.

**11.2.2.3 Capacity of Means of Egress.** Open structures shall be exempt from the requirements for capacity of means of egress.

Paragraph 11.2.2.3 recognizes the multiple means of egress paths available from open structures, such as those found in petrochemical and process industries. An open structure is typically an access platform to the equipment it surrounds or supports. Normal occupancy is very limited in number and occasional in frequency. If a fire blocks one means of egress, a number of alternate means of egress remain available. An escape route is provided by the fixed means of egress, and rescue is possible from any portion of the structure by use of the emergency procedures of fire-fighting personnel. The potential for exposure of portions of the structure not involved in a fire is minimal, because flames, heat, and smoke are safely dispersed directly into the atmosphere and not into the uninvolved portions of the structure.

#### 11.2.2.4 Number of Means of Egress.

**11.2.2.4.1\*** Open structures at the finished ground level are exempt from the requirements for number of means of egress.

**A.11.2.2.4.1** The grade level of open structures, which by their very nature contain an infinite number of means of egress, are exempt from the requirements for number of means of egress.

**11.2.2.4.2** Open structures occupied by not more than three persons, with travel distance of not more than 200 ft (61 m), shall be permitted to have a single exit.

**11.2.2.5 Arrangement of Means of Egress.** (No modifications.)

**11.2.2.6 Travel Distance to Exits.** Open structures shall be exempt from travel distance limitations.

**11.2.2.7 Discharge from Exits.** Open structures permitted to have a single exit per 11.2.2.4 shall be permitted to have 100

percent of the exit discharge through areas on the level of exit discharge.

**11.2.2.8 Illumination of Means of Egress.** Open structures shall be exempt from illumination of means of egress requirements.

**11.2.2.9 Emergency Lighting.** Open structures shall be exempt from emergency lighting requirements.

**11.2.2.10 Marking of Means of Egress.** Open structures shall be exempt from marking of means of egress requirements.

### 11.2.3 Protection.

**11.2.3.1 Protection of Vertical Openings.** Open structures shall be exempt from protection of vertical opening requirements.

**11.2.3.2 Protection from Hazards.** Every open structure, other than those structures with only occasional occupancy, shall have automatic, manual, or other protection that is appropriate to the particular hazard and that is designed to minimize danger to occupants in case of fire or other emergency before they have time to use the means of egress.

**11.2.3.3 Interior Finish.** (No modifications.)

**11.2.3.4 Detection, Alarm, and Communications Systems.** Open structures shall be exempt from requirements for detection, alarm, and communications systems.

**11.2.3.5 Extinguishing Requirements.** (No modifications.)

## 11.3 Towers

### 11.3.1 Application.

**11.3.1.1 General.** The provisions of Section 11.1 shall apply.

**11.3.1.2 Definition — Tower.** See 3.3.281.

#### 11.3.1.3 Use of Accessory Levels.

**11.3.1.3.1 Sprinklered Towers.** In towers protected throughout by an automatic sprinkler system in accordance with Section 9.7, the levels located below the observation level shall be permitted to be occupied only for the following uses that support tower operations:

- (1) Use as electrical and mechanical equipment rooms, including emergency power, radar, communications, and electronics rooms
- (2)\* Incidental accessory uses

**A.11.3.1.3.1(2)** The incidental accessory uses are intended to apply to small office spaces or lounge areas and similar uses that are used by tower employees.

**11.3.1.3.2** Electronic supervision of supervisory signals shall be provided in accordance with 9.7.2.1. Waterflow alarms shall be monitored in accordance with 9.7.2.2.

## 11.3.2 Means of Egress.

**11.3.2.1 General.** The means of egress provisions of the applicable occupancy chapter, **Chapters 12 through 42**, shall apply, except as modified by **11.3.2.2 through 11.3.2.10**.

### 11.3.2.2 Means of Egress Components.

**11.3.2.2.1 Fire Escape Ladders.** Towers, such as forest fire observation or railroad signal towers, that are designed for occupancy by not more than three persons shall be permitted to be served by fire escape ladders complying with **7.2.9**.

**11.3.2.2.2 Elevators.** Towers subject to occupancy by not more than 90 persons shall be permitted to use elevators in the means of egress in accordance with **7.2.13**.

### 11.3.2.3 Capacity of Means of Egress.

**11.3.2.3.1** Means of egress for towers shall be provided for the number of persons expected to occupy the space.

**11.3.2.3.2** Spaces not subject to human occupancy because of machinery or equipment shall be excluded from consideration.

### 11.3.2.4\* Number of Means of Egress.

**A.11.3.2.4** The Washington Monument in Washington, DC, is an example of a tower where it would be impracticable to provide a second stairway.

**11.3.2.4.1** Towers shall be permitted to have a single exit, provided that the following conditions are met:

- (1) The tower shall be subject to occupancy by fewer than 25 persons.
- (2) The tower shall not be used for living or sleeping purposes.
- (3) The tower shall be of Type I, Type II, or Type IV construction. (See **8.2.1**.)
- (4) The tower interior wall and ceiling finish shall be Class A or Class B.
- (5) No combustible materials shall be located within the tower, under the tower, or within the immediate vicinity of the tower, except necessary furniture.
- (6) No high hazard occupancies shall be located within the tower or within its immediate vicinity.
- (7) Where the tower is located above a building, the single exit from the tower shall be provided by one of the following:
  - (a) Exit enclosure separated from the building with no door openings to or from the building
  - (b) Exit enclosure leading directly to an exit enclosure serving the building, with walls and door separating the exit enclosures from each other, and another door allowing access to the top floor of the building that provides access to a second exit serving that floor

**Paragraph 11.3.2.4.1** permits a single means of egress from a tower if additional criteria are met. Determination of the total occupant load of a tower should be based on the actual number

of people expected to occupy the facility [see **11.3.2.4.1(1)**]. Limitations on the combustibility and interior finish of the structure are established, so that the potential exposure of the tower occupants to fire is minimal. Types I, II, and IV construction [see **11.3.2.4.1(3)**] are defined in *NFPA 5000, Building Construction and Safety Code*, and *NFPA 220, Standard on Types of Building Construction*.<sup>3</sup>

One difficulty associated with the requirements for exits in towers is the accurate determination of the level of exposure of the tower to combustible materials under, or in the immediate vicinity of, the structure. The authority having jurisdiction and other *Code* users should use careful judgment to ensure that arbitrary limitations are not established that excessively restrict the use of the tower. For example, a forest fire tower is usually located in a clearing in a large forest. The proximity of trees to the tower could be interpreted as constituting combustible materials in the immediate vicinity of the tower. Reasonable clearances between the tower and forest — such as a clear space of 50 ft to 100 ft (15 m to 30 m) — could be considered adequate separation for the life safety of the tower's occupants. Similar judgment is required where evaluating the clearance between high hazard occupancies and towers.

The provisions of **11.3.2.4.1(7)** are illustrated in **Exhibit 11.3**. Where the tower is located above a building, special precautions must be taken to prevent use of the tower's single means of egress from being compromised by a fire in the building below. In **Exhibit 11.3**, Part (a), the single exit stair enclosure for the tower is separated from the building by rated construction in accordance with **7.1.3.2**. Additionally, the single exit stair enclosure for the tower has no openings to the floors of the building above which the tower is positioned, thus preventing a fire on the building floors from entering the enclosure.

In **Exhibit 11.3**, Part (b), the single exit stair positioned above the building serves the tower. It provides direct access to the exit stair enclosure on the left, which also serves the building floors. If a fire prevents the use of the exit stair enclosure on the left, the tower stair allows tower occupants to traverse the top floor of the building and access a second exit stair enclosure on the right.

**11.3.2.4.2** Towers with 360-degree line-of-sight requirements shall be permitted to have a single means of egress for a distance of travel not exceeding 75 ft (23 m), or 100 ft (30 m) if the tower is protected throughout by an approved, supervised automatic sprinkler system in accordance with **Section 9.7**.

**11.3.2.4.3** Electronic supervision of sprinkler system supervisory signals shall be provided in accordance with **9.7.2.1** and waterflow alarms shall be monitored in accordance with **9.7.2.2**.

**11.3.2.5 Arrangement of Means of Egress.** (No modifications.)

**11.3.2.6 Travel Distance to Exits.** Towers where ladders are permitted by **11.3.2.2.1** shall be exempt from travel distance limitations.

Exhibit 11.3

Single exit from a tower.

**11.3.2.7 Discharge from Exits.** Towers permitted to have a single exit per 11.3.2.4 shall be permitted to have 100 percent of the exit discharge through areas on the level of exit discharge.

**11.3.2.8 Illumination of Means of Egress.** Towers where ladders are permitted by 11.3.2.2.1 shall be exempt from illumination of means of egress requirements.

#### 11.3.2.9 Emergency Lighting.

**11.3.2.9.1** Towers where ladders are permitted by 11.3.2.2.1 shall be exempt from emergency lighting requirements.

**11.3.2.9.2** Locations not routinely inhabited by humans shall be exempt from emergency lighting requirements.

**11.3.2.9.3** Structures occupied only during daylight hours, with windows arranged to provide the required level of illumination of all portions of the means of egress during such hours, shall be

exempt from emergency lighting requirements where approved by the authority having jurisdiction.

#### 11.3.2.10 Marking of Means of Egress.

**11.3.2.10.1** Towers where ladders are permitted by 11.3.2.2.1 shall be exempt from marking of means of egress requirements.

**11.3.2.10.2** Locations not routinely inhabited by humans shall be exempt from marking of means of egress requirements.

### 11.3.3 Protection.

#### 11.3.3.1 Protection of Vertical Openings.

**11.3.3.1.1** Towers where ladders are permitted by 11.3.2.2.1 shall be exempt from protection of vertical opening requirements.

**11.3.3.1.2** In towers where the support structure is open and there is no occupancy below the top floor level, stairs shall be permitted to be open with no enclosure required, or fire escape stairs shall be permitted.

**11.3.3.2 Protection from Hazards.** Every tower, other than structures with only occasional occupancy, shall have automatic, manual, or other protection that is appropriate to the particular hazard and that is designed to minimize danger to occupants in case of fire or other emergency before they have time to use the means of egress.

**11.3.3.3 Interior Finish.** (No modifications.)

**11.3.3.4 Detection, Alarm, and Communications Systems.** Towers designed for occupancy by not more than three persons shall be exempt from requirements for detection, alarm, and communications systems.

**11.3.3.5 Extinguishing Requirements.** (No modifications.)

**11.3.3.6 Corridors.** (No modifications.)

### 11.3.4 Additional Requirements for Air Traffic Control Towers.

The provisions of 11.3.4, which were new to the 2009 edition of the Code, provide additional requirements for an air traffic control tower (ATCT), which is defined in 3.3.281.1 as “an enclosed structure or building at airports with elevated levels for support of equipment and occupied for observation, control, operation, and signaling of aircraft in flight and on the ground” (see Exhibit 11.1 for an example of an ATCT). These criteria are intended to supplement the general tower provisions of Section 11.3, as well as the applicable occupancy chapter provisions (typically Chapters 38 and 39 for business occupancies); they recognize that conditions at ATCTs include critical public safety functions and unique occupancy conditions, such as the potential for delayed evacuation and limited occupant loads. The criteria for single-exit ATCTs in 11.3.4.4.1 are based on those agreed upon by the U.S. Department of Transportation’s Federal Aviation Administration (FAA) and the U.S. Department of Labor’s

Occupational Safety & Health Administration (OSHA). The level of protection afforded by life safety features, such as fire-resistive or noncombustible construction (11.3.4.3), smokeproof enclosures (11.3.4.4.5), fire alarm and detection systems (11.3.4.5.1), and automatic sprinklers (11.3.4.5.2), is deemed to be sufficient to accommodate the unique operational requirements for ATCTs that might otherwise compromise occupant life safety from fire.

**11.3.4.1 Definition — Air Traffic Control Tower.** See 3.3.281.1.

**11.3.4.2 Use of Accessory Levels.** The levels located below the observation level shall be permitted to be occupied only for the following uses that support tower operations:

- (1) Use as electrical and mechanical equipment rooms, including emergency and standby power, radar, communications, and electronics rooms
- (2)\* Incidental accessory uses
